A proposal was brought before the congress that a universal rule of the road should be adopted, all vehicles keeping to the left and passing on the right, as is done in England and certain portions of Continental Europe. The disturbance that would be caused by such a change prevented it being adopted, but it was significant that the proposal gained much favor among delegates of countries where the American rule of the road is in vogue, and that M. Millerand, minister of public works in France, expressed the opinion that later the whole world would have to come to the English method.

Among the other matters agreed to by the international conference was that no automobile should be permitted to travel in foreign countries allowing the use of its national registration tag unless in addition the cars carried special plates with letters indicative of the country of their origin.

Signals That Find Most Favor

A loud sounding horn was agreed upon as the proper signal to be used by an automobile, with mechanical hooters allowed in the open country. At nightfall every automobile must carry two lights in front and one at the rear. Dazzling headlights must not be used in towns.

A few modifications were made for the benefit of motorcyclists, the rear light being considered unnecessary, the size of registration numbers could be reduced and a reverse gear was not required.

All the governments signing the agreement resolved that in their countries a uniform system of road signs would be employed. These will be the four signs recently adopted by the international road congress in Paris, and originated by the Automobile Club of France. The warning is given by means of a figure, without any wording whatever. In addition to these four it was allowed to add a fifth not included in this series, to indicate a customs office or frontier station.

It is certain that this first conference will not be the last. The high standing of the delegates sent by the respective govrnments is an indication of the importance attached to the proceedings. The desire not only among automobilists but in official circles is to make automobile laws and regulations uniform throughout Europe, so that international touring may be as free from formalities as travel in the native land.

Up-to-Date Features of Radiators and Pumps

Part 2

By Thos. J. Fay

GEAR pumps have other characteristics and fortunately a series of tests were made at the Thomas plant at the time of making tests of centrifugal types, and since this is an assurance of equality of conditions, the gear-pump tests will be of greater value than would be possible were there chances of changing conditions. Fig. 11 represents the performance of the type of gear pump used on one of the 1909 Thomas models and the water in gallons per minute was in direct proportion to speed, thus showing that the pump was well made and that leakage was not a factor within the limits. The horsepower exerted was found nearly parallel to increase in head beyond 600 revolutions per minute and to increase at a rate in excess of the increase in capacity of the pump with increasing speed; the pump performance in view of the results differs but little from that of the centrifugal-pump test, in that the amount of water moved at speeds below 600 revolutions per minute is below the desired point and the increase is in direct proportion to speed. In the centrifugal pump the increase is a little more than in direct proportion to speed, but is nothing like what is usually supposed.

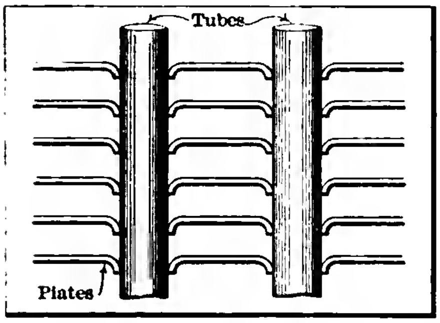

Fig. 7—Section showing how the gill-plates are flanged over tubes to increase surface of contact with tubes

As between the two types of pumps there is little or no choice; they both do the work under substantially the same conditions unless it is that the gear type of pump is more likely to make noise. When it comes to wear it is difficult to make any comparison at all for the reason that design features are likely to obscure the results so that a comparison will be futile. There is ample reason to believe that both types of pump last as long as the motor when they are properly designed and built. In conclusion of this phase of the subject it is just possible that Fig. 12 presents the efficiency of the gear type of pump and will add a desirable increment to the knowledge in store for future guidance of designers.

Pump and Radiator Must Be in Harmony—It is useless to employ a pump of large capacity unless the radiator is capable of abstracting all the heat that is taken from the motor. On the other hand, since the radiator should be large enough to do the required work, it is self-evident that the pump should move as much water as the radiator can handle and sponge all the heat units out of it that come from the motor. If the pump is sufficient in capacity the radiator will have to be larger for a given work assuming that steaming is to be avoided. It cannot be shown readily that there is much danger in adopting a pump that is too large, and in selecting a pump for this work, considering the small amount of power consumed in moving the water, it would seem to be the better choice to have the pump a little large for the work. The probabilities are that it is desirable to use a pump that will move 1.33 pounds of water per horsepower per minute when the motor is running at about 400 revolutions per minute. This is but approximation to be sure, but it is so near the requirement (on the safe side) that it is a better guess than to risk a restricted capacity of the pump and have to use a large radiator or put up with steaming.

Comparing the Thermo-Syphon System—The old idea of the thermo-syphon system of cooling was that it was the "system of natural circulation," which is true, perhaps, under certain well-defined conditions. In the radiator, as shown in Fig. 3, the circulation is far greater than that due to the natural difference in weight of heated and cooled water. In order to bring out the point to be made it will be necessary to present a sectional drawing of the radiator which was kindly furnished by the Regal Motor Car Company and is here given as Fig. 13. The water enters at a point near the top of the radiator from the motor (see section A) and is impelled by energy from steam which forms over the domes of the cylinders. When the water and entrained steam enter the pocket some of it passes up to the space b and the balance down to the lower chamber c. The water that passes up to the chamber b, together with the entrained steam, is reduced in temperature during its passage and it then passes down through the outside rows of tubes d. In its downward migration it is cooled more perfectly and is there mingled with the heated water which passes down directly from the pocket a to the chamber c. The cooled water passes along the pipe e back to the water jackets of the cylinders of the motor, thus completing the cycle.

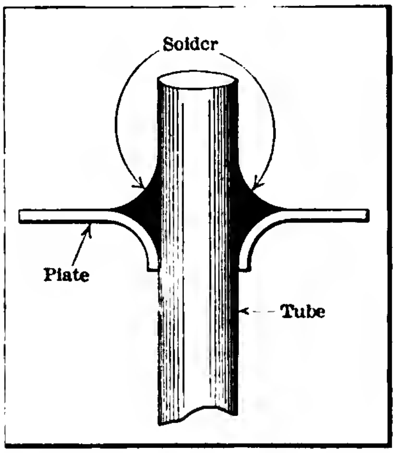

Fig. 8—Illustrating the way the solder runs down and forms a fillet at junction of tubes and plates, thus increasing conductivity

In this is evidence of the equivalent of a pump, it being the idea to utilize the energy in the steam. That steam does form over the surfaces of the water jacket is now a well-established fact and all that remained was to so contrive a radiator that advantage could be taken of this available energy. Of course, this system is thermo-syphon in name only, and while it matters very little as to the designation, even so, it more properly belongs to the "injector" family.

The true thermo-syphon radiator would be the same as shown in Fig. 2 were the pump omitted. In other

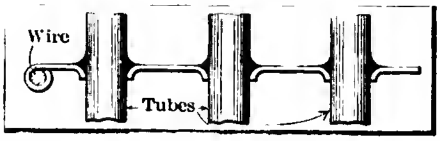

Fig. 9—Section depicting the wire binder in the plates to make them rigid and to enhance appearance

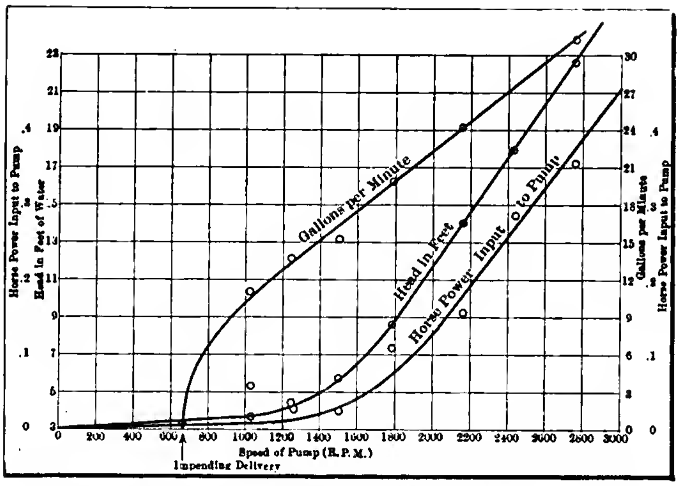

Fig. 10—Test of centrifugal pump used for water circulation by the Thomas Motor Company.

words, there is only two differences between radiators as used with a pump and when used without a pump—a, the radiator must be larger and advantageously placed if the pump is not used, and b, the piping system must be more commodious, so as to accomplish the desired results.

Determine the Ratio of Surfaces—After all the great question beyond an efficient radiator is to determine the ratio of flame-swept to radiating surface, and while this ratio will not be the same for thermo-syphon systems as it must be when an enforced circulation is taken advantage of, it should be ascertained with much certainty unless it is that the radiator can be fixed upon by trial of a number until the right size is found. By determining the exact flame-swept surface all the uncertainties are reduced to a minimum and dealing in horsepower rating becomes unnecessary. If account is taken of the wide disagreement between engineers when it comes to determining actual horsepower of the several makes of motors, it is easy enough to see that any such method of determining as to the required capacity of radiators is quite out of the question. Each case must be considered separately and the amount of power given full consideration.

In a general way it is possible to say that the limits of the ratio of radiating to flame-swept surface of cylinders will lie between one and two. In certain cases the situation was found to be as follows:

CASE "A"

Radiating surface (exterior of cylinder)......298 square inches
Flame-swept surface of cylinders.............168 square inches

$$\text{Ratio} = \frac{298}{168} = 1.78$$

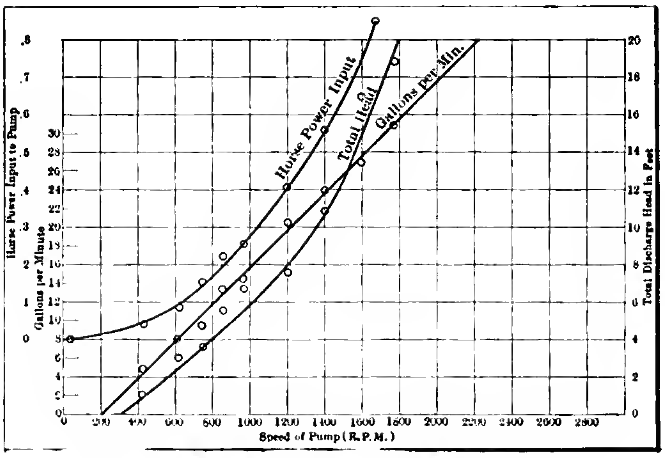

Fig. 11—Test of a gear pump used for water circulation; another Thomas undertaking

CASE "B"

Radiating surface (exterior of cylinder).......464 square inches
Flame-swept surface of cylinders...............273 square inches

$$\text{Ratio} = \frac{464}{273} = 1.70$$

In the above it is understood that the radiating surface of cylinders is that (covered with circulating water) outside and facing the flame-swept surface with the cylinder wall between.

The relation of radiating surface of radiators to radiating surface of cylinders will depend upon the effectiveness of the later and the efficiency of the former. If the radiator is efficient it is possible to realize good results with thirty-three times the cylinder radiating surface. If the radiator lacks in efficiency it may be necessary to increase to even 45 square inches of radiating surface per square inch of cylinder radiating surface.

What the Situation Portrays—The story, if it tells anything, rather goes to show that accessories (in the form of complete units) may be made by specialist quite as well, if not better, than in any other way. To bring about the best results, however, it is desirable to do the work in shops that are especially fitted out for the purpose and cost should be second to quality. This is not to infer that cost, if it is high, is a guarantee of quality;

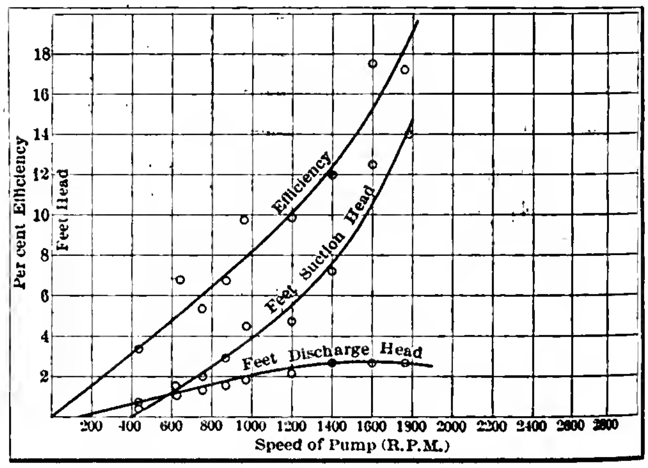

Fig. 12—Curve of efficiency of a gear pump used for water circulation as determined in the Thomas laboratory

on the contrary, the very increase in cost, if it is brought about by doing things in a bungling way, is a sign of absence of quality.

Referring to radiators in accessory shops, it is certain that a thorough investigation of the motor to be cooled is an absolute necessity and, as before stated, the flame-swept surface must be carefully determined. But this is not all; the compression must be taken into account on the ground that the temperature prevailing will not be the same for all compressions. Then, the timing is of importance, for, if the hot gases are retained for a lengthened period more heat will be absorbed by the jacket water, and as this heat is increased, so must the surface of the radiator be augmented, and this, too, in excess of the radiator surface which would be indicated by counting the area of flame-swept surface.

There is no reason why the timing question should complicate the situation very much, since it is possible to time all motors in such a way as to realize the best results, but there is but one way to prevent motorists from running on a retarded spark, and that is to so design the ignition system that the spark will be fixed. True, a fixed spark does not give the highest attainable results, but it does afford higher values than are usually attained by the average driver of a car. At all events, it is futile to charge the raditor with lack of ability if the motorist persists in running on a retarded spark, and this point should be explained to every motorist when he purchases a car.

Note.—144 pounds of jacket water per minute.

The test as above given was made by one of the makers of cars to ascertain as to the ability of the radiators of this make, and the excellent results realized sufficiently voices the situation to render further discussion along this line wholly unnecessary. The table shows, among other points of interest, that it took 25 minutes before the water reached a constant temperature, after which the radiator abstracted 1,431.4 B. T. U. of heat from the jacket water, with a difference in the water between inlet and outlet of 9.94 degrees Fahrenheit, working between the limits of 197 and 187 degrees Fahrenheit. The amount of water circulated was (as given in the table) 144 pounds. Since the temperature did not reach the maximum allowable in practice (the boiling point of water) it is a fair inference that the capacity of this radiator can be taken as about equal to 1,500 B. T. U. (British thermal units of heat) under the conditions of this test, considering round numbers.

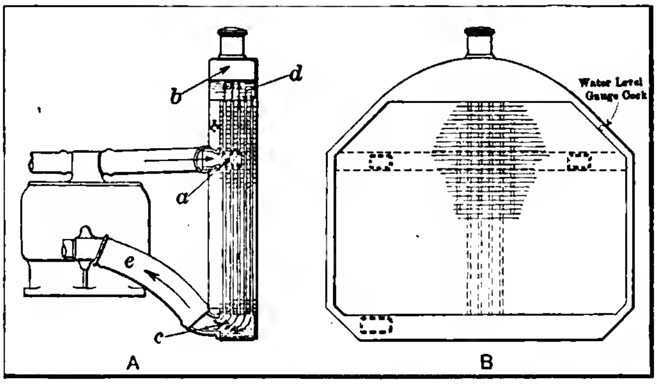

Fig. 13—Section of a Regal radiator offered to show how the water is directed under the force of steam

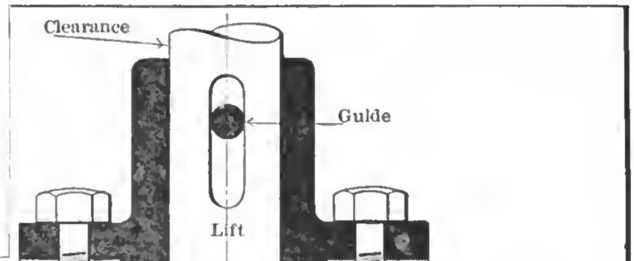
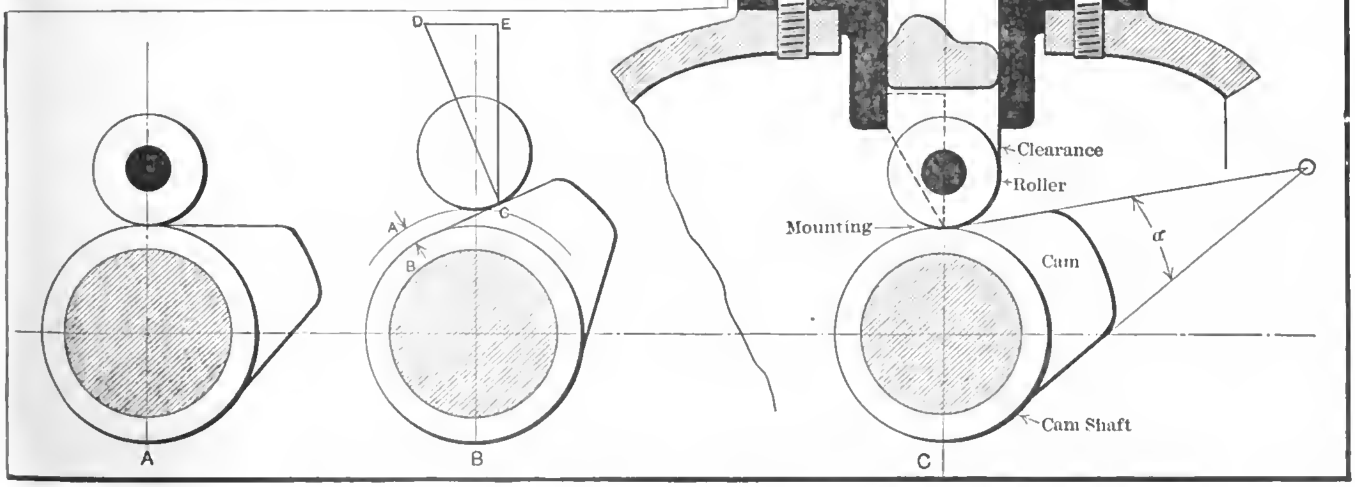
NOISE EMANATES FROM THE VALVE LIFTS

DIFFICULTY is frequently experienced in locating noises in and about the power plant, probably because there are so many of them that it is difficult in determining where to begin. The best way, perhaps, is to go about it in a systematic manner, starting with the most likely sources, as in the valve lifts, since in them the cause of the noise is of a mysterious nature. Referring to the accompanying figure. A depicts the lift-roller on the vertical center line just before the roller begins to mount the cam; and at B the roller has mounted the cam by an amount represented by the radial distance A B, thus bringing the roller where it contacts with the Cam at C and the line C D is at 90 degrees with the face of the cam, which brings the line C E out of the true plane of lifting by an amount equal to D E, but since C E is parallel to the lift, it follows that there will be a side pressure on the lift, the magnitude of which will be equal to D E if the vertical pressure is equal to C E, which pressure will be due to the gas pressure on the valve augmented by the pressure of the spring used to close the valve.

If the lift is not a snug fit in the guide it is a natural sequence that a noise will emanate from the lift every time the cam mounts the roller, and the manner in which this is brought about is best shown at C of the figure, where it will be seen that the lift in its bearing, having too much play, tilts diagonally and clearance is indicated at the two diagonal points effected. There is no take-up provided for valve-lift guides, and in order that they will not become noisy it is good practice to lubricate them, particularly in view of the manner in which the pressure comes on when the roller mounts the cam, for if play is engendered noise will follow and the only cure is to procure new parts.

The amount of noise which will follow if the lift becomes loose in the guide depends very largely upon the shape of the cam, diameter of the roller and length of the guide. If the motor has a plurality of cylinders the same trouble will be experienced with each cylinder and something of a clatter may be the due reward of allowing the guides to run without oil and with sand or other foreign substances present.





Showing How Lost Motion Creeps In if the Lifts Are Slack in the Guides

Solutions of the Private Garage Problem

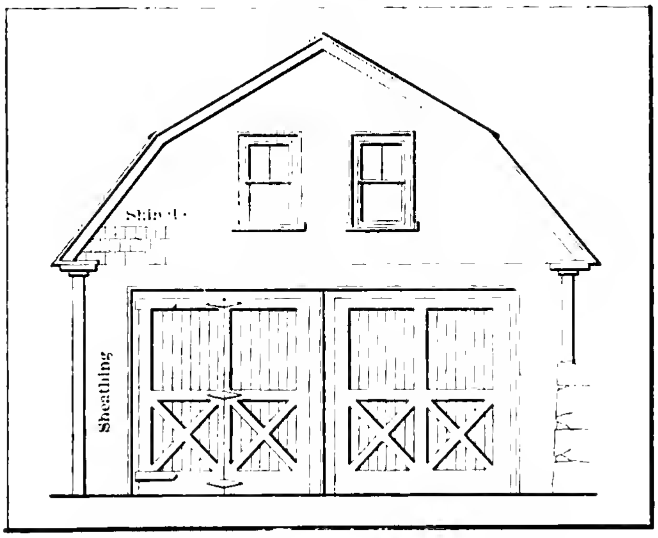
By Morris A. Hall

Part 2

Of All Materials, Concrete Meets with the Most Favor—Two Types of Concrete Garages, One Small, One Large

ONE of the most important reasons why the cost of garages may not be analyzed in detail is because costs are not available. In many cases the cost so overlaps the original estimate upon the basis of which the construction was started that the builder is ashamed to give out the figures. Another reason is that the man starts in to build a very modest structure, to cost very little. The addition of this feature and that feature so adds to the size or scope that extension is necessary, and again the cost is exceeded. In many cases the owner and amateur builder forgot some very important part in the original plans, necessitating redrawing the plans and altering the building. This, through shame or otherwise, causes the cost to be suppressed. Then others withhold figures on the assumption that it is no one's business but their own. This mistaken notion has done much to hold back the universal construction of the ever-necessary private motor house or garage.

Some few costs are available, and these will be given, preparatory to taking up the subject of the various forms of construction. Thus, the small frame garage shown elsewhere on this page was built from the design of a Massachusetts doctor, who also let the job out by the day and superintended the construction himself. This would require an amount of time which the ordinary man could not give to it, and in considering the figures this should be taken into account. The reason why this must be considered is that, with all due respect for the ordinary laborer and other workmen, more work is obtained in any given time through personal supervision than in any other way.



Front Elevation of Doctor's Garage Built for $500

Garage Large Enough for Two Cars—Less Than $500—So, in thinking over the figures and applying them to your own case, if you cannot oversee the job yourself, add something to the cost as given. This garage was intended for but one car, although it was made very large, 20 by 28, which again influences the cost through the amount of material needed. In addition to the large size of the house, a very large cement washing platform was built outside of the house, in front of it, in fact, and upon this all washing was done, in fair weather at least. This also added to the cost. The material and cost was as follows:

Material or Work	Cost
Lumber and Carpenter	$398.63
Foundation	12.00
Blinds	6.60
Drain Pipe and Hardware	8.90
Sink Piping and Work	14.87
Cement and Laying	16.50
Painting Foundation, etc.	7.50
Painting (Estimated)	25.00
Total Cost of Garage	$490.00

An inspection of these figures shows that the largest item of all is lumber and labor of erecting the same, this amounting to over 81 per cent. of the total. From this it is apparent that if the cost is to be reduced materially the size of the house must be cut down. The cement washing stand in front of the structure could not have influenced the cost to any great extent, as even considering it to have an area equal to that of the interior, so as to be equivalent to half of the whole cement work, eliminating the same would only halve the cost, or take away $8.25. It would appear, upon giving the matter a little thought, that the above assumptions could not hold true, so that the most that one might save in this direction would probably be $7. Again, one might say that blinds were unnecessary in a garage, but cutting them out reduces the cost by only $6.60, which, added to the other saving, totals but $13.60. As this is but 2.5 per cent. of the total, we are forced to repeat the first statement, that to reduce the cost of this garage it will be necessary to reduce its size, the saving as per blinds and cement platform being less, much less, than those two features are worth.

As was stated, this garage is plenty large enough for two cars, and a person liking the layout, but being economically inclined, either from preference or choice, might like to figure what one similar to this, but of a size to accommodate but one car, would cost on the basis of the above figures.

So, the cost above has been very carefully figured over on the assumption of cutting the size down to 14 by 20, that is, as wide as this one was, but having only half the length. Figured over on that basis, it would appear as if the maximum amount to be saved would be about $150, which would reduce the whole cost as above to $340.

This, then, forces one to the conclusion that a garage to be low in price must be very small, and as near to the size of the car as is possible. This is a conclusion which is not very pleasant, and so it is a source of gratification to be able to give some figures on another garage, in the construction of which space was used freely, resulting in a very large garage, even larger than the one just described. Despite this fact, the whole cost was less.

What One Doctor Accomplished—As shown on this page, it is rather spread out, but, as will be explained later on, this was due more to its method of construction than anything else. Like the first, it is located in Massachusetts, and, like the first, also, much of the work was done under the supervision of the owner. More than that, the rest of the work he did himself at odd times. In this way the construction was extended over a long period of time. To offset this, the money saved was very considerable, and the work itself was well worth while, as it provided both exercise and recreation. Moreover, as will be brought out later on, this method of construction allowed the addition of numerous little conveniences which cost but the price of a plank and a few nails, practically nothing. But with a carpenter doing the work, even these very small items assume a large proportion, and figure prominently in the final cost.

The resulting garage incorporates two old buildings, an old carriage house at the left (upon which are placed the reference letters A, T, J, J, S, K and G), as well as a hen house and hen yard (lettered M and L, respectively). To the right of the old barn was built a lean-to, which added 286 feet of floor space, being 26 feet long by 11 feet wide. The size of the original carriage shed was 15 feet wide by 26 feet long and 9 feet high. This gave a floor space of 390 square feet, the total being just under 680 square feet. Some of the costs are approximate, as they were made up afterwards from memory, but in the main the figures are reliable. The whole cost was divided as follows:

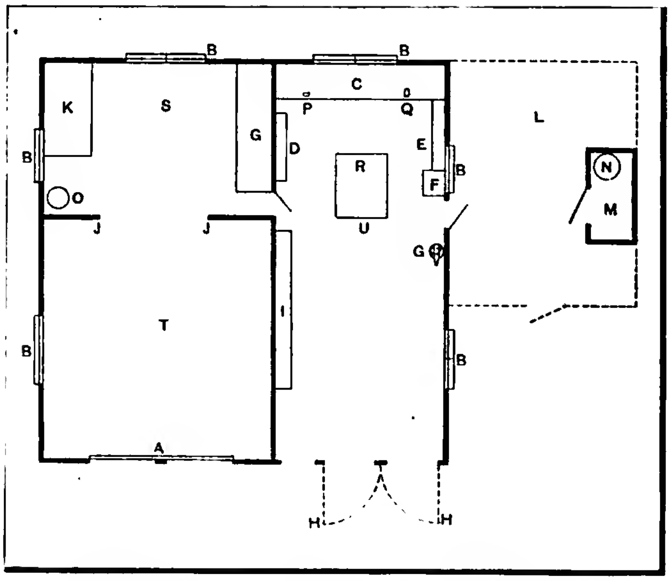
Material Only	Cost
Original Shed	$100.00
Cement Floor for same	30.00
Lean-to, including Cement Floor	110.00
Partitions, Benches, Lockers, Shelves, Pit, Etc.	25.00
Hot Water Heating, Incidentals	26.00
Total Cost	$290.00

Since the details are of more interest than the exterior features or the plain facts of cost, it will be well to describe the whole interior arrangement, referring to the letters on the floor plan. The letter A at the front represents a pair of rolling doors, one rolling past the other. This arrangement, coupled with the size of the doors themselves, gives easy access to the room, and plenty of light to work there once the car is inside. The interior lighting is much improved by the two large windows B, B, facing the south. One of the doors carries a large pane of glass (it could hardly be called a window), which adds to the interior light when it is necessary, owing to weather conditions, to keep the big doors closed. T is the space where the car stands normally, and this is separated from the space S back of it by means of the rolling doors J, J. These make the space S into another room and add to the convenience in many ways. This latter is a sort of living room, in that it has a bunk, K, in the corner, which is used by the chauffeur who may be kept waiting for a long time, or upon other occasions. This is not stationary in the ordinary sense of the word, but may be folded up against the wall and out of the way when not in use.

As located, it is close to the hot water heater, O, which furnishes the heat for the whole structure, pipes running through into the lean-to and heating that. The size of the heater was carefully selected so as to use the smallest one that would heat the two buildings comfortably. In this way the fuel consumption is kept low.

That this room is not a resting place pure and simple is shown by the presence of the anvil, G, in the opposite corner. This is very handy for straightening out bent parts, as well as doing small and simple forging jobs. In the latter case, the heater is used as a fire, so the usual smith's fire is not necessary.

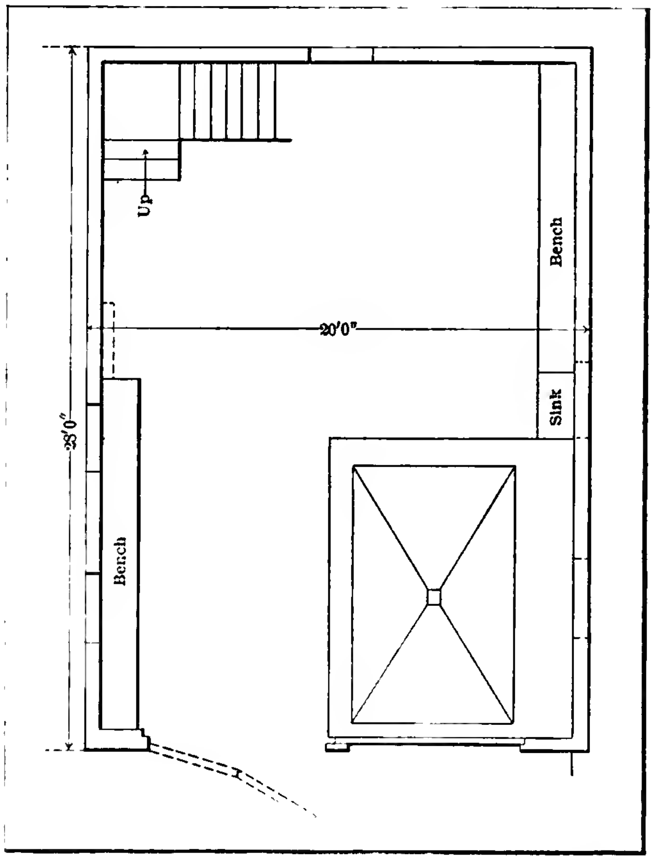
L represents the space formerly occupied by the hen yard, and M the hen house. The latter has been converted into a



Another Doctor Built This From an Old Barn for $300

gasoline storage shed by the simple process of cleaning it out, and installing a large tank. This has a capacity of 100 gallons, and by buying the fuel in such large quantities a rather noticeabl· saving is effected, so that the old hen house serves a double purpose. This tank has a faucet which can only be opened by means of a key, while the house itself is always kept locked. Beyond these two precautions the house is enclosed by a five-foot fence, so that to get into it and get gasoline would be quite a task, more so than the value of the fuel would warrant.

No Danger from Fuel Being Near Fire—To insure that the gasoline never approaches the fire very closely, the room in which the latter is located is so constructed as to be shut off from the other room, U, into which the fuel might be brought. R is a pit 3 feet wide, 4 feet long and 3 1-2 feet deep, with brick walls



Plan of Garage Shown on Page 720. Note Washing Platform

Concrete Garage Built in Connection with a Large Residence

and cement floors. In stocking the whole house the owner was not sure that he would be able to do much of any repair work himself, so did not get any tools, but as time progressed and he found time, inclination and ability to make his own repairs, he made a practice of noting down a particular tool which would be useful. Then, upon the next trip to town (some distance away), this tool was purchased. In that way a large stock of useful tools was accumulated without incurring any large immediate expense. Strictly aside from the expense, only the tools known to be of immediate use were purchased, and no money was wasted.

Carrying the greatest weight in the whole erection of the building, its outfitting and subsequent use was the idea of getting all that was possible out of every dollar expended. The owner's personal ideas relative to the private garage are best expressed in his own words. He says, in part:

"During the past five years my garage has more than paid for itself by saving me large sums in repair bills. You have a place to do the work, and the supplies are on hand, so that you attend to your repairs as soon as needed rather than wait until a larger expenditure is needed. You have no storage bills; you pay the repair man for actual time spent on your work, rather than paying for all the time the car is in the shop, whether they are working on it or not (this the writer had to do before he built his garage). Cars are handled much more carefully in a private garage than in a public one, and there is no chance of things being stolen. Tools can be bought as you find you need them, and in that way you will get just what you need, and buying them a few at a time will not feel the cost."

Very Marked Influence of Size of Car—It is immediately apparent from a consideration of the above figures of actual buildings that the size of the car exerts a large influence upon the cost of the garage. Since the wheelbase of the car determines the length of the whole car, it will be interesting to look into the matter of wheelbases and overall lengths.

Data on this subject is very scarce, as the extreme overall dimension is one that is seldom required except in shipping a car, so that this is not very often measured. One of the leading manufacturers compiled such a table several years ago. This only includes the cars built by this firm, but it must be taken as an average value. Moreover, in the scarcity of similar figures, even this has value, for the heights and lengths with top are given.

Table Showing Principal Dimensions of Typical Modern Cars

H.P.	Type Remarks	Wheelbase Ft.	Wheelbase In.	Length Ft.	Length In.	Width Ft.	Width In.	Height Ft.	Height In.
14-16	side entrance	8	4	12	6	5	2	5	3
14-16	side entrance (hood up)	8	4	12	6	5	2	7	5

40	limousine	10	4	14	4	6	0	7	8

N.B.—In some cases the lamps mean a further increase in length.

From these figures it is possible to deduce the fact that the average additive quantity which the car projects beyond the centers of the wheels is 4 feet 4 1-2 inches. Taking this at 4 feet 6 inches, it is possible to compute the overall length of any car.

As throwing some light upon the garage problem in an indirect way the table given in THE AUTOMOBILE last winter in connection with the New York show issue has been gone over. From this the average wheelbase in each class has been figured.

For the cars classified between $1,000 and less, 17 different ones average 91-inch, or 7-feet 7-inch wheelbase. In the next class, $1,000 to $1,500, the wheelbase averaged from 19 cars increases to 106 inch, or 8 feet 10 inches. In the $1,500 class, that is from that figure up to $2,000, the average of 24 cars yielded a result of 110 inches or 9 feet 2 inches. Continuing the steady increase, the class of cars selling at from $2,000 to $3,000 yields the figure 114 inches, or 9 feet 6 inches. In the next class, $3,000 up to $4,000, a total of 26 cars averaged 118 inches, or 9 feet 10 inches. The $4,000 to $5,000 class yields a length of 124 inches, or 10 feet 4 inches. In the $5,000 upward division, 128 inches, or 10 feet 8 inches, result. Applying to these the additive quantity, namely 4 feet 6 inches, the overall length for these averages becomes: $1,000 and less class, 12 feet 1 inch; $1,000 to $1,500, 13 feet 4 inches; $1,500 to $2,000, 13 feet 8 inches; $2,000 to $3,000, 14 feet; $3,000 to $4,000, 14 feet 4 inches; $4,000 to $5,000, 14 feet 10 inches; above $5,000 15 feet 2 inches.

In applying these figures to the design or construction of a motor house or private garage, the owner of the car should add to the overall car size such an amount as his personality and attitude toward the economy question would dictate.

Suburban Lots Allow Floral Effects Which Enhance Appearance of Frame Garages

How The Power of an Old Engine was Increased

By Oliver Light

FROM the first crude internal combustion engine, developed by Gottlieb Daimler nearly a quarter of a century ago, to the present, efficient, and highly specialized form, has been a huge advance, marked by slow and very gradual steps.

The principles entering into the consideration of the design and construction of the efficient motor were not as well known to early engineers as they are at present, and, as a result, their productions, while practical and efficient for the time, make but a poor showing when compared to our modern forms. It was found by early designers that theory was one thing and its practical application another, and in many cases it was difficult to reconcile them in practice or to explain the results obtained. In contrast, at the present time, the general principles which govern design (thanks to the information presented in the trade papers and more experience) are well understood by engineers, and many laymen have more than a rudimentary knowledge of the gas engine.

As an example of what may be accomplished by an intelligent application of principles, the writer proposes to describe a change which was made on an engine designed nearly a decade ago which change increased the power produced by 50 per cent more than previously obtained, this without any change in piston displacement and in a simple and practical manner.

Minor Details Held Old Motors Back—Many of the earlier motors when contrasted to present forms have not proved satisfactory because of some minor detail or part which had not been properly considered by the designer, and the point on which they most often erred was undoubtedly in valve proportions and location. Modern engineers have learned that valve placing and size have a material bearing upan the efficiency of the internal combustion motor. The fundamental consideration often overlooked is that the gas be admitted to the cylinder as quickly as possible. Also, after it is burnt, the inert products of combustion which can serve no useful purpose after the first expansion during the power producing stroke should be expelled promptly, and with minimum back pressure.

Back pressure results in the retention of useless gas in the cylinder which means that the quantity of fresh gas taken in will be reduced and its quality impaired by dilution with the non-combustible residue. Reduction of back pressure is important in all kinds of expansion engines, and on some the efficiency will be seriously impaired if there is any resistance to the prompt expulsion of the inert products of combustion. It is not only important that the cylinder be cleared promptly, but the fresh gas must be given every opportunity to fill it to full capacity.

Valve sizes have a material bearing upon the rotative speed of the engine, and recent experiments and racing experience has shown that some methods of valve placing enable the designer to use larger valves and give higher efficiency than do some other positions. While speed of rotation is an important factor in determining the power output of an internal combustion motor, it is not the only consideration nor the only advantage which large valves have over smaller ones. Prompt charging of the cylinder and rapid expulsion of the gas, made possible by the use of large valves, also results in increased flexibility and improves the "pulling" qualities at low speeds.

The writer has from the first held rigidly to certain tenets, one of these being that valves should be located directly in the head so that the opening would lead to the combustion chamber without pockets to retain heat or prevent free gas flow, another being that the valve diameter should be as near half the cylinder bore as the design would permit.

Description of Car and Engine Experimented Upon—An associate of the writer owns a small runabout of well-known make and somewhat ancient pattern, of which many thousands have been sold in past years. The motor employed is of the single cylinder type, 4 1-2 inches bore and 6 inches stroke. The cylinder head is a separate casting, being attached to the cylinder by means of studs, a packed joint insuring both the retention of compression and cooling water. The appearance and details of construction are clearly shown at Figs. 1, 2 and 3, and the sectional line view presented herewith, and will be easily recognized by automobile mechanics the world over, who will undoubtedly have fond(?) recollections of the difficulties met with in making a packing hold which would be both water and gas tight.

In this head, the valves are vertically disposed and actuated by peculiarly shaped rocker arms which in turn were lifted or depressed by the action of a cam upon the rollers at their outer ends. The valves were but 1 1-8 inches in diameter with about 3-8 inch lift, and the speed of such engine was low, rarely exceeding 850 revolutions per minute, at which they were rated at 4 1-2 horsepower. As will be evident, while eminently satisfactory at the time of their general production and sale, after several years development of multi-cylinder forms which have greater speed and hill climbing ability, their somewhat limited power in proportion to weight took away much of the pleasure of driving them. The low speed was often needed, even on minor gradients of barely ten per cent which other cars surmounted with ease.

While they lacked power, they were well made and have proved more than ordinarily enduring and capable of withstanding abuse and wear and tear of constant operation. Economical maintenance, simplicity of mechanism, and method of operation combined to make them very popular, and thousands were manufactured and sold at a very reasonable price. My friend, who is a mechanical engineer with some experience on gas engine work, was in every way satisfied with his car which had been remodelled and brought up to date in looks, at least, except that it lacked power, and, as must be evident, the little that was originally obtained when the engine was new did not augment with age and wear of components.

Experiments were made with the valve timing and some improvement was noted when a new cam, keeping the valves full open for a longer time, was fitted. Later, an accident made the replacement of the head necessary, and then opportunity was obtained to try an experiment which was interesting, and which improved the capacity of the engine almost beyond belief. In order that the change made may be followed intelligently by those who have not had experience with this make of car, a brief description of the old head and method of valve operation is necessary.

What the Old Cylinder Head Was Like—Fig. 1 shows a three-quarter view of the cylinder head, showing the exhaust valve and port, as well as the operating levers. Figs. 2 shows the inside or front of the head, making clear the limited port area leading into the cylinder from the combustion or valve chamber, also the small space between the stud holes and the inside flange, as well as the small amount of metal outside of the water passages, making it almost impossible to make a packing which would be enduring and satisfactory. The head was partly water-cooled in that the valve chamber was surrounded by water spaces. Fig. 3 shows a direct back view, making clear the placing of the valves and operating levers. The hole immediately under the exhaust valve lift is the cam shaft bearing, this shaft running along the side of the engine and parallel with it,

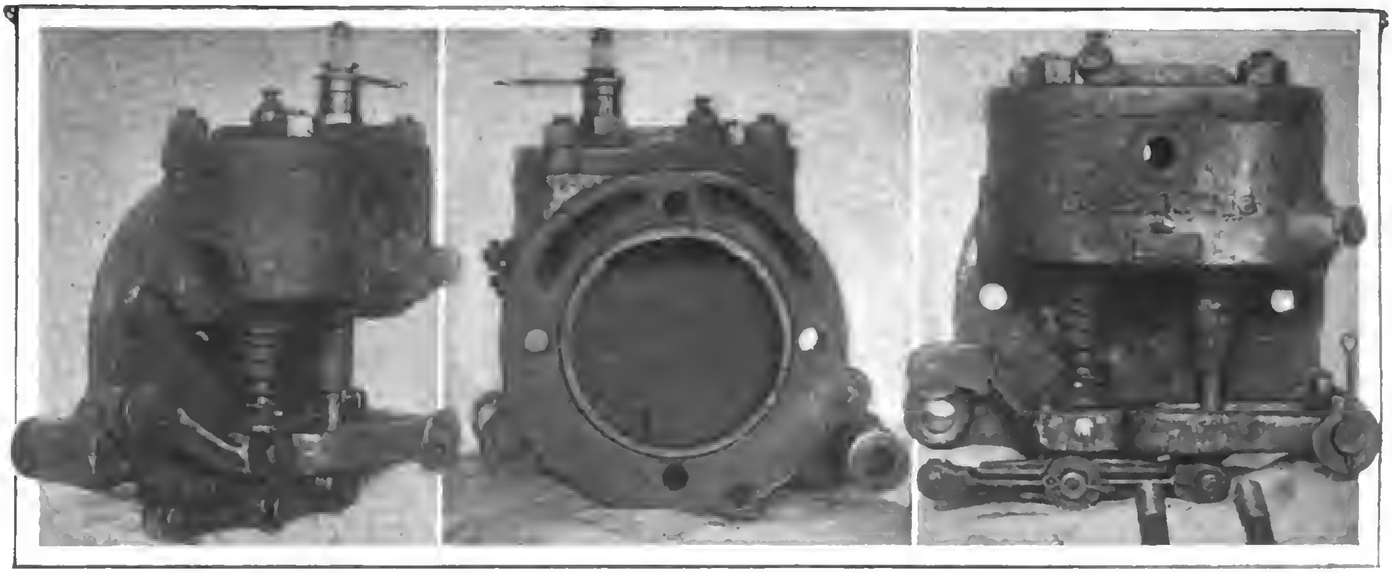

Fig. 1—Three-quarter view of old head Fig. 2—Front end, showing small passages Fig. 3—Another view of the old head

being driven from the crankshaft by a pair of exposed worm gears which gave the required reduction in speed.

In the exhaust valve seating a crack developed, a not uncommon occurrence with this form of engine design, in which part of the head was cooled by water, the remainder by air, probably owing to uneven cooling and poor distribution of metal. This opening penetrated the water space, and not only was the compression destroyed after the head had become slightly heated, but water was admitted to the cylinder as well. The effect of this upon engine efficiency can be imagined.

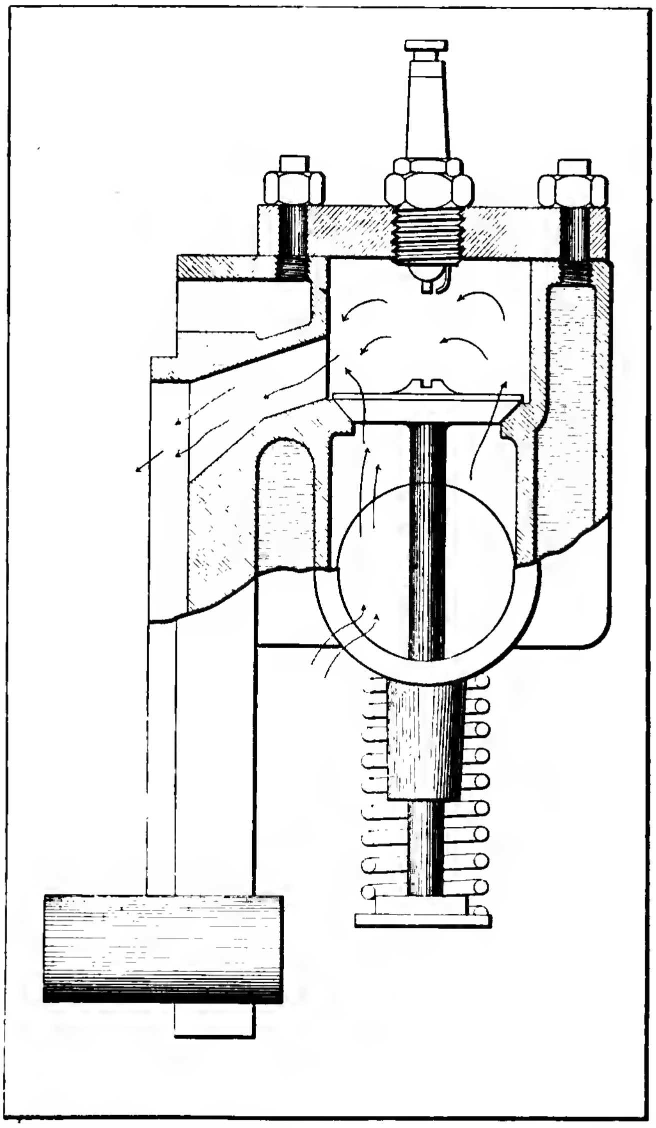

Fig. 4—Sectional arrangement of old cylinder head and passages

Upon investigation it was found that a new member would cost $25, and as restoration of the old head was not possible it was decided to scrap it, and instead of ordering a new component of similar design from a factory several thousand miles away, it was decided to try the effect of larger valves and more advantageous placing by designing a new head which would go in place of the old one without too much change. This was made possible by the detachable construction of the defective member.

Latent Possibilities of the Old Engine—As the writer had long been of the opinion that many of the old engines could be made more serviceable and efficient by refinement of detail or the incorporation of up-to-date features, and as this was shared by the owner of the car, a new type of head was evolved and applied to prove our pet theories. In designing this member. there were several considerations which made it necessary to proceed carefully. Among these low cost, simplicity and interchangeability with the old pattern were important considerations A more efficient and doubtless more satisfactory construction could have been designed than the form finally selected, but it is doubtful if this could have been done without expensive alterations. In the first place, it was found that the cost of a water jacketed head pattern was more than one would feel justified in expending when it was considered that but one casting was to be made. Detachable valve cages and large valves involved machine work and more costly patterns, as well as making it difficult to operate the valves from the old camshaft.

After a number of forms had been proposed the type shown at Figs. 5, 6 and 7 was selected. As so large a part of the old member was not cooled by water, without any overheating having been manifest, and because of the greater simplicity and lower cost of the pattern, an air-cooled head was made in which the valves seated directly, the detachable construction making it easy to remove same should the valves need grinding. It was found that if the valves were placed at the top of the head, as shown, that there would be no difficulty in operating them, and no changes in muffler or intake piping would be necessary.

As will be seen, fairly large valves were employed, directly actuated in a manner that was simple and mechanical. These members were made 1 1-2 inch clear opening, the valves themselves being about 1 3-4 inches in diameter, of the conventional bevel seat type. The lift was 3-8 inch, as in the old head. A comparison between Figs. 4 and 8 will serve to show the difference in size of valves, as well as the improved method of charging the cylinder or allowing the old gas to escape. In the old head not only were the valves of insufficient diameter, but the gas flow was retarded by the devious passages through which they gained access to the cylinder or to the muffler, as the case might be.

Sharp Bends Reduced Amount of Charge, and Consequently, Power—Several sharp bends prevented prompt charging or expulsion, and except at low speeds it was difficult to properly fill or clear the cylinder. For this reason the motor was slow running, and developed but little power when in the best of condition. It will be evident from an inspection of the sketch of the old head that there was a large portion that was not water-jacketed.

In making the new head, it was thought that the better clearing of the cylinder because of the valve placing would make the use of a water jacket at this point unnecessary, and this has been borne out by practical experience with the new construction. The gas entrance is direct into the cylinder, there being but one bend or corner for the gas to flow around, either in coming into or going out of the cylinder. The irregularly shaped combustion chamber has been dispensed with, the inside of the head being clean and smooth, there being no sharp corners to retain the heat or cause trouble otherwise.

While the compression has been raised to some extent by cutting out the pocket, because of the better opportunity offered by the larger valves for prompt cylinder clearing, absolutely no difficulty has been met with in cooling. Runs of fifty miles have failed to heat up the head sufficiently to cause premature ignition. The head gets hot, as is natural, but does not attain a high enough temperature to show the slightest color when examined after a hard run at night. The exhaust pipe is red hot, but the exhaust valve chamber does not show that it is unduly heated. The inlet side of the head has not even become discolored, the valve chamber, which is not provided with flanges, not having heated enough to burn off the graphite paint with which the head was daubed after machining, and this after over 500 miles of running. The new member went right into place without trouble, the only change that was necessary was the removal of two short studs and the substitution of longer ones, because they passed through the valve chamber, the old ones not being long enough.

Fig. 5 is a three-quarter view of the new member, showing the method of valve placing, the flanges on the exhaust valve chamber, the bevel gears used to drive the short auxiliary camshaft carried on the cylinder head, and the bronze tappet levers or walking beams which actuate the valves. As will be evident, a large roller is fitted at the lower end of each tappet, this bearing directly upon the cam, carried by the short shaft. Threaded plugs are used at the upper end as a means of adjustment of clearance between the valve spring retaining collar at the end of the valve stem and the tappet.

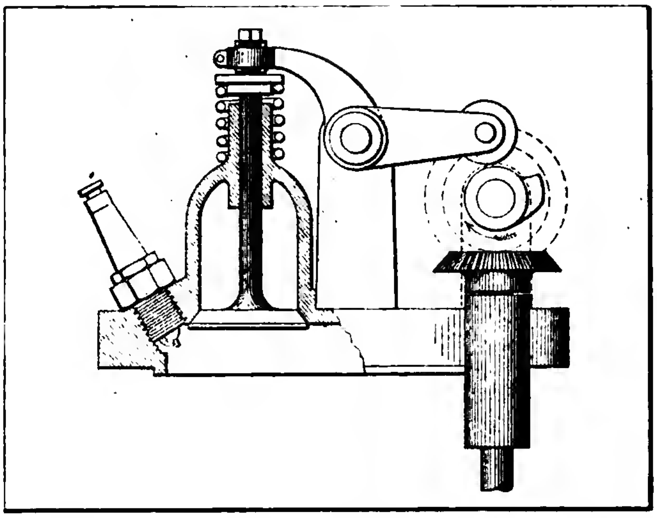

Fig. 8—Method of operation of new valves through rocker arms

The rocker arms are fulcrumed at the center, and operate upon a short stud supported by a suitable lug cast integral with the head. Fig. 6 shows the front or inside view of the new member, the valve to the left being the inlet, the other the exhaust, while the spark plug hole is shown directly above and between them. The spark plug placing is advantageous, as the spark takes place directly in the cylinder, which should be an improvement over the method employed in the old head, where the gas in the combustion chamber was first ignited, after which the charge in the cylinder was fired by the flame shooting through the port into the cylinder.

New Spark Plug Location Fires Charge Quicker—With the new method of placing, flame propogation is undoubtedly more rapid, and better results would be obtained at higher engine speeds than with the old method of igniting the charge. Objection may be made that the placing of the spark plug in an uncooled mass of metal would be extremely hard upon the insulation, but it should be remembered that even with the old head the spark plug was placed in an uncooled plate which served as a cover to the valve chamber, and but little trouble was experienced with it.

In the direct back view, Fig. 7, is shown clearly the design of the head. The auxiliary cam shaft is carried by a pair of lugs

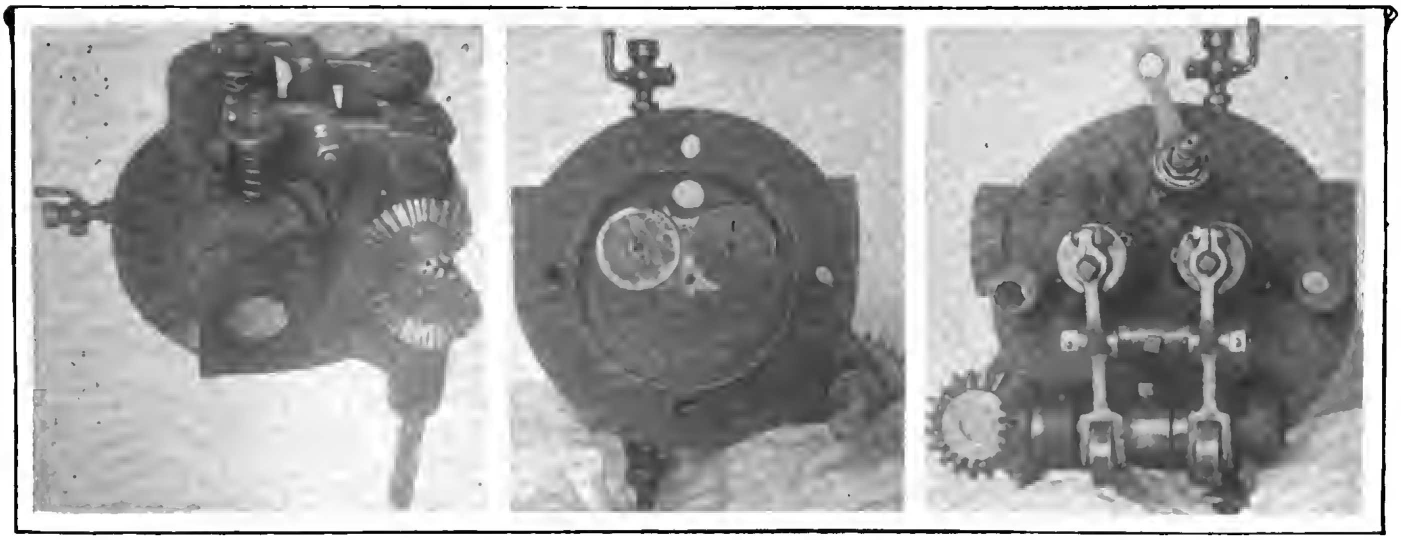

Fig. 5—Three-quarter view of new head Fig. 6—Inside showing size of valves Fig. 7—New head showing mechanism

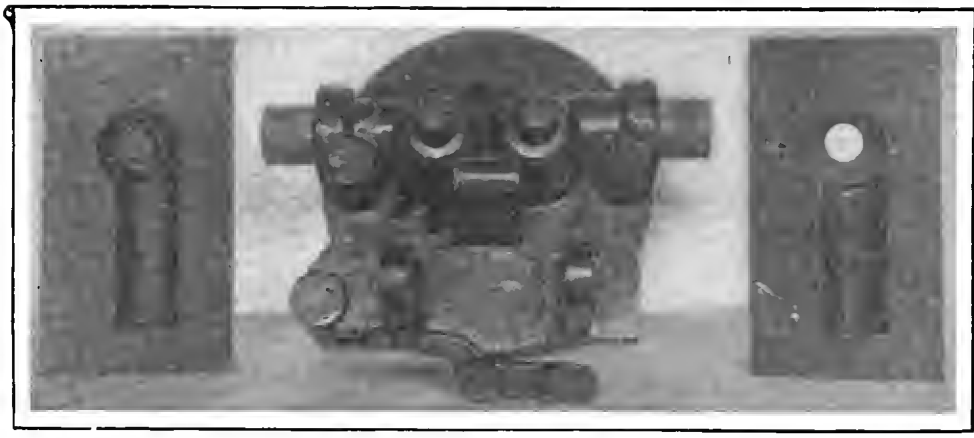

Fig. 9—Pattern of cylinder head and core boxes for valve cages used in making the change

which are bronze bushed and which are cast integral with the head, while the tappets or rocker arms are supported by a large bolt passing through a central lug. The spark plug placing and the valve chamber construction is clearly shown. At the top is placed a compression relief and priming cock, while at the bottom of the head a pet cock for draining out the accumulations of oil (which invariably collect in the bottom of the combustion chamber of a horizontal cylinder) is fitted. While in this view the cams are seen attached to the shaft by set screws, this was only temporary means of fastening during timing, they being permanently fastened by taper pins. In order to show the appearance of the head casting before machining, at Fig. 9 is shown the pattern from which the head was cast, as well as the halves of the core box for the valve chambers. The smaller pattern in the immediate foreground is that of the rocker arms, which for convenience were made bronze castings.

Through the use of the new head, the change in engine operation obtained is remarkable, and that power has been increased, admits of no controversy. The little car, which weighs over 1,100 pounds, and which is geared but a little over 3 to 1, will climb a 20 per cent grade on the high speed without a falter, pulling excellently at low speeds, and answering the throttle with a responsiveness usually associated only with multiple cylinder engines. The speed of the engine has been increased as well, and the car can speed well above the legal limit of 20 miles per hour.

Around the cylinder a water jacket is still used; and absolutely no trouble has resulted from overheating of the head. It was advanced by some before the change was made that the engine would never work satisfactorily under the conditions imposed by an air-cooled head because the valves would warp and fail to hold compression, and again, the head itself would become distorted by the high temperature to which it was subjected. While not as clean a piece of designing as the writer's associate is usually credited with, the distribution of metal was more uniform that the irregular outline of the head would indicate, and compression is as good after the engine has become heated as when first started, a little better if anything. The head answers the purpose and has served to make a very able car, which asks no odds of any other single cylinder, out of an old model which never had sufficient power even when new.

Amount of Power and Speed Increase—The larger valves and improved placing have made possible an increase of engine speed of 400 revolutions per minute. and the surmounting of a good 20 per cent grade on the high speed, which was not taken on the low any too easily with the old head, is evidence enough that the power has been increased by a substantial margin. This experiment has served to prove clearly that large valves, combined with a location directly over the piston will give one all the power that is possible to obtain by burning an amount of gas determined by the cubical contents of the cylinder.

The valve mechanism is not noisy, nor has any undue wear been noticed. The exhaust and inlet cams have been shaped so as to give a gradual opening, a long period of full opening and a rapid closing, and the original timing as determined by the flywheel marks has been adhered to. The exhaust valve opens about 40 degrees (crank travel) before the end of the expansion or power stroke and closes about 10 degrees past the top of the expulsion stroke. The inlet valve opens 20 degrees past the beginning of the suction stroke and closes about 15 degrees beyond the commencement of the compression stroke, or past dead center.

One trouble which the air-cooled head has entirely eliminated is the replacement of packings between the head and cylinder. As will be evident by referring to Fig. 6, a good bearing is obtained for a packing, there being plenty of metal between the edges of the stud holes and the head. The elimination of water passages has removed another weakness of the old design. In making a packing, a piece of well softened Mobiline was placed between two pieces of thin copper, about .005 thick, held together by turning in little lips which had been left on the inner and outer peripheries of one of the pieces when it was cut out of the sheet. This makes a packing which will hold compression with ease, and which serves to prevent water leaking from the cylinder jacket. The sheet packing is preserved because it is insulated from the direct heat and from the hot water flowing around the cylinder by the thin pieces of copper.

Various parts are easily reached, spark plug can be changed without trouble. The valve springs are out in the air and the temper of the springs is not lost as there is every opportunity for free air circulation around them. No change was made in piping, muffler or carbureter placing. The short auxiliary cam shaft and bevel driving gears are not liable to give trouble. Lubrication of components is not difficult, as a little graphite is mixed with the oil, which remains on the bearings after the head has become sufficiently hot to vaporize the fluid, and even the exhaust valve stem is coated with a thin film of graphite at all times. The valves have been made especially strong at the head, and no warping has been noticed or has grinding in the seatings been necessary, proving that there has been no distortion.

OPPORTUNE COLD WEATHER PRECAUTION

A large number of motorists who store their cars away for the winter do not take proper care of their tires. According to the Fisk Rubber Company, a good many tires are allowed to deteriorate in this way, and when the cars are put into commission again in the spring, the casings do not give the service that they should.

When a car is laid away for the cold months, the wheels should be jacked up and the tires deflated. It is essential that they should be kept in a place where no sunlight can penetrate; a cool dark place being preferable. The company advises owners of Fisk tires to examine their rims and cleanse them of any rust, which of course necessitates the removal of the tires, following which a little graphite should be applied to the rims before replacing the tires.

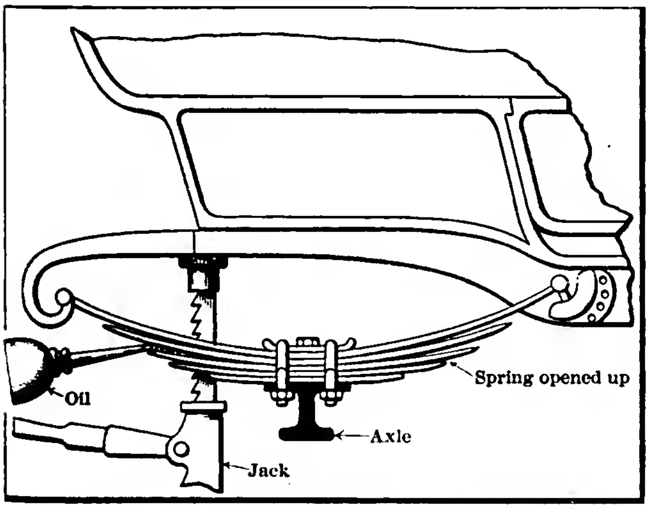
A little attention to spare casings and tubes before putting them away will mean added service in many cases. If there are any cuts in the shoes, they should be filled with a good cement and if there are any spots where the fabric is exposed, it should be seen to that these are perfectly dry.

By far the best plan, when the car is to be withdrawn completely from service, is to remove the tires and lay them away in a closet. They may to advantage be wrapped in burlaps. These precautions will insure their good condition in the spring.

GOOD SPRING ACTION DEPENDS UPON CARE

LIFE in springs will be prolonged if they are properly lubricated, since, *a*, rust will be aborted, and when springs are allowed to rust up the pitting which follows marks the point of failure, simply because the rust indentation has the same effect as a notch which is made in a test proof to make it fracture easier and to mark the point of rupture; *b*, real (desired) spring action will follow, and unequal strains will not take place. Take half-elliptic springs for illustration; they are made up of a plurality of flat leaves, each shorter than the other, all of the same width, and all given a bow so contrived that the extreme fiber strain will be the same in each plate when the spring is deformed under the load it is designed to carry.

The reasons for using several plates is to limit the extreme fiber strain, considering a given span of the plates, and a given action in the transverse plane, as well as to absorb energy and put a quietus on the motion of the body. It would be possible to use a spring made of one plate only were the same tapered from the center out in such a way as to afford such limber qualities as the word implies; the amount of energy the spring so made would absorb would depend upon the amount of molecular work engendered, and the spring would reach the end of its kinetic life the sooner simply because all the energy that could be absorbed would be in the form of molecular work.



Illustrating Method of Lubricating Plates of Spring

Spring makers understand the necessity of long life, knowing full well that molecular work, unaided, would not represent enough loss of power, as it were, and they hit upon the happy expedient which resulted in the use of a laminæ of flat plates, each one shorter than the other, and all of them so thin that the extreme fiber strain would be limited to a safe point, taking into account kinetic life rather than rupture under the incidental load of the moment. In this scheme, in order to increase the power absorption, the plates are made to press against each other with a considerable force, and since in action there is relative motion of the plates, friction is set up between them.

The amount of friction see up depends upon the pressure on each unit of surface of the respective leaves, and, as will be readily understood, the plates must lay against each other at all points to afford the maximum result. This condition will obtain if all the plates are bowed to the same radius, irrespective of lengths, and pressure will then be considerable, while the extreme fiber strain will be the same in each plate, irrespective of the length, so that the kinetic life of the respective plates will be the same.

The amount of energy which can be dissipated by friction alone, which is the property to take advantage of, will be in direct proportion to pressure and the surface offered between pressing plates, and it follows that the greater the number of plates, the greater will be the energy dissipated. If a large number of plates are used, each one of them may be relatively thin, and the extreme fiber strain will then be a minimum, which is a guarantee of kinetic life and another way for saying the springs will last for a long time.

Lubrication Is Necessary to Engender Easy Action—When springs are properly made, the plates press on each other with sufficient force to cause them to seize, and the action will then be "fierce." At the instant of seizing the local strains set up in the fiber of the plates is enough to cause rupture in many cases, and the only way to abort this very undesired performance is to lubricate the spring, which to do requires that it be relieved of its load, when it will return to its open position in the manner as shown in the figure. If all the plates are bowed to a common radius, since each one is different in length from the other, the ends will open up just as the figure shows, and an oilcan may then be used to squirt oil on the plates forming the laminæ.

Since spring-plates are rolled with a concave surface, so that there is room for the oil between them, and in conformity with the behavior of the lubricating oil, it will tend to stay on the plates, rather than to be squeezed out, since it will flow to the center, away from high levels, when it is heated or put under pressure. An acid-free mineral oil, such as is used in cylinders of motors, is suitable for the purpose for reasons as follows: (a) It will not gum or evaporate; (b) it will not etch the material; (c) it will afford the requisite lubricating properties.

Long life, when flat plate springs are considered, would seem to be due to the use of very wide, thin plates, rather than relatively narrow, thick plates. Makers of springs sell them on a pound basis, and the thicker the plates, the lower will be the price, simply because the number of plates which will have to be handled per hundred-weight will be lowered as the thickness is increased. Matters of this sort, while they involve the commercial side of the situation, have to be taken into account when users of cars are trying to get all they can out of the springs. Retainers, if they are properly placed, will help out marvelously, especially if the plates are thick and a limited number of them are used. It might look as if lubrication is not desirable under such conditions, but it is only necessary to remember how fiercely a clutch will behave if the lubrication is awry, and how well the same clutch will pick up and hold its load when attention is given to the lubrication. It is the same problem; the clutch refuses to work properly when the metal contacts and seizes, and the springs act in precisely the same way.

PISTON VELOCITY IS NOT CONSTANT

The ratio of connecting rod length to stroke influences the velocity of the piston, and the following will hold:

Let,

l = eccentricity of crank (half the stroke).
L = length of connecting rod.
v = linear velocity of crank-pin.
θ = crank angle.
S = piston velocity in feet per minute.
r = ratio

when,

$$r = \frac{l}{L}$$

and,

$$S = v\ (\sin \theta \times 1|2\ a \sin 2\ \theta).$$

In the above expression for the piston velocity, all terms higher than $2\ \theta$ are neglected because of their small value, which affects the result so little, and only makes the formula more and more cumbersome.

REPAIRING CYLINDERS

Editor THE AUTOMOBILE:

[2,065]—Is it possible to repair a small crack in the top of the water jacket of a horizontal cylinder (caused by freezing) by the use of some preparation made for that purpose? And if so, what is it, and where is it obtained?

Why are some cars made with only 55-inch tread? In such cases are not the tires chafed on the inside when driving over country roads?

Where is the Shawmut car, which participated in the New York to Paris race, made? W. N. HEDBACK.

Cumberland, Wis.

Cylinder cracks may be repaired by the use of several cast iron cements, these being applied in the form of a stiff paste. Without mentioning all of them, you probably will recall having seen one of them advertised, namely, Smooth-On. This material would not do for a crack of any size, say larger than 1-8 inch in width, if it could be applied with success for one as large even as that. Since this is in the nature of a temporary repair, it would be advisable to do a better job and have the cylinder brazed. The process of brazing, or at least, welding cast iron has been developed to a very great extent, and there are many places where work of this sort may be done. The expense of sending the casting, having a weld made, and return charges would be far below the cost of a new cylinder, the amount being, of course, dependent upon the size and character of the crack. The company making a cement and located nearest to you in the S. H. Brand Company, Chicago.

In the issue of Oct. 21 of THE AUTOMOBILE you will find something on the subject of various treads, the inquirer there asking why the different ones were used. As far as the chafing action on country roads is concerned, we presume that you have taken it for granted that all wagons have exactly 56 1-2 tread and that all of them run in exactly the same track on the road, so that two very narrow ruts are formed of just that distance apart. This assumption is, however, far from the case. Not all wagons have exactly standard tread, there being a slight difference among them, just as among automobile manufacturers. More than this, the wheels of a huggy or wagon get out of true easily and quicker than do those of an auto. Being out of true, the wheels do not make tracks exactly standard tread distance apart.

Taking a real bad case, let us assume that all buggies are of standard tread. Let us further assume that the tires are not over 1 inch wide, and never over 2 inches out of true. That is, one inch inside of standard and one inch outside. The tracks in the road will then measure 54 inches inside to inside and 58 inches outside to outside, and will be each 3 inches wide.

Now, let us assume the worst possible case for an automobile, namely, the narrowest tread and the smallest tires. Suppose we take 55 inch tread and 3 1-2 inch tires. The inside to inside measurements will be 51 1-2 inches and the outside, 58 1-2. The one wheel will then run in a rut, but the other will not, since the width will not allow it, rather it run on the high part of the road inside of the rut, but overhanging the latter somewhat. Due to the limited actual width of the tire in contact with the road, which in turn is due to the circular shape of the outer part of the tire, this overhang will suffer little if any injury from the road ruts. As we assumed the worst possible case, it seems only fair to conclude that there will be very little tire injury from this cause, the wheels varying more than we assumed on buggies, while the tires run wider than 1 inch. So, it will be the ordinary case that the ruts will be about 4 or more inches wide. Larger tires than 3 1-2 are now the case, and the higher tire-inflation pressures now common have both done much to render this form of tire depreciation very small.

More than this, the much larger tires now used would span the narrow ruts, and not drop into them as you have suggested.

The Shawmut car was built in Stoneham, Mass., but its manufacture has been discontinued for some time. There was talk of reorganizing the company at the time of the successful run across the country in the race you speak of, but to our knowledge, this has not yet been effected.

SMALL ELECTRIC HORN

Editor THE AUTOMOBILE:

[2,066]—Will you please advise me of the name and address of the maker of a small horn run by electricity and similar to the Klaxon, both in principle and sound, except that it sells for $10.00. It is a much smaller horn than the latter, and the sound is more subdued. It makes a very nice horn for city use. A party who toured here from St. Louis had one, and I understood him to say that it was a Klaxon. They deny making anything of the sort, however. The horn I have reference to has a short bell, which flares somewhat, and the working part of the horn is small. It also works with an electric button. As I wish to get one of them, I would appreciate it very much if you will help me. H. M. HALL.

Washington, D. C.

While we cannot help you out in so far as telling you the name of the horn in question, we can be of some assistance to you by giving a list of the makers of electric horns. Taking this list as a basis, you can readily find out which firm makes the horn you wish. The firms making electric horns, aside from the company you mentioned, are as follows:

Elkhart Dry Battery & Signal Co., Elkhart, Ind., Electro-Corno.
Theodore H. Gary Company, New York City, Grack-Unicum.
Holtzer-Cabot Electric Company, Brookline, Mass.
O'Brien Electrophone Company, Hallowell, Me.
Russell Electric Company, Danbury, Conn., Treco.
Sireno Company, New York City, Sireno.
S. Smith & Sons, New York City, Crack.

PHONE MAGNETO IGNITION

Editor THE AUTOMOBILE:

[2,067]—I am a constant reader of "The Automobile" and seem to remember, but can not find, an article on the subject of converting a telephone magneto into one for an automobile; that is, so that it can be used for ignition purposes. Will you please tell me in what issue or number that article can be found? E. B. GARRETT.

Knoxville, Tenn.

While not exactly as you describe it, the matter referred to will be found in the June 17 issue of THE AUTOMOBILE, at the head of the first page of letters, under the head of "Gas Engine Ignition." A man located out West asked about converting a small dynamo into a magneto for the purpose of igniting a gas engine, with which he has had some ignition trouble. Our advice to him in part was as follows: "The ordinary current generator gives too low a voltage and at too high an amperage. If your voltage and amperage were correct, the addition of a spark coil and a timing device would give a spark that would run the engine in a satisfactory manner. The ordinary magneto producing a true low tension current (which is intensified by means of a spark coil) gives about 35 volts at less than one ampere. If this be taken at exactly one to allow of some figures on the subject, the coil output will be, disregarding losses, say 20,000 volts at .15 ampere. This is upon two assumptions, namely, that the dynamo is a direct current machine, and that the field is separately excited, at least for starting. The latter statement is plain, if you consider that for starting purposes with a self-excited machine, a spark sufficient to ignite a charge is practically impossible, because of the very slow speed (comparatively) at which the operator can turn the engine over with the consequent slow speed at which the current would begin to build up. Next, as to the exact time of the spark produced by the outfit, if the engine does not already include such an apparatus, you will have to construct one yourself. To be exact, the current supply must be interrupted just before the point in the stroke at which the spark is desired in the cylinder. This might be done by purchasing an ordinary timer on the market and rigging it up on the machine so that the speed is correct for the engine in question." This might also have been arranged with a homemade timer, if you preferred.

If the above does not help you, or is not what you wanted, write again and let us know. We aim to be of as much assistance to our subscribers as is possible. Questions, in particular for the department of "Letters Interesting, Answered and Discussed," are always welcomed.

ANSWERED AND DISCUSSED

CHANGE IN POWER PLANTS

Editor THE AUTOMOBILE:

[2,068]—Will you please tell me why it is that you do not see many two-cycle engines in automobiles? I have a two-cylinder, four-cycle engine in my car and would like to make a change to a three-cylinder, two-cycle engine. Would you think this change a good one to make? Please answer in the next issue of "The Automobile."

EMIL JIRANEK.

Muskegon, Mich.

As to the relative merits of the two different cycles upon which automobile engines work and the reasons for the popularity or lack of popularity of either one, that has been discussed so many times in these columns, that we do not feel warranted in using the space for a repetition here.

If your idea is to secure better balance, the two-cycle two-cylinder would be superior to the present engine, but if you wish additional power with superior balance, the three-cylinder two-cycle would give it, providing you selected the dimensions of the engines in a proper manner. The balance of a three-cylinder two-cycle motor should be as near perfect as a six-cylinder four-cycle engine, which is universally considered to have the best balance of any engine now built or possible to build.

It has long been the idea among automobile builders that perfect balance or an approximate approach to it, was a necessity, but it would appear as if the success of aeronauts abroad with engines which were badly out of balance must lead to a revision of our ideas on the subject of balance. For an instance of this, the Anzani motor has three cylinders arranged radially from a central crankcase, the angle between any two of them being 60 degrees, so that the whole angle between the first cylinder and the last is 120 degrees. This engine is of very poor balance, the firing order being 1, 2 3, then a very long interval, then repeat.

WEIGHT OF AEROPLANES

Editor THE AUTOMOBILE:

[2,069]—Will you please inform me as to the average and maximum weight supported, per square foot of plane surface area, by the successful aeroplanes of to-day?

P. S. CROMER.

Bessemer, Ala.

The weight supported per square foot of surface varies widely in different machines. The Wright aeroplane is the lightset, carrying 1.7 pounds per square foot, and the R. E. P. monoplane, a French production which has actually flown, although never for any great distance, attains the maximum figure of 4.1 pounds per square foot. The heaviest machines which have ever had much success are the Blériot monoplanes. M. Blériot's XI, in which he crossed the English Channel, had a ratio between weight and surface of 3.0. His models XII and XIII, designed to carry two and three people respectively, are about the same. The Antoinette monoplane, familiarized by the exploits of Latham, has a ratio of 2.4, and the Voisin biplanes, piloted by Paulhan, Rougier and others, figures out at 2.6 pounds per square foot. The Curtiss biplane belongs in the light-weight class, its ratio being 2.2. It is impossible to make any average figure, as your letter suggests, because no two people could agree on which machines were of sufficient importance to be considered in the averaging process.

The power of the motor is very important in considering the unit weight. As a rule, the greater the weight per square foot, the greater will be the power required of the motor. The Wrights use a motor of but 25-horsepower in a machine weighing empty 880 pounds. Blériot uses the same power motor in a machine of half the weight, after cutting down his plane area.

The beginner who is making a machine should of course make it as light as is consistent with the necessary strength. That leaves a margin to counteract the effect of wrongly shaped planes or insufficient power. The art of properly curving and proportioning the planes is one of the most valuable assets of the old and experienced makers.

NO-FREEZE SOLUTIONS

Editor THE AUTOMOBILE:

[2,070]—What do you use in a radiator to keep the water from freezing in winter?

W. W. RISHELL.

Montgomery, Pa.

This subject has been pretty thoroughly covered in these columns, but as the subject is one of constant interest we will summarize again. The commonest materials in use are mixtures of alcohol (wood or denatured) or glycerine with water; solutions of calcium chloride in water, and light mineral oils. The proportions of the mixtures and the strength of the solutions vary according to the temperature which the cooling medium is desired to withstand without freezing. In the issue of September 30, in answer to letter 2,029, a diagram is given showing the freezing points of various mixtures of alcohol and water; and in the issue of October 7, letter 2,045, may be found a similar table for solutions of calcium chloride. Mixtures of alcohol and glycerine are discussed in answer to letter 2040, same issue. Of the two different alcohols, wood is by far the better to use, since it contains less water and impurities.

HIGH OR LOW, WHICH?

Editor THE AUTOMOBILE:

[2,071]—Will you please advise me through the columns of "The Automobile," which is the best, from an all around point of view, the high or low tension magneto? What are the disadvantages of the two?

JORDAN HARDWARE CO.

Gordon, Neb.

Your question is too broad to receive an exact answer. If we should ask you which was the better, ten-penny or thirty-penny nails, you would not be able to give a definite answer either.

Each type has its advantages and its faithful adherents, who swear by all the gods that it is the best and that the use of any other is arrant foolishness, etc. However, it would appear from the modern tendency, that is, the most modern, that each has its own field. In support of this, it may be stated without fear of contradiction, that the high tension type seems to be increasing in favor for high speed work. On the other hand, the majority of magneto-ignited gas engines, all of which are slow speed units, use the low tension, with make and break.

It is hard to decide just what you mean by "an all-around point of view." Certainly to throw at the dog, neither one would be more advantageous, since the weight and bulk are approximately equal. From the point of view of igniting the charge, it may not be said that either one has superiority.

Disadvantages of each system vary according to who tells about it. If one of the faithful adherents, it has none; if one of the opposition, it has nothing but disadvantages. This is no more than human nature, which is expressed in the same way with reference to another matter, in the familiar saying "What is one man's meat is another man's poison." So, too, with the ignition cranks, one man's make-and-break low tension system is meat to him, but poison to his neighbor, who has a decided preference for the supposedly simpler high tension system.

RUST IN WATER JACKETS

Editor THE AUTOMOBILE:

[2,072]—Kindly advise me how to prevent the water spaces around the cylinders from rusting when the water is drawn off during cold weather.

S. N. BERLIN.

Kewanee, Ill.

The insides of the water jackets of the cylinders are usually given a coat of some rust-proof paint by the maker of the car, before it is delivered, just for such contingencies as you mention. We do not understand from your letter whether you are merely raising a hypothetical question, or whether you have found that the cylinders of your car do actually rust. If the former, you are quite safe. Even if the maker of your car did neglect to coat the inside of the jackets, however, the small amount of rust that will form will not be enough to do any damage. Anything that you might put in the water to prevent rust would do more harm than good.

Studebaker Electrics on a Large Scale

Fig. 1—J. M. Studebaker, Sr., only survivor of the original five Studebaker Brothers, driving a Studebaker Victoria-Phaeton

SOUTH BEND, IND., Oct. 25—Before launching into a description of Studebaker electrics, it may not be out of place to cite history to show that carriage men are quite alive to the advances being made in transportation methods. The best evidence, perhaps, of Studebaker ability to keep in the lead of the times, lies in the very fact that the blacksmith shop started by the five Studebaker brothers, in 1852, was lost to significance when the founders built up a stupendous carriage business which has lasted from that day to this.

It was progress when the Studebakers embarked in the blacksmith effort, and it was progress when they went into the carriage business. This same progress has its monument in South Bend, Ind., taking on the shape of a plant which covers 101 acres of floor space, in which everything required in the line of horse-drawn vehicles may be had, and for whatever purpose is desired.

When the new transportation came into vogue, it found Studebaker Brothers alive to the possibilities, and President J. M. Studebaker, Sr., who is depicted in the title illustration, driving an electric Victoria-phaeton, of the Studebaker make, offers evidence of the convincing character of Studebaker alertness. Mr. Studebaker is the only survivor of the original five Studebaker brothers.

Some years ago, when it was apparent that electric vehicles would have a wide use, the Studebaker company engaged Hayden Eames, then chief engineer of the Electric Vehicle Company, to undertake the task of designing and marketing a class of electric vehicles such as would add to Studebaker prestige. Mr. Eames, following out his invariable plan, undertook the large task in a quiet way, preferring to do the work and let others do the talking.

By a systematic process, and a proper display of skill, the plan has prospered, and it will come as a news item of more than a little purport to most people, that the Studebaker Automobile Company will now go into the building of electric vehicles on a large scale, and in view of the other efforts, in the shape of gasoline automobiles, now well under way, it has been decided to make a separate department of the electric vehicle work. C. H. Tyler, one of the able men of the Studebaker staff, will hold sway over the destiny of this separated project.

Expansion After Several Years of Exacting Work—Let it not be supposed that the present move is as a bolt from a clear sky; on the contrary, the amount of electric vehicle work already done by the Studebakers might be classed as large. The car, as offered in the title illustration, is really a last year's model, but it will be continued in response to a brisk demand, for the company has to its credit a vast output of electrics, spreading over several years of consistent endeavor.

The new idea is to take advantage of experience gained, build cars in accordance with the dictates of this same experience, and place the whole matter on an independent footing, holding a department head of wide experience responsible for the result. Mr. Tyler is in the saddle, the work is being pressed in all directions, and Studebaker electrics are being turned out at a rapid rate.

Fig. 2. is of one of the new models, representing a Victoria-phaeton, and is technically designated as Model 17-D. The illustration depicts the lines and work of the designer sufficiently to demand no further word picturing, excepting that it can not be made to show how carefully the work is done at the plant for making bodies, at South Bend, and a word in this direction may not be too much.

Those who may have had experience with electric vehicles are aware of the differences that must be coped with when bodies are for this class of work rather than for use on gasoline automobiles. No matter how well the battery is constructed, it is prone to spread vapor over the surfaces of the body, and many are the failures which may be directly traced to lack of the necessary precaution in this direction. Knowledge of the corroding influence of gases that may be emitted when batteries are undergoing charge stands in good stead when bodies are being made, and this is a strong point in Studebaker practice. Every particle of material used in the body work is absolutely selected with a view to long life, even though, with proper care, batteries may be so charged as to eliminate substantially all this class of trouble. The idea is not to rely upon the men who charge the batteries, and it is better to assume that the work may not be well executed; in this way chance, and its near residence to failure, is done away with.

Chassis Shows Progress in All Directions—Referring to Fig. 3 of the Model 17 chassis it will be observed that the battery is divided into four sections, and two of these sections are placed forward and back, respectively, on the chassis. In this way the sections are so reduced in weight that they are not difficult for the workmen to handle when they have to be removed from the chassis; and it is equally true that the weight is properly distributed over the chassis, and the riding qualities of the car are therefore superior. This weight distribution has other advantages, as, for illustration, the chassis frame does not have to be heavy, and the spring suspension is relieved of weight.

The sections of the battery are nested in trays made of seasoned oak, which has the property of resisting the action of electrolyte, and the trays are so securely bound, by means of iron bands, that there is an entire absence of cell breakage, while, to protect the iron bands, they are given a substantial coating of an acid-proof compound. The wiring system, connecting the battery with the controller and the motor, is well installed, using a superior grade of especially insulated copper wire for the purpose, taking care to select such sizes of wire as will reduce losses to a minimum, even when the current flowing is that due to very slow speed work with soft going, on a grade, and, of necessity, very high indeed.

Exide Battery Augurs for Mileage and Life—It is true that the size of the battery must be selected in view of the work to be done, but it is a matter of more than a little experience that dictates the right selection. If the battery is intended to give an unusual radius of travel, it must be at the expense of its life, and it is the Studebaker policy to make a happy selection, rather with the expectation of affording an adequate radius of travel of the car, and to trade in favor of every possible increment of life of the battery.

Fig. 2—Model 17-D Victoria-Phaeton with extra seat, divided battery of the Exide type, interlocking control and standard finish

To conserve the battery, ball bearings are used at every point in the transmission system and in the road wheels; but this in itself is not enough. Every car is machined in all its parts with the greatest care, and in the assembling men of skill and a fine sense of discrimination are set to inspect every part. If there is a noticeable addition of friction at any point, the whole undertaking is gone over, and the cause of the friction is eliminated or the parts are cast out.

The motor is so designed that it affords the maximum twisting moment per watt of energy, and, besides reducing the "fixed" losses to the minimum possible, the I^2R losses, so called, are kept within bounds by the judicious use of the right amount of copper wire on the armature and field. The armature is properly laminated, using discs of soft Norway iron, of a special mixture. These, as well as being annealed, are subjected to an aging process, so that the "hysteresis" losses are not only low at the start, but they hold low for the life of the motor. Each disc of iron in the core of the armature is insulated from the other to eliminate "eddy" currents, and, what is more to the point, the insulation is of a permanent character, capable of sustaining all the heat and work to which it may be subjected while under the strain of a load.

The insulation on the wire of the armature is of the finest sea island cotton, wrapped with protecting braid at all necessary points, and each layer is separated from the other by means of insulation of a permanent character. In the same way, the field windings are so protected that they are proof against heat, dampness, and vibration, and retain the high insulation which is necessary if efficiency and long life are to be partners in the enterprise.

The commutator is built up of specially processed segments of copper, so that a uniform hardness is assured for all. The mica used to insulate the segments from each other is of the finest selections from India, of a micrometered thickness, and the whole structure is assembled under great pressure, after which it is chucked and turned to a true diameter. All connections are soldered with a special hard solder, and in the process the joints are scraped to brightness to assure perfect metal-to-metal contact in an electric sense. It is the aim, wherever a joint is made, to have the resistance far less than the normal section of the metal.

Motor Suspension Holds Certain Advantages—The location of the motor is at a point on the chassis just under the seat, and a pair of yoke-like suspenders pass over and around the motor, fastening to a pair of cross members, which in turn fasten to the chassis frame. Shackles, which pass up from the motor frame, on the center line, engage with members which pass down from the pair of yokes, and the motor so suspended is free to respond to adjustment, as the occasion requires, it being the case that the transmission is made, primarily, by means of a Morse "rocker" chain, and finally through a regular sprocket chain.

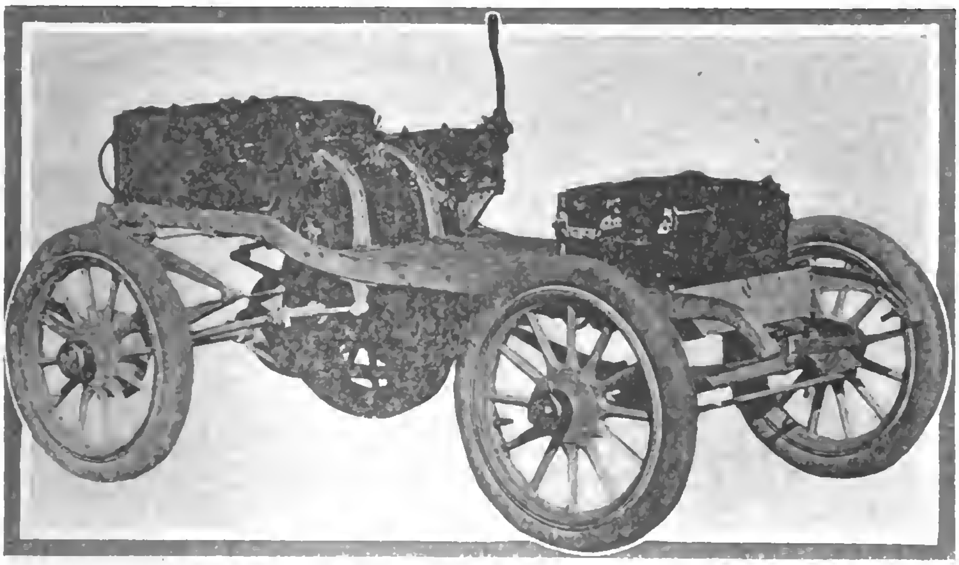

Fig. 3—Model 17 chassis, showing battery in front and rear, motor suspended from yokes, means of adjusting chains, and shaft drive

Fig. 4 shows the chassis from the rear, and the sprocket chain will be seen passing into the housing of the live rear axle, while the Morse chain is enclosed in the "boot" in front of the axle, passing up to the motor. Noise is eliminated, by good mechanical work, but it is insured against by placing oiling devices at every point of vantage, and by the use of suitably contrived chain "boots."

The rear axle is of the floating type, and the driving jaws are of large diameter, with liberal faces and enough of them to assure long life. The material used in the gears, shafts, and other parts of great responsibility, are selected with a view to kinetic work, and by suitable heat-treating, all parts rendered fit.

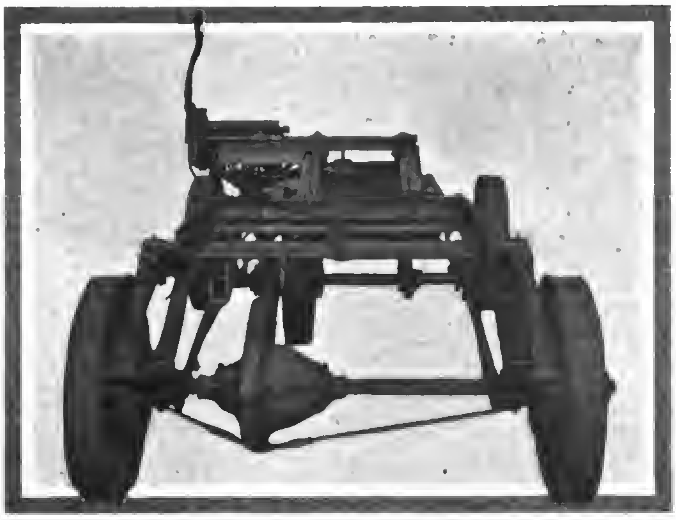

Fig. 4—Rear view of Model 17, showing sprocket chain to live rear axle, boot enclosing Morse "rocker" chain, and full elliptic rear springs

The control system, including its links and levers, is of the straight line design, which is free from "diagonal strains." Considering the use of selected grades of material, ease of manufacture, and ability to determine as to the magnitude of the factor of safety, it conforms to its promise, and the measure of satisfaction is up to the most exacting requirement.

Safeguards for Absent-Minded Users—There are two classes of users who have to be protected against themselves, i.e., the beginner and the operator of much experience who becomes absent-minded. In any event, the design of Studebaker electric vehicles is such that either of these operators will find it impossible to do damage to the cars or hurt themselves. There is only one way that the cars can be started, and that is the right way. By an inter-locking system the five speeds ahead are available progressively, and even if the driver does throw the electrical switch to close the circuit, when the speed lever is out of neutral, nothing will happen. Before the speed lever becomes operative it is necessary to throw it into neutral, release the locking device and close the switch, unless it has been closed at the wrong time.

In starting, suitable resistances are interposed, the idea being to gradually accelerate the car. Watching the ampere meter, which, together with the voltmeter, occupies a place in easy range of vision, discloses how well the control is worked out. There are no sudden and violent fluctuations of current, and the voltage remains practically constant at all times, a feature that will be appreciated by the novice driver as well as by the experienced automobilist.

A dual set of brakes assures ability to stop the car within a short distance, at will, and one of the brakes works by throwing the speed lever back, which is very convenient. The remaining system of brakes works from a foot pedal, which actuates the brake bands in the hubs of the rear wheels within enclosed drums. There are many other nice features of Studebaker cars, the discussion of which will have to be reserved for another time.

SUCCESS FOLLOWS CLOSE ATTENTION TO DETAIL

By C. H. Tyler, Manager Electric Pleasure Vehicle Department Studebaker Automobile Company

IT has long been well appreciated that electrics, as a class, are reliable, primarily due to the continuous twisting moments of the motor (usually designated as "torque"). This torque has a maximum when the motor is starting, and as the motor moves the car the torque, or twisting moment, responds automatically to the demands.

The source of the electric being a battery, it follows that one of great capacity is desirable; but since the life of the battery is involved with the capacity, it also holds that skill, born of experience and judgment, must be the sole guide to success, taking into account the radius of travel of the car which will best serve the ends, and, by limiting the capacity of the battery to the reasonable requirement, produce the maximum of life and the greatest possible return per dollar expended.

If it is true that the motor supplies the requisite twisting moment, taking from the battery the necessary energy, it is also clearly true that a means must be afforded by which the energy may be controlled, and, too, without the exercise of undue care and skill on the part of the operator.

Considering this control requirement as being one of the first essentials, it is necessary to take into account the enormous difficulties involved, in order to appreciate why electric vehicles may have supplied a quota of indifferent success. While on this phase of the subject, it may be as well to point out that the poor success realized in past years was absolutely the product of indifference rather than lack of knowledge, and a display of skill in connection with the motor and battery to the neglect of the controlling system. Perhaps it might be well to add that a fine display of discriminating skill in connection with the leading features as here depicted will fall short of the present high requirement, in the absence of a chassis suitably designed, taking into account the proper suspension of the motor, the right disposition of the battery, and the nesting of the controlling system, as well as proper methods of wiring.

The electric vehicle lends itself so thoroughly to use in the many walks of life, that it would seem almost a crime were the petty faults to remain and the service to be thereby marred. Success in its broadest aspect depends absolutely on the exercise of skill in the design, construction and maintenance of the individual units; but a harmonious corelation of the units must also exist, if the greatest measure of success is to be realized.

From what has been said, it would seem that nothing ever stood in the way of the entire success of electric vehicles, basically considered. But it is also self-evident that this success, in its broadest aspect, is only to be realized in a shop adequately fitted out under the guidance of a corps of engineers, each one of great competence, which, alone, would amount to failure, due to lack of co-operation.

The shop and its facilities, together wtih a corps of engineers, must then, if success be assured, be under the guidance of business men of acumen, and they, in turn, must have at their disposal the potentiality which is only present if ample funds and a wide reputation may be counted upon.

The future of the automobile, which is the matter of the moment, is absolutely assured when all the conditions as enumerated above are thoroughly satisfied.

In the Studebaker establishment, which spreads over 52 years of business in a large way, involving trackless transportation, it has always been the Studebaker idea that a consistent adherence to methods involving conservative but positive advance bring success of the character which accumulates permanence, and in the electrical venture, which started in the Studebaker establishment a few years ago, these same methods were adhered to, and while it looked for a time as if they were not sufficiently aggressive, they have proven to be safe, and Studebaker electrics are now accepted for their sturdy service qualities.

British Automobile Imports and Exports—For September imports of automobiles into Great Britain and Ireland the number of complete cars reported aggregates 243, valued at £81,351; chassis, 358, valued at £101,190. The exports were: 253 complete cars, valued at £103,223; and 17 chassis, valued at £6,269.

Miniature Tonneau Body, the Popular Equipment of the Standard Six—A Clean-Cut Design Throughout

STANDARDIZATION is the keynote of the design, material and workmanship, as well as being a part of the name of the car produced and marketed by the St. Louis Car Company's automobile department, which will be known as the Standard Six.

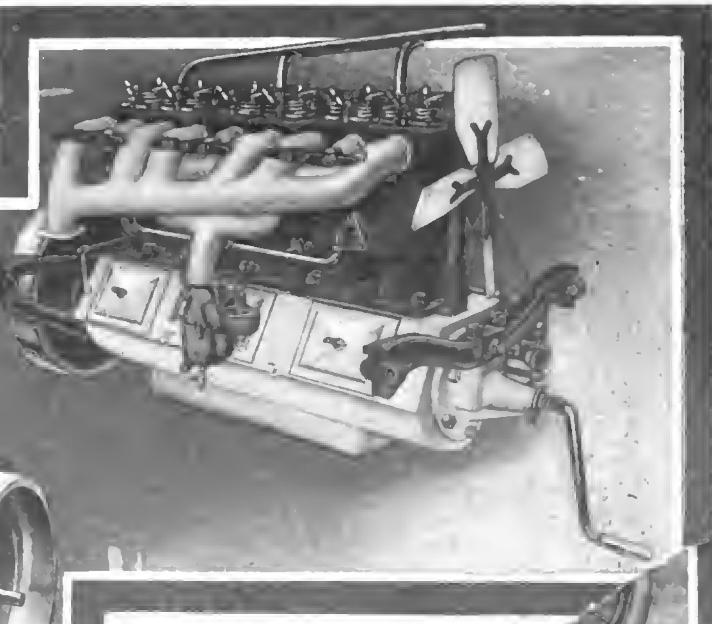
This will be made in but one chassis, which is, however, fitted with four body forms to suit the various needs. The chassis is powered within a six-cylinder engine of comparatively long stroke, although this is not made a feature, the power rating being fixed at 50 horsepower, which is well within the capacity of its size.

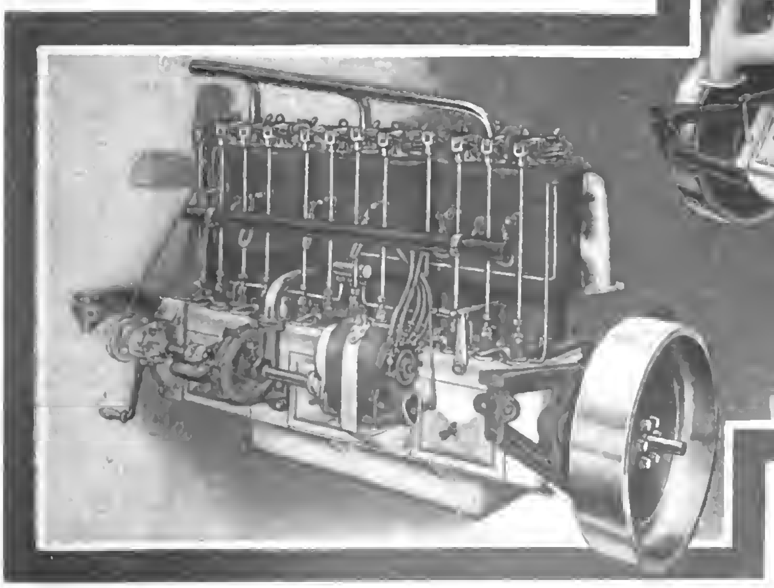
To take up in order the features of the car will be to begin with the most important part and finish with those parts of lesser value. Without a doubt, the motor is the most important part in the whole car and should receive the greatest amount of descriptive detail.

Distinctive Engine Features—First to be noticed are the overhead valves. This placing of the valves is said to be the source of considerable additional power, strictly aside from the more utilitarian one of accessibility. The latter is well worth the consideration of the buyer who is getting his first car, since the old hand will be sure to bear it in mind. The cylinders, of 4½-inch bore and 5-inch stroke, six in number, are cast in pairs. Differing from the usual overhead valve construction is the location of the pipes for both inlet and exhaust on the right side. These pipes are yoke-held, which allows of their ready and very quick removal, either one being removable without disturbing the other. Upon that side of the motor, then, there is nothing but the carbureter and the above-mentioned pipes. The result is again a maximum of accessibility.

Opposite to this are placed the rest of the accessories, that is, the magneto and pump, together with the driving means for both of these and for the fan.

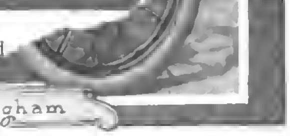
The cylinders are water-jacketed for an unusual length, the whole stroke of the piston being covered. The water passages are unusually large, with easy bends, through which the water is driven by means of the centrifugal pump. The latter is of large diameter, driven at a high speed, which, in combination with an artistically designed radiator of large capacity and sufficient depth, insures reliability of cooling at all times.





Right- and Left-Hand Views of Standard Six Motor

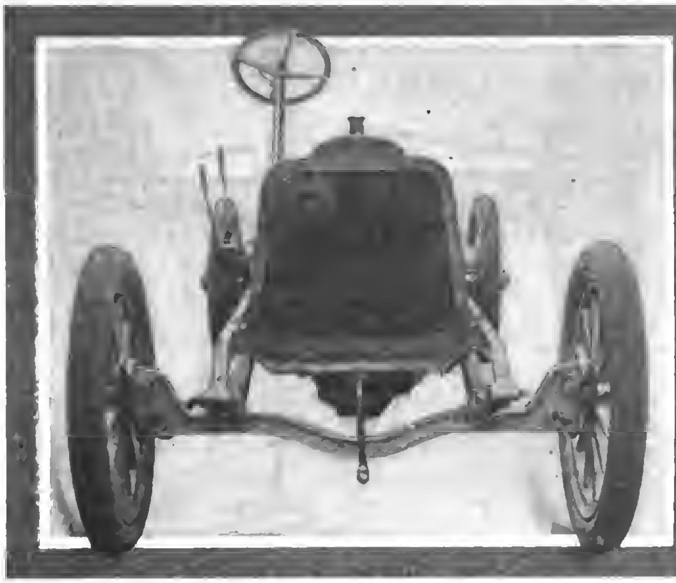
These cylinders are mounted
case of barrel shape. Th
pendence is not plac
arms, these being
case by suitab



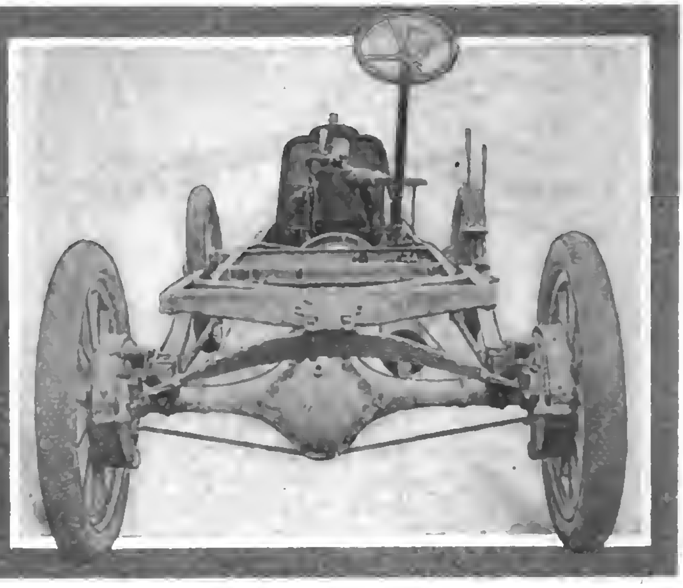
selected material. Being of circular section the ends are closed with circular plates, while the sides have each three large hand holes. With the two end plates and the six side plates removed the inside is as open as it is possible to get it. The lower part of the crankcase forms an oil well from which the lubricating oil is pumped around to the bearings by means of a positively driven pump. This draws its supply from the oil well and maintains a constant level in the bottom of the case. There the lubrication is by splash, the overflow passing through passages on the side of the case to the reservoir below.

Highest Grade Materials Employed Throughout—From one end of the car to the other the materials have been selected for the work they are to do, rather than the reverse. For instance, the crankshaft is of alloy steel. It is a one-piece drop forging, with the flywheel flange at the rear made integral. To prepare it, heat treating is resorted to after it has been finished, finally grinding to an exact size. So, too, with the camshaft. This is a one-piece drop forging, with the cams forged integrally. This form of construction eliminates all pins, keys, cotters, and set screws, with a consequent saving of time, temper and tools.

Inlet and exhaust valves are interchangeable, as are also the



Chassis of Standard Six, as Seen from Front



Rear View of Same, Showing Axle Construction

cages which they work in. Any one valve may be removed immediately by unscrewing a single nut. The valves are mechanically operated though tappet rods, placed on the left side of the motor, on which side the single camshaft is located.

How the Fuel Is Supplied to the Engine—Of course, the engine must be fed. This one eats gasoline and is fed through the medium of a patented, improved carbureter, known as the Carter. It is water-jacketed and has an automatic air control, which may, however, be adjusted from the dashboard. This vaporizer was selected after a prolonged series of tests to determine which one was best suited to the peculiar needs of the six-cylinder motor. It has proven reliable at both extremes of speed, the highest and lowest, as well as rendering good efficient service at any speed in between the two extremes.

Ignition is duplicate in so far as the source of current is concerned. A Remy magneto supplies the current ordinarily, but, if desired, dry cells may be used instead, as well as for quick starting. The single set of plugs are located on the left side of the
play cylinder castings, where they project into the combustion cham-
tures as This location just above the magneto makes the wiring
ment, in the compact and simple. Starting is effected through a
account the prope vided for that purpose and placed on the steer-
of the battery, and the ne truction works to retain the compression
as proper methods of wiring. d is always effective.

The electric vehicle lends itself engine and its accessories
many walks of life, that it would seem that, the transmission. In

the Standard Six the two are combined in a unit. The clutch is of the widely used cone type, the inverted cone being used. The face of the clutch is provided with cork inserts. The transmission affords three forward speeds and one reverse, sliding gears operated on the selective plan being the medium. All gears and shafts are of special steel, heat-treated, hardened and ground to size. The shafts are mounted throughout on annular ball bearings.

Control Is Standard—In so far as any control may be said to be standard, in that it follows the majority of the best cars, this one is standardized. Aside from the gear shifting lever, placed at the driver's right, as is also the emergency brake lever, there are the two usual foot pedals. These operate, respectively, the service brakes and the clutch. Then there are the spark and throttle levers, which are placed on top of the steering wheel, within the rim, so as to be convenient to the fingers.

Chrome-nickel steel is the material of the frame. It is made especially for this six-cylinder car by a reputable maker, and in the making, not only is this best of material used, but it is subjected to unusual care in heat treatment, so that the full benefit may be had of the quality which has made this material preeminent for withstanding shocks. The front end of the frame is narrowed to permit turning short, while the rear end is raised, or, as it is usually spoken of, dropped to lower the center of gravity without reducing the road clearance.

In combination with the upswept rear end, platform springing is resorted to. The front springs remain semi-elliptic in form. All springs are made from special crucible steel, scientifically designed and tempered. The fronts are 40 inches long, the rear side members 42 inches long, and the rear cross member 38 inches. All of them are of the same width, namely, 2 inches. The platform arrangement, it is needless to add, is one in which the frame is supported from three points, with a consequent relief from all twisting strains. All spring joints are lubricated.

Roller Bearings for Both Axles—Both the front and rear axles are mounted upon taper roller bearings. The front is of the I-section drop-forged in a single piece with the spring seats not only forged integral, but widened out as well, which results in a wider bearing for the spring at that point. The cross-connection is placed back of the axle and the knuckles turn on roller bearings, which are arranged to take the thrust coming at that point. The rear axle is of the full-floating type carrying the whole car weight upon a heavy pressed-steel tube, within which the driving axle turns on Timken roller bearings.

Mounted upon the ends of the axles are the wheels, which are of large diameter; 36 inches is the nominal size, while the number of spokes is 12 in each wheel.

Model 74. Waverley Stanhope

INDIANAPOLIS, IND., Oct. 25—A year and a few days have elapsed since October 10, 1908, when the present Waverley Company took over the plant and business of the Pope Motor Car Company in Indianapolis. The preceding year of depression in general business and of financial embarrassment to the then owning company had reduced the operating force of the plant to 150 men, which was soon found inadequate properly to conduct revived business.

The new company was made up of conservative business men, not disposed to spend money foolishly or to plunge into improvements without substantial grounds for the expenditure, and a policy of judicious and steady expansion was at once inaugurated.

To-day the company has on its pay-roll nearly 600 men, and is steadily adding to the force as fast as skilled and competent men can be obtained in its various departments. With upwards of 200,000 square feet of floor space devoted exclusively to the manufacture of electric carriages, delivery wagons, and trucks, it has already been found necessary to operate part of this great establishment night and day to fill orders. If the present rate of increase continues, the management will soon be obliged to put the entire plant on night and day shifts.

When it is remembered that this is a plant which manufactures electric automobiles from the crude raw materials, operating its own forge and machine shops, and making its own tools; building its own bodies from its own patented designs; forging its own axles and making its own wheels; building its own motors, its own patented controller, and its own exclusive chainless driving system; finishing its coach bodies with sixteen different coats of color and varnish in twenty-eight separate and distinct operations, upholstering them with the choicest and most expensive grades of broadcloth and leather, and turning out a completed carriage unexcelled in perfection of mechanical detail and in artistic design and finish, some idea will be gained of the great variety of engineering and manufacturing processes that are carried on in this gigantic establishment. While the new company is celebrating its first anniversary with satisfaction over the successful results of the year's business and with pleasing anticipations of a future of still greater accomplishment, the factory organization looks back upon nearly twenty years of continuous existence and practical achievement.

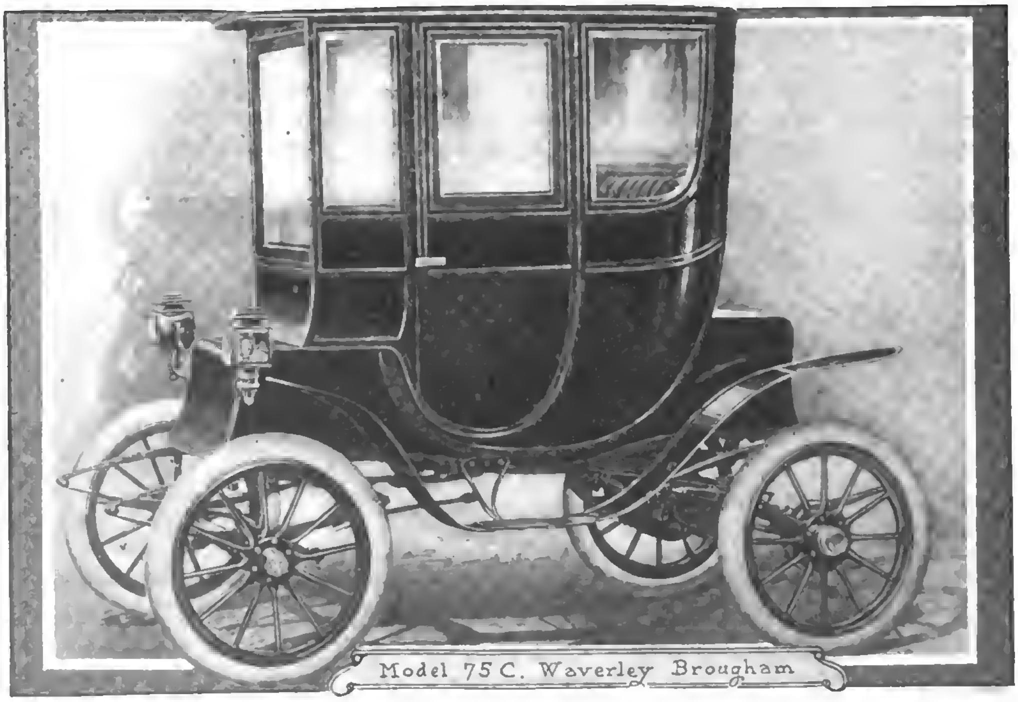
Originally engaged in the business of manufacturing the famous Waverley bicycles, this great factory was among the first to begin experiments with storage battery propulsion as applied to automobiles.

Many costly experiments were made before success was finally achieved, and, as in the beginnings of all new industries, there were not wanting people who were ready to predict that success was impossible. But the leading principles of storage battery propulsion were gradually established by many and frequent trials along different lines.

It soon became evident, for instance, that the electric vehicle and the gasoline touring car were utterly distinct machines, occupying separate fields and coming as little into competition as a family carriage and locomotive. As a matter of fact, the makers of Waverley Electrics saw in the province of the family carriage their especial field and opportunity. They aimed to produce an ideal carriage of high grade, enlarged range, great dependability, superior convenience and delightful freedom from the worries and annoyances that are inseparably connected with all complicated mechanism.

The ultimate success achieved in all these directions was not the result of a sudden inspiration of genius or the product of a single brain. Many minds contributed their share, and the electric carriage of to-day is an evolution of higher types from inferior forms.

With an electric car that has outgrown the experimental stage and has long ago solved all those mechanical problems involved in successful storage battery propulsion, and with a constantly growing demand for this carriage in all quarters of the country,



Model 75 C. Waverley Brougham

the present success of the company and its future prosperity as well are most certainly assured.

The names of the officers and stockholders are as follows: President, William B. Cooley; vice-president and manager, Herbert H. Rice; treasurer, Carl von Hake; secretary and assistant manager, Wilbur C. Johnson. Directors: William B. Cooley, Herbert H. Rice, Joseph C. Schaf, Carl von Hake, Hugh Dougherty, Burton E. Parrott, William F. Kuhn. Other stockholders: Aquilla Q. Kones, Hugh M. Love, Alexander C. Ayres, John R. Love, William Kothe.

Of the 1910 Waverley it may be said that it is an improvement upon all previous models of this company's manufacture. The new Waverley driving system makes the use of either solid or pneumatic tires perfectly practicable and satisfactory; the enlarged wheelbase, increased size of the wheel, and the use of full elliptical springs on all new models has added to the comfort of the rider and the serviceability of the machines under all conditions of roads; while the peculiar compactness of build and the beauty of the Waverley designs has not suffered in any particular from the changes made. The fact that Waverleys of this year's design are making distances of from eighty to ninety miles on a single charge without extra batteries and without being stripped for special test runs, has added greatly to the interest in and demand for this make of electrics.

Such results have been reported from many different parts of the country. Thus, M. C. Mathias, superintendent of fire alarms at Reading, Pa., who runs a Waverley runabout, writes: "I have run as far as 90 miles with this machine on one charge, and *never* have to go to the garage for a recharge until I have 70 miles out of it."

This experience is not confined to any one section of the country, or any one person, as is well shown by a parallel case in the East. Thus, the Dodge Motor Vehicle Company of Boston wrote to the factory under date of August 12, saying: "We sold this car (Model 75-C) to Mrs. Hyde, of Allston, Mass., after we had taken one running discharge. The writer then took Mrs. Hyde and her daughter for a ride of 81 miles, from Boston to Marblehead Neck and return to Allston. The car after running this distance, up hill and down, was practically as strong as at starting. We think that you need not hesitate to say that this model with a 32 cell battery will run 100 miles with three or four people."

Many instances of mileage are available and of significance chiefly to show that the days of the electric that will give but fifteen to twenty miles on a charge have gone by. It is now possible to equip any electric machine to give almost any required mileage. Waverleys, for instance, have given 142 miles on a charge when such distances were demanded; but a fifty-mile ride in an electric or any other form of private carriage is as much as most people care for, and it is well understood that there is economy in the standard instead of hy-cap batteries.

HOW WILLYS ENTERED AUTO INDUSTRY

Probably the American boy does not live who has not at one time or another been told that he may be president if he so wills it, states the Toledo *Times*. But how few actually realize that wish! On the other hand, perhaps as much honor attaches to the great captains of industry, which positions, like the other, go to the men with the ability. As a field for the latter, probably no one business offers more opportunity for the young man to rise than the automobile industry, yet most of the large automobile firms have been built up from a small beginning.

One that most assuredly has is that of the Toledo Motor Company, of Indianapolis, Ind., and Toledo, O., which is presided over by John N. Willys. The story of the rise of Willys from practically nothing to president of the largest single company within two years reads like a fairy tale.

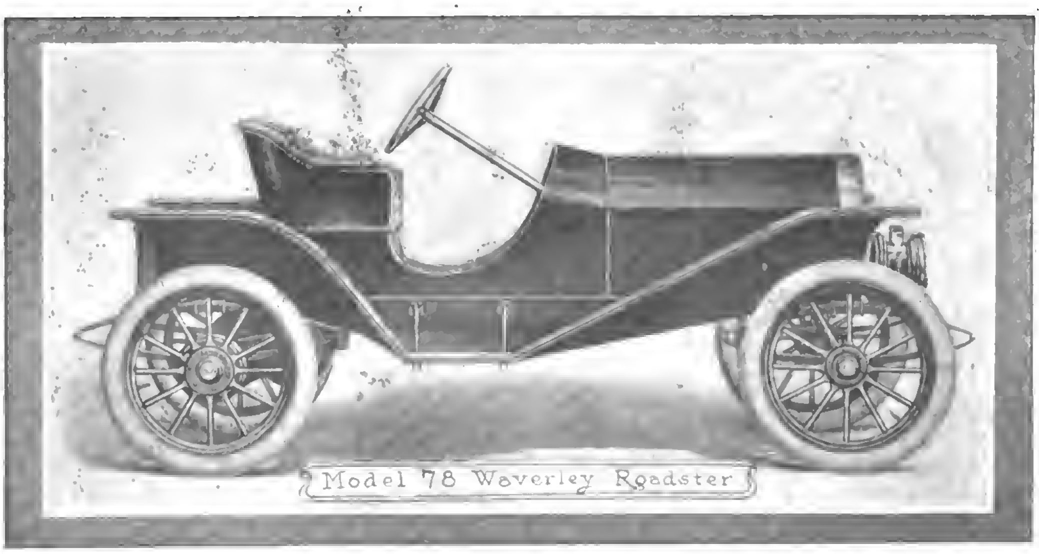
Like many another young man, mechanically inclined, Mr. Willys entered the bicycle business in Canandaigua, N. Y., where his family then lived. From the bicycle to the automobile business was as logical a step for him as it was for a number of the manufacturers whose product he handled. Removing to Elmira, N. Y., he had established the Elmira Sales Company, the object of which was to sell bicycles. Following that came the organization of the American Motor Car Sales Company with headquarters at Indianapolis, Ind.

The latter firm was organized by him for the sole purpose of promoting the sales of the Overland, American and Marion, all Indianapolis-built cars. After several months of thriving business Willys one day found himself in the anomalous position of having sold something that he could not deliver. That is, he had signed contracts for and received a deposit on some 500 Overland cars which were not forthcoming on the date set.

A flying visit to the factory showed the latter to be practically closed, and some questioning resulted in the information that the plant was to go into the hands of a receiver on the following day for want of $450 with which to pay back salaries of workmen.

With characteristic energy, Willys raised $500 practically on his good name, and on a Sunday at that, using this money the following day to straighten out the wages question. More than that, he devised a plan to satisfy the creditors temporarily, thus allowing the company to make enough cars to permit him to fulfill his contracts. Through the medium of this deal he obtained control of the Overland plant.

At that time, September, 1908, no one appreciated better than Willys himself that the company's manufacturing facilities were not adequate, the factory having but 30,000 feet of floor space. So he took over the Marion plant, in which circumstances favored him to the extent that it was far from being on a hopeful basis. Under his direction the two plants were able to exceed the estimated output of 1,500 cars, actually turning out some 4,075 during 1908. Once again confronted with a lack of factory facilities, he obtained an option on thirty acres of land near Indianapolis and planned a monster factory. Before, however, this deal had been closed, he heard of the Pope-Toledo plant, which was then on the market. Within 48 hours after hearing of it he closed a deal in New York City with Col. Albert Pope for the purchase of the plant. This property is now being renovated and put into shape to turn out 12,000 cars for 1910, while the output planned for Indianapolis is 8,000 cars, a total for Willys plants of 20,000.



Model 78 Waverley Roadster

Levi Fletcher, and His "Steam Road Engine" in 1894

PORTLAND, ME., Oct. 25—Stored away in the old Fletcher barn at Hollis is the first automobile ever built in the State of Maine, and possibly the first one ever run over the roads of the Pine Tree State. This is the famous "steam road engine," built by Levi Fletcher some ten or fifteen years ago. Levi Fletcher, who constructed the vehicle, is dead, and thereby passed away a genius, who died of a broken heart.

Mr. Fletcher conceived the idea of a carriage running along the roads without horses. He said that locomotives could make their way along tracks and steam rollers could go through the streets. Why not, then, a pleasure or commercial vehicle driven by the same mysterious force? He told his plans to no one, but quietly went to work on what he conceived would be a steam road engine. He had never seen an automobile nor heard of one, as there were only a very few in existence at that time, and they were in the experimental stage.

He gathered a bit of iron here, some brass there and piping in another place. When he had secured the requisite amount of material he assembled the parts, and the "steam road carriage" was the result. It was not a sightly looking contrivance, but the principle was right, and it ran.

Out upon the road the machine was pushed from the barn and the neighbors stood around in astonishment. With much snorting, and grinding and hissing, the steam vehicle went slowly ahead. It made excellent progress down a grade, but when it struck a hill there was absolutely "nothing doing." Levi saw there must be improvements, so the contrivance was hauled back to the barn.

Repairs and alterations were made and the carriage was so fixed up that he could spin along a country road at a fair rate of speed, but it always balked at hills. One day Levi was puttering about the machine in the barn when he was attracted by a shout, and what was his astonishment to see a real automobile go by. He gazed in open-mouthed wonder, dropped his tools and went into the house. He never again touched his steam carriage and seemed to lose all interest in life. It is said he died of a broken heart.

OHIO LAW DECLARED CONSTITUTIONAL

COLUMBUS, O., Oct. 25—By a decision of the Ohio Supreme Court handed down recently, the Ohio automobile law has been declared to be in accordance with the constitution. The decision is the outcome of an effort on the part of T. M. Drolesbaugh, of Crawford county, to avoid registering his car. When he was arrested he pleaded the unconstitutionality of the State law, on the ground that it was an arbitrary discrimination against automobiles in favor of horse-drawn vehicles, and that it violated Article I, section 2 of the Ohio constitution. The lower courts sustained the constitutionality and the decision was reaffirmed by the highest State tribunal.

HOW THE PNEUMATIC, FINALLY, WAS TESTED

The *Allgemeine Automobile Zeitung*, Berlin, recently published some chapters of incidents of days that are past, some of the anecdotes being of so delightful a character that they will certainly interest American readers as well as those of the Fatherland. In unfolding the tale of the early trials of the Michelin pneumatic, the writer says:

It was a Benz car of the very earliest kind that was destined to take part in the Paris-Bordeaux-Paris race of 1895, equipped with Michelin tires. It was proposed to go over the course with it about three months before the race, and André Michelin was to meet the vehicle at Poitiers. Of course, the whole factory turned out to watch the *Swallow's* arrival at Clermont, and in the very earliest hours of the morning a group of young men posted themselves on the stiffest part of the hill—and waited. When it turned 4 a. m., and nothing was to be seen, they grew impatient, and questioned an old farmer coming along with a herd of cows as to whether he had seen a "carriage without a horse." The old man, naturally thinking they were enjoying a joke at his expense, waxed wroth and shouted: "A carriage without a horse! You cheeky lads, how dare you try to fool an old man like me?"

But at the very minute of speaking a huge cloud of smoke in the distance heralded the approach of the Benz, clambering painfully up the hill, to the great astonishment of the old man, who was thrown into a state of veritable panic by the approaching monster. Unfortunately, the car had an inglorious end without participating in the race, as, shortly before the date, it was found that the cylinder had burst and the water had entered the compression chamber.

It had taken the Clermont people three whole months to find out why the machine of this flighty *Swallow* so often went on strike. Out of the parts of the *Swallow* a new car was built with the greatest speed and hurry, with the help of a 6-horsepower Daimler marine motor bought in Cannstatt. This vehicle was dubbed the *Spiderweb* on account of its light weight, which, it must be acknowledged, existed more in the minds of the constructors than in reality. Only, on building the chassis, which was concluded before the motor came to hand, it was forgotten to leave the necessary space for the engine, and afterwards it had to be put in as best it could. The car, which had no differential, could, however, attain a speed of 35 to 40 kilometers, with its back axle coupled direct with the engine.

Fate cruelly overtook this marvelous vehicle on its first trial, for shortly after its departure the following laconic telegram arrived: "Ran into tree on third speed near Moulins." This tree, unfortunately, did not bend, but sternly rejected the car, with the result that driver and mechanician were thrown into a field.

Undaunted, a third car, a 2 1-2-horsepower Peugeot, was purchased, and a 4-horsepower Daimler engine put into it, which also found its resting-place on the back axle. It was fearfully difficult to steer this vehicle; the car persisted in permanently zigzagging, and this remarkable quality made a great deal of skill imperative to get out of the way of approaching vehicles. Nevertheless, it was determined to take part in the race with it! It was equipped with a lot of spares, in a tool-box of such vast dimensions that it looked like a perambulating arsenal. Thus armed, the car, which weighed 1,400 kilogrammes, set out on its trial runs, during which time it twice ran amuck owing to its miserable steering. The first time all went well, but the second time the mishap occurred at night during a lamp test, in consequence of the forgetfulness of a workman who had carried out an alteration in the wheels, but had forgotten to readjust the brakes. As the back axle had no differential, a strong pull of the hand-brake sufficed to completely throw the car round, and, colliding with a telegraph pole, it threw the whole lot into the field. Of course, the car promptly caught fire, as it was fitted with slow-tube ignition, and burnt down to the metal parts. But it was repaired in time and started in the race, thereby enabling the tires to be tested at least, after this chapter of accidents.

SOME CONCISE INFORMATION FOR EUROPEAN TOURING

WITH just enough detail to serve as a guide and enough illustrations to give the reader a good idea of what may be seen in a 4,000-mile tour of Europe, a book recently issued by the Pierce-Arrow Motor Car Company, of Buffalo, presents a rather unique total of information. In one way the book will prove a boon to those Americans who contemplate taking their cars across the Atlantic for touring. It presents the itinerary of an American with his American car and driver who went to Europe without any definite plans, just as many another citizen of the United States has done.

The American's time was limited and his ideas of where he wanted to go and what he wanted to see were vague and general. The car had been shipped direct from the factory at Buffalo, consigned to the company's hranch in Paris and so, naturally,

A Medieval Street in Picturesque Loches

The Garden of the Fountains at Nimes

that was the first objective point of the tourist. The manager of the Paris branch of the Pierce-Arrow Company had been informed of the coming and had also been given the greatest latitude in making arrangements.

The advantage of this plan was apparent when the tourist came to make his arrangements. His crated car had been met at the dock by a representative of the branch and driven overland to Paris, there to await him. A courier-valet who spoke English, French, Spanish, Italian, Austrian and German, maps and a store of information concerning road conditions were ready for his inspection, and membership in the Touring Club of France had been arranged. A deposit was made with the Touring Club to cover duties in the countries to be visited, as follows: France, 1,290 francs; Italy, 600 francs; Austria, 2,258 francs; Germany, 539 francs: total $4,687 francs. When this deposit was made a triptyque was given to the tourist and this enabled him to cross the various frontiers without the usual customs formalities other than the signing of the triptyque. When the return to Paris was made and the triptyque, properly signed, given over to the Touring Club of France, the deposit was returned, only a small fee being charged for the accommodations and courtesies the club had furnished.

From the maps provided by the Pierce-Arrow agency and the information furnished by the Touring Club a route was selected

Peasant Women of the Pyrenees Mountains

that led through a beautiful chateau district of France to the east cost of that country and then to the border of Spain long enough for a one-day trip across its boundaries. The route chosen then led along the southern coast of France into Italy and north to Lake Como, then down through that part of Italy which is more familiar to the historian. From there the trip north was made by easy stages through southeastern Austria and the eastern part of Germany, until the tourist again entered France and turned the car over to the Paris branch of the company for shipment home. In the book the complete route is marked by night stops and a more detailed idea of the country traversed is shown by the list of these.

The first four nights were spent at Tours while the chateau country was being seen, and from then on the night stops were Bordeaux, Biarritz, Pau, Toulouse, Nimes, Cannes, Monte Carlo, Genoa, Como, Bellagio, Verona, Venice, Bologna, Florence Perugia, Rome, Naples, Siena, Pisa, Pierre di Cadore, Inusbruck, Bregenz, Freiburg, Metz and Paris. Luncheon stops are also mentioned in the book and only once was it necessary to carry luncheon in the car owing to the absence of a good inn or café on the day's run, this being between Naples and Rome, when the old Appian way is used for a part of the distance.

A new use for picture postcards is told of in the book. As soon as the tourist reached the city of any considerable size he could buy a number of these

Arcaded Street and Principal Square, Genoa

Bologna's Leaning Towers

Arcaded Street to Cathedral

cards, showing the principal places of interest in the city and from them would be enabled to select the places he wished to visit. A courier would then be engaged, at the leading hotel generally, and with his assistance the places selected could be seen to their best advantage.

In the back of the book is a map, 16 x 19 inches in size, showing the principal roads through the countries visited, the cities and towns, boundary lines, distances and road conditions. The route used by the tourist who furnished the material for the book is shown and his night stopping places are indicated by black circles. In addition to the map the book is well illustrated by views of buildings, cities and mountain scenes encountered on the trip.

It is not the intention of the company in issuing this book to prescribe a route that should be followed by motor car tourists in Europe, but merely to show what can be done by an American owner of an American car who, with his time limited, goes to Europe to see as much of the instructive, beautiful and entertaining as he can. Whether he wishes, in a general way, to follow the route shown or not, the book contains a store of information in the most concise form.

Altogether, the mileage of the car was 5,170. Of this, 1,268 miles were taken up by the trip from Havre to Paris and the return and the side trips made during the tour. No accurate record of the mileage of the side trips was kept, and for this reason the only distances recorded are those between the night stops. These are:

	Kilometers	Miles
Paris to Tours	232	144
Tours to side trip	147	92
Tours to side trip	160	99
Tours to side trip	193	120
Tours to Bordeaux	313	194
Bordeaux to Biarritz	264	164
Biarritz to side trip	108	67
Biarritz to Pau	104	65
Pau to Toulouse	229	142
Toulouse to Nimes	310	193
Nimes to Cannes	299	186
Cannes to Monte Carlo	54	34

Heidelberg to Metz	215	134
Metz to Paris	290	180
Total	6,279	3,902

HOW THE AUTOMOBILE WASHED THE CLOTHES

By R. J. GRISWOLD

EXTREMES touch when an automobile figures in the Monday washing, but that is what certain residents of a Michigan town saw not so long ago. Seeing is believing, and although I had to turn out at 5 o'clock in the morning to witness the demonstration, it was worth the effort.

This is how it happened. A friend of mine who lives in the country had a guest from the city staying with him for a couple of weeks. A neighbor who was a temporary member of the Merry Widowers' Club, owing to the absence of his wife and family, was also sharing his hospitality. When the end of the week rolled around there was naturally an extra large washing. This did not cause the housewife any worry until, late Saturday afternoon she received a note from the lady of the tubs stating that the latter was going on a short vacation and would be unable to be present as usual Monday morning. Madam must needs make other arrangements. The C. Q. D. signal was displayed; they scoured the neighborhood, but not a washwoman was to be found. Finally in utter distress the lady of the house went to her husband and said: "George, what *shall* we do?"

George simply smiled. "Don't worry, my dear," said he. "Keep cool and take it easy. A plan has occurred to me which I think will take care of the situation. Just have the washing ready Monday morning, bright and early, and leave the rest to me."

The evening and the following day were spent in a round of pleasure, with George always the leader, undisturbed by the burden of responsibility which he had assumed.

Sunday afternoon George slipped out to the garage, and patting his car on the hood, said: "Old fellow, it's you for the washing to-morrow."

Donning his overalls, he jacked up the rear axle and placed a broomstick through the right rear wheel to hold it stationary. After taking off the tire of the other rear wheel he brought in the washing machine, fastening it with cleats to keep it from moving. With two trunk straps buckled together he made an endless belt which he placed over the left rear wheel and the wheel of the washing machine.

The rest was easy. I was tipped off to appear on the scene at five in the morning. When I entered the garage, rubbing my eyes, George was comfortably seated in the front seat, smoking a cigar. The car was chugging along on middle gear, and the washing machine was running as it had never run before. The hired girl and the man of all work were kept on the jump putting in and taking out the clothes. I couldn't help thinking of the feelings of that poor old washing machine. It certainly must have thought that it had struck some one with an arm of iron.

AUTOS COMPETE WITH ELECTRIC LINES

Increased fares on the electric interurban lines running out of Tacoma, Wash., caused the establishment of an automobile service between that city, Brookville, Fife and Milton. The increase made the fare to Milton 26 cents, instead of the old rate of 15 cents, which the automobile line will endeavor to maintain.

EXPENSES OF AN AMERICAN'S TRIP IN EUROPE

An IDEAL trip of 6,700 miles through England, France and Algeria, which was made last Summer by A. Lowes Dickinson, of the Automobile Club of America, in a 40-horsepower Locomobile, offers to prospective imitators a complete table of the expenses which may be looked for. Mr. Dickinson kept a log-book of the tour, showing in detail all expenditures, and averaged these for mileage. Automobilists who contemplate taking their cars abroad and adopting the most delightful way of seeing a foreign country, may obtain many useful pointers from his figures.

Five weeks were spent on British soil. From the landing at Southampton the route lay across the English downs, through masses of heather, to Castle Malwood, the seat of Lady Harcourt, and the Rufus Stone, where William Rufus was killed in the year 1100. Thence through the Great Forest to the Avon Valley, stopping for luncheon at the quaint White Hart Inn, at Salisbury, the party went on through Amesbury and past the big military camp at Bulford, concluding the first day's run at Winchester. The remainder of the first week was spent in leisurely touring to London via Brighton, visiting on the way St. Leonnards, Hythe, Charing, with its picturesque old half-timbered house, Yew Tree Farm, beautiful Leeds Castle and steep Ryegate Hill, the route made famous by coaching parties.

While at the English metropolis a number of days were spent in making various short and long trips about the city, among them being jaunts to Windsor Castle, Baldock, Richmond Park, Gad's Hill, the home of Charles Dickens, and other places of note.

After completing 2,000 miles in England the car was shipped to Boulogne, France. At the latter place it was necessary to wait four hours for driving licenses, the usual test drive being required. Striking out over the Route Nationale and into the valley of the Somme, the first night stop was made at Amiens, 76 miles from Boulogne. After spending a morning in exploring the Cathedral the party threaded its way over the undulating roads and chalk table land through Breteuil, Beauvais, Allone and Meru, where the beauty of the country became greater. At Conflans, the Seine was crossed for the first time, the route then lying through the Forêt de St. Germain country. At first the roads were bad, but upon reaching Suresnes and passing into the Bois de Boulogne (where duty has to be paid on gasoline) and on to Paris, the road is all that is to be desired.

From the French capital jaunts were made through the Chateau country, St. Cyr, Rambouillet, Voisins and Chartres. After an exploration of the ancient Chateau de Blois and nearby spots the party bore over to Tours, then down the Loire Valley to Liginières, lunching at inns, and thence driving into the Indre Valley and southward to historic Poitiers.

Leaving bright and early, a strenuous run of 200 miles was made toward the Pyrenees, ending in Agen at 8:30 in the evening. Several days were then spent journeying a few hundred miles through Coarraze, Lourdes, Pau, the Tournay country, before the Mediterranean was sighted. A visit was made to the Maison Carrée, the almost perfect specimen of an old Roman temple, with the old Roman baths nearby, and thence down to Avignon.

The road from here through Aix, Cannes and Nice was uninteresting, being much cut up with wine traffic. Pushing onward the following day on the wonderful Corniche d'Or road, along the beautiful country of the Gulf of St. Tropez, and through the winding mountains with their gorgeous scenery, the ride into Marseilles (1,725 miles from Boulogne) was a delight.

After some annoying trouble occupying several hours the car was loaded onto a steamer and run through a terribly rough sea to Algiers in about 30 hours. The freight rate is 227 francs for a car weighing 3,910 pounds, and the transportation company charges 100 francs additional for insurance, but as there is great doubt as to what this insurance actually covers, it is better to insure through Lloyds, which can be done for one-quarter of one per cent. There are several lines by which a car can be carried to Algiers.

The party spent five weeks in Algeria, visiting both known and remote parts, upon which notes in the log-book of the Loco are quite lengthy and would fill a small-sized book. The return trip was made via Marseilles and then direct to Havre in six days.

The following statement of running cost, kept very accurately, gives a fair idea of what an automobilist has to spend to take his family abroad on a 6,700 mile trip, with a car of ample power:

Cost per mile run.	In England 30 running days, 2,000 miles	In France & Algeria 47 running days, 4,700 miles
Gasoline	$0.031	$0.0496
Oil	.0092	.0063
Repairs and spare parts	.0069	.0065
Supplies and sundries	.0045	.0039
Garage, cleaning, etc	.0176	.0142
Tire expenses	.0786	.0729
Licenses	.0076	.0049
Chauffeur's board and expenses	.0446	.0294
	.20	.1877
Freight, England to France and France to Algiers and back		.0381
Total cost per mile	.20	.2258

Number of gallons used, 215
Miles per gallon on gasoline used, 9.3

Hotel expenses, leaving out of account Paris and Nice, where any price may be paid, averaged throughout France and Algeria $4 per day each. This included wine, tips and all expenses, and in every case rooms containing two beds, which are more expensive. The chauffeur's expenses averaged $1.75 a day.

Mr. Dickinson's 40-H.P. Locomobile at Gavarnie, France

UNIFORM REGULATIONS ABROAD

Common sense triumphed again over medieval provincialism when France, Germany, Belgium, Italy, Bulgaria, Roumania, Montenegro, Servia and Monaco signed the international automobile regulations. These nations may henceforth be regarded as the promised lands of the automobilist. Although few Americans may expect to visit the countries which form the latter half of the list—indeed we suspect that few could locate them on the map, except the very last one—it will readily be admitted that they have proved themselves worthy to be enrolled among the progressive nations of the world, and deserve a share of the benefits of intercourse by automobile.

The regulations thus adopted are few and simple, but important. They embody the very points which every automobilist hopes to find soon in the laws of our several States. The examination of drivers and cars and the issuance of an international license, the regulation of lights and signals, and the adoption of uniform road signs; finally, the elimination of customs annoyances—all these are calculated to make touring in the favored countries an unalloyed pleasure.

Great Britain alone, of the commonly traveled European countries, proved recalcitrant. England resemble the United States in many ways. Both apparently regard the extortion of a few dollars revenue as of more importance than the safety of the general public; thus they issue driving licenses to anyone who can pay the necessary fee and are unwilling to go to the bother and expense of an examination. In both countries, too, the political powers in supremacy appear to be afraid to entrust their representatives with any degree of responsibility. We may talk of the dilatoriness and inefficiency of the Latin races, but in this instance they acted with remarkable promptness and certainty. Great Britain, however, still has a chance to redeem herself.

Nor is the United States entirely without hope of being able to join the ranks of progress. The American Automobile Association has in preparation a bill to be presented to the next Congress, which embodies most of the features of the international regulations, as well as others more adapted to the particular needs of the country. That phase of the bill which is of the greatest importance, however, does not lie in its individual features, but in the assumption by the Federal Government of the right to control automobile traffic as being interstate.

FACTORS INFLUENCING PRODUCTION

Hardly a week passes without the addition of several new concerns to the already long list of automobile manufacturers, or, more correctly, makers. This is a matter causing some apprehension, for those inclined to worry figure that the output of the newcomers will be large, and this, added to the already swollen estimates of 1910 productions, brings the grand total for the year up to figures which are alarming to contemplate. Certainly, if every firm produces the full number of cars now credited to it, there will be overproduction of the worst kind.

But few of the hurriedly launched companies weather the first season; a smaller number produce cars at all, and a scant percentage approach quantity estimates.

This is a statement which is borne out by facts and figures relative to companies in the past and may readily be verified. The starting of a new concern of this sort, to manufacture or even assemble automobiles, requires a number of points to produce ultimate success, and the lack of any one of them spells failure.

Thus there must be sufficient capital, there must be the ability to use it wisely, there must be an able design, and there must, above all, be mechanical ability and shop equipment to produce the design in actuality. From the lack of any one of these the new concern will go under. Lack of capital hampers many firms, and, according to statistics, produces about one-fourth of all failures. In the present day and time, with a parts famine imminent, this would have great bearing. The ability to use the capital wisely and well probably goes with the first, or amount of capital, since in the end it amounts to the same thing. The man or men unable to use their capital to the best advantage would practically never have enough.

The design is of paramount importance, too, for if the designer fall down on a very small point, perhaps so small as to be thought insignificant, and the first cars do not take well, the result is the same as if the design had been worthless. More than this, without a shop equipped properly to work out the designer's ideas his plans may become worthless.

So it may be said that there are many components which enter into the makeup of a successful automobile, of which few of the mushroom companies now springing up over night possess all, and many of whom possess not even a majority of them.

E.-M.-F. TO HAVE CANADIAN PLANT

Detroit, Oct. 25—Not content with controlling a big slice of the automobile business on this side of the border the E.-M.-F. Company is going after foreign trade in earnest.

The first step in the consummation of this plan is the establishment of a $400,000 automobile plant at Walkerville, Canada, just across the river from Detroit, and the organization of the "E.-M.-F. Company of Canada." The concern will be merely a subsidiary company of the Detroit firm, although new capital has been interested in the undertaking. Foremost among the incorporators are Frederick H. and J. Harrington Walker, of the Hiram Walker & Sons Company, leading distillers in the dominion, and it is understood that they, together with Dr. J. B. Book, Charles L. Palms and Walter E. Flanders, of the Detroit E.-M.-F. Company, will furnish all the money needed. Mr. Flanders is president and general manager of the new concern, and Robert M. Brownson, secretary and treasurer. A factory building has been secured in Walkerville and machinery will be installed sufficient to ultimately give a daily capacity of 100 E.-M.-F. "30" and Studebaker-Flanders "20" cars.

The E.-M.-F. Company of Canada will not, it is announced, content itself with the trade of the dominion. It has enjoyed an excellent demand for cars from Canadian points, but there was always a heavy duty to contend with. This difficulty will now be obviated. Furthermore, an inviting field is found in the other portions of the British Empire, particularly India, New Zealand and Australia. By shipping its cars from a Canadian instead of an American port the company will be entitled to a 99 per cent. rebate in duties, an item well worth considering and which will give it a decided advantage over manufacturers on this side of the border. The present plan has been under consideration for some time.

DETROIT DEALERS' SHOW TO BE BIG

Detroit, Oct. 25—January 24-29, inclusive, are the dates selected by the Detroit Auto Dealers' Association for its third annual automobile show, which will be held in the Wayne Hotel Gardens. This is not Detroit's third automobile show, but the third one under the auspices of the dealers' association. To deal in figures, it is the eighth annual exhibit that has been held in the City of the Straits, and each year has seen something better than its predecessor.

For the 1910 show there is 35,000 square feet of space available, and, inasmuch as it falls at the interval between the New York and Chicago exhibitions, there is every reason to believe that the exhibits will be more varied than ever. The dealers' association has voted $10,000 to be utilized in decorations for the gardens, which is $2,000 more than was voted for last year's show, and exhibitors will not be required to decorate, that expense being included in the price of space.

John Gillispie, who so successfully handled the arrangements for the ceremonies in connection with the start of the Glidden Tour from Detroit last summer, has been chosen manager.

DETROIT ADDS THE ANHUT CAR

Detroit, Oct. 25—If this city fails to produce its full proportion of the automobiles manufactured the coming season it will be no fault of sundry ambitious and optimistic Detroiters. The organization of a new automobile company is of weekly occurrence.

The latest to be added to a long string is the Anhut Motor Car Company, capitalized at $150,000, which has been organized by State Senator John N. Anhut. Others in the company are H. H. Lonsby, Thomas F. Ahern and John B. Chaddock, Detroit, and Charles Lonsby, of Mt. Clemens.

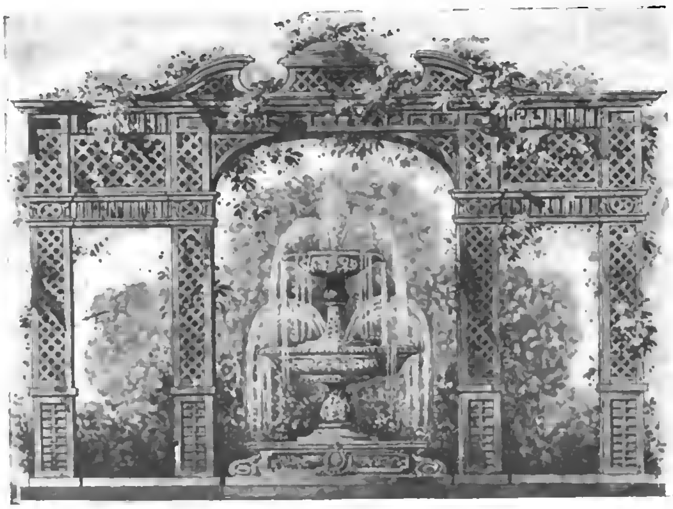
The company expects to begin manufacturing cars about the first of the year, and hopes to build 1,000 36-horsepower machines the first year.

This makes no less than seven automobile manufacturing companies that have been organized here in the last two months.

PALACE ELECTRICAL AND WATER EFFECTS

When the tenth annual show of the A. M. C. M. A. opens in Grand Central Palace, New Year's eve, the public and exhibitors will be treated to a combination of electrical and water effects such as has never been seen before. The decorators of the Palace, Unitt & Wickcs, the Hudson-Fulton decorators for the city of New York, have evolved a decorative scheme this time, which including as it does some wonderful scenic features involving the liberal use of electricity and water, is said to surpass anything ever produced in this line.

Stationed at the end of the main hall, where last year was placed the figures of "Age Instructing Youth," will be a marble fountain. The base of this, in which real water will be used in great quantities, supplied by a rotary pump, will measure 16 feet across by 14 feet high. Back of the fountain, so placed as to enhance the water and electrical effect, will be a hugh mirror of plate glass. Surrounding the two will be a peristyle, 40 by 25 feet in extent, and coverd with green trellis work. At the base of the fountain and around the peristyle, trees, shrubbery and potted plants will be placed. The effect will be spectacular in every sense of the word, and at the same time a suitable blending of harmonious colors will lend an Arabian Nights glamour to the decorative scheme as a whole.



Electrical Fountain for Grand Central Palace Show

PLANS FOR BOSTON'S BIG SHOW

Boston, Oct. 25—Application blanks for space in the eighth annual Boston Automobile Show, to be held March 5 to 12, 1910, in Mechanics Building under the auspices of the Boston Automobile Dealers' Association, have been sent out by General Manager Chester I. Campbell. For the show there will be available 105,000 square feet of show space, but the applications that already have been filed cover approximately eighty per cent. of the space. The preliminary allotment to members of the Dealers' Association has been made, and also the allotment to the members of the Motor and Accessories Manufacturers.

The show will be upon similar lines to those in the past, but the great increase in the number of pleasure cars has made it necessary for Manager Campbell to arrange for another division of this part of the show. Heretofore the pleasure cars have been exhibited on the street floors of the two main halls with overflow exhibits in the balcony and basement. In order to keep the cars out of the balcony Manager Campbell plans to have a special pleasure car department in one end of exhibition hall basement. This department will have special decorations.

The motor cycle department that has been in the basement will be moved to Talbot hall, a large hall off the balcony of exhibition hall, and the café will be in the basement. The decorative scheme for the show is being worked out, but has not yet been fully decided.

DEATH OF GEO. T. BARNSLEY

Pittsburgh, Oct. 25—Geo. Thos. Barnsley, road engineer of Allegheny county, died Saturday of heart failure. Mr. Barnsley was an officer of the Automobile Club of Pittsburgh, and it was chiefly under his direction that the County Roads contest now being brought to a close, was started last February. He had one great ambition, namely, to get 600 miles of macadamized roadway in Allegheny county. Already he had accomplished more than one-half of this task, and his plans were well laid for completing the remaining 300 miles, which would make more than one-third of the county roads macadamized.

During the past ten years Mr. Barnsley has been a steadfast advocate for the kind of roads which automobilists like to see, and every effort which he could put forth to secure better facilities for the automobilsts of Pittsburgh was cheerfully given. He rendered splendid service in the sign campaign, and also in securing effective city and state legislation of benefit to automobile owners and users. His death has taken from Pennsylvania its most noted road engineer, and a man who will be greatly missed by automobilists.

Mr. Barnsley was forty-five years of age, and had always been a resident of Pennsylvania. He was a graduate of the Rensselaer Polytechnic Institute of Troy, N. Y. He served successfully as engineer with the Norfolk & Western Railway Co.; the Pennsylvania Lines, and as chief engineer of the Wabash-Pittsburgh Terminal System. He was elected road engineer of Allegheny county in 1906.

CONVERSE NOW MASSACHUSETTS LEADER

Boston, Oct. 25—The annual meeting of the Massachusetts State Automobile Association was held last Thursday evening in the rooms of the Bay State Automobile Association, with a fair representation of delegates of the different clubs. A. E. Bliss, president, was in the chair.

At the election of officers A. D. Converse, of Winchendon, the past year chairman of the legislative committee of the association, was chosen president for the coming year. John P. Coughlin, president of the Worcester Automobile Club, was elected vice-president, and James Fortescue, secretary of the Bay State Automobile Association, was elected secretary and treasurer. He succeeds H. M. Sawyer, of Worcester, in the secretary's position, and J. C. Kerrison, of Boston, as treasurer.

The association passed a vote of thanks to Mr. Kerrison for his work as treasurer the past four years and elected him a permanent member of the association. The headquarters of the association will be at 24 Milk street, Boston, the secretary's office.

Mr. Converse presented an exhaustive report of the Committee on Legislation, telling in detail of its work in connection with the new automobile law that was passed by the Legislature last session. The committee considers the new law exceedingly fair to motorists and advocates giving it a fair trial. W. H. Chase, for the Good Roads Committee, presented a report showing that his committee had not been idle. The report urged upon the constituent clubs more energetic action in the cause of good roads. It was reported that several new clubs have been formed in the State and will be admitted to the State association. The new officers also are planning a campaign to secure a large number of new individual members.

MOORE OF MILWAUKEE, WISCONSIN HEAD

Milwaukee, Wis., Oct. 25—M. C. Moore, of Milwuakee, is the new president of the Wisconsin State Automobile Association, and he states that he will work with the spark advanced and the throttle wide open. James T. Drought continues as secretary, and George A. West remains in the treasurer's place. F. P. Hixon, of La Crosse, is first vice-president, and H. L. Halverson, of Whitewater, is second vice-president. The executive committee ocnsists of: A. R. Barker, Portage; C. W. Norris, Milwaukee; A. J. Horlick, Racine; George A. West, Milwaukee; James T. Drought, Milwaukee.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers. Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows Building.

Jan. 21-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 21-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 19-26......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show. D. H. Lewis, Manager.

FOREIGN

Nov. 12-20.......London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

AMERICAN

Races, Hill Climbs, Etc.

Oct. 28-30........Dallas, Texas, Three-Day Track Meet, Dallas Automobile Club.

Oct. 30...........Vanderbilt Cup Race, Long Island Motor Parkway, Motor Cup Holding Company.

Nov. 6-8.........Phoenix, Arizona, Road Race, Maricopa Automobile Club.

Nov. 8-9.........Savannah, Ga., Georgia Highway Reliability Contest to Atlanta, Savannah Automobile Club.

Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.

Nov. 20-21.......New Orleans, Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary.

Nov. 22..........Denver, Col., Start of "Flag to Flag" Reliability Run. G. A. Wahlgreen, Manager.

Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

CARL FISHER BECOMES A BENEDICT

Indianapolis, Oct. 23—Carl G. Fisher, one of the best known automobile men in the West, was married to-day to Miss Jane Watts at the home of the bride's parents in North Capitol avenue. Following the ceremony, Mr. and Mrs. Fisher left for Chicago, and will go from there to California and Mexico for an extensive motor trip. Mr. Fisher has taken a house at 500 North Capitol avenue which they will occupy on returning to the city.

Mr. Fisher is president of the Indianapolis Motor Speedway Company; president of the Presto-O-Lite Company, and treasurer of the Fisher Automobile Company, as well as an officer and large stockholder in the Empire Motor Car Company.

What the Clubs Are Doing These Days

BOTH PHILADELPHIA CLUBS WANT HOMES

PHILADELPHIA, Oct. 23—One result of the success of the Quaker City Motor Club's efforts in connection with the Fairmount Park race is the revival of the agitation for a clubhouse. The thousands of out-of-town visitors were astonished to find that the club was housed in a three-room suite in the Hotel Walton, and even though all the comforts of a modern hotel were within call, the guests could not be welcomed with the freedom and lack of restraint possible in private quarters. E. H. Fitch, George M. Graham and Allen Shelden have been appointed a committee on ways and means, and are now considering the question.

The Automobile Club of Philadelphia, which has an even smaller suite across the street from the Hotel Walton, also has the clubhouse bee in its bonnet. With 955 members on the rolls, it looks as if this organization is in even better shape than the Quakers to undertake the responsibilities of a householder. Dr. D. Braden Kyle is chairman of the committee having the matter in charge. The club is continuing its efforts in the sign-boarding line, and its display of signs, maps and road books at the Cleveland Good Roads Convention drew much favorable comment.

CANADIAN AUTO CLUB MAY TAKE UP AVIATION

MONTREAL, Oct. 23—"The Automobile and Aerial Club of Canada" will be the future title of what is now the Automobile Club of Canada, if the directors' resolution to take up aviation as a joint sport is adopted by the members at the annual meeting. The directors met yesterday afternoon and enthusiastically endorsed a proposition to extend the club's sphere of activity in this manner; they see a big future ahead for the aeroplane, and are anxious that theirs shall be the first club to take up the sport in Canada.

George Husson, manager of the Franco-American Automobile Company, of this city, has for some time been in communication with Louis Blériot, and has been assured that he could easily learn to operate one of the Frenchman's famous monoplanes. He expects to sail for France in November, and will spend three months looking over the machines turned out by the big companies. Curiously enough, much of the wood used by Blériot and other aeroplane constructions comes from Canada. The spruce of this country is found to suit admirably for many parts of the machines. Mr. Husson expects to bring back an aeroplane with him and begin flights.

PENNSYLVANIA CLUB'S THIRD ANNIVERSARY

LANSDOWNE, PA., Oct. 23—Two hundred members and guests gathered to celebrate the third anniversary of the Automobile Club of Delaware County, Pa., last Wednesday. The election was perfunctory, last year's officers being again chosen, as follows: J. H. Weeks, president; W. P. Anthony, vice-president; Dr. F. Marshall Harvey, secretary, and J. E. Mitchell, treasurer. The reports of the secretary and treasurer showed a membership of 410, and a balance of $710.02.

PITTSBURGERS WILL REWARD ROAD SUPERVISORS

PITTSBURG, PA., Oct. 25—At a banquet to be given by the Automobile Club of Pittsburg on Saturday evening, October 30, prizes will be awarded to more than 20 township supervisors who entered its good roads competition last February. More than $300 will be given in cash prizes and each supervisor will receive an additional gift of $5. The competition was for the purpose of seeing which supervisor could make the most improvement in his district during the season.

WASHINGTON CLUB HAS TWO HUNDRED

WASHINGTON, D. C., Oct. 23—The spacious country home of the Automobile Club of Washington was the scene of a merry gathering of motorists to-night, the occasion being the first of a series of stag smokers that will be held during the season. The clubhouse was thronged and a very entertaining bill was provided by the house committee. Six applications for membership were received. The club now has 200 members, and President W. D. West is determined to swell the number to 300 by the time of the annual meeting.

NEW YORK STATE CLUBS UNITE TO REPAIR BRIDGE

AUBURN, N. Y.—Oct. 23—The opening to the public of the free bridge across the Seneca River is directly due to the enterprise of the Auomobile Clubs of Auburn, Geneva and Syracuse. The State refused to appropriate the money for the repairs necessary to make the bridge safe and Cayuga and Seneca counties would only furnish between them $400 of the $1,500 required. At this juncture the Auburn club stepped in, and aided by the clubs of the two neighboring cities, made up the remainder. The club itself gave $150, the Geneva and Syracuse clubs gave $100 each, and the rest was from private individuals. President S. C. Tallman, of the Auburn Club, was in charge of the work.

Free Bridge Over the Seneca River, Near Auburn, N. Y., Repaired by the Local Automobile Clubs

THE LATEST NEWS FROM TIRETOWN

Akron, O., Oct. 23—The increase in the capital stock of the Diamond Rubber Company, from $5,000,000 to $10,000,000, marks another step in the remarkable and rapid growth in the business of the company. The increase was made in the form of a stock dividend, and announcement was made that the company expects to pay 10 per cent annually on the doubled capitalization. In anticipation of the increase in capitalization, the stock climbed as high as 350, while in the panic several years ago it was as low as 95. The increase in capitalization was made at the annual meeting, when the old officers of the company were re-elected. The company increased its stock from $3,500,000 to $5,000,000 in 1907, when it took over the Bryant Steel Wheel & Rim Company.

A. H. Marks, vice-president of the Diamond company, last week accomplished the largest purchase of suburban land ever made here. He bought 30 acres just west of the city, for which he paid $91,000. The Diamond Rubber Company has decided to further increase its plant by adding two buildings, one to be six stories high and 371 feet long, with a width of 103 feet. The size of the smaller building has not been decided upon. The proposed larger building will add six acres to the company's floor space, and the building now under construction, which will be completed by January 1, will add another six acres.

The Goodyear Tire & Rubber Company began this week planning to more than double its tire output by January 1 next. The beginning of next month a night shift will be put on, and from that time on the plant will be run night and day. Vice-President C. W. Seiberling announced that by the end of this year the output will be increased from 600 tires to 1,400 and 1,500 a day.

The Diamond and Goodyear Tire & Rubber Companies have landed two of the largest individual tire contracts of the 1910 season. The former has secured a contract to furnish 28,000 tires to the Maxwell-Briscoe Company, and the latter an order for 10,000 sets, or 40,000 tires for the Buick Motor Company.

The annual meeting of the Northwestern Rubber Company, of Liverpool, England, was held in the offices of the Diamond Rubber Company here this week, resulting in the election of A. H. Marks as president; William Alex Smith, of Glasgow, as vice-president and treasurer. E. E. Buckelton, Liverpool, secretary and managing director. These, with O. C. Barber, of Akron, and Joseph Torrey, of Liverpool, are the directors.

WASHINGTON DEALERS ENLARGE

Washington, D. C., Oct. 25—In anticipation of the largest volume of business in the history of the industry in this city, the automobile dealers of the National Capital are enlarging their salesrooms and making additions to their lines.

The L. P. Dorsett Company is doubling the capacity of its salesroom and garage at Seventeenth and U streets, giving it storage space for 100 additional cars. This company, which has handled the Stoddard-Dayton and Babcock electric for several years, has taken on the Mitchell and the Empire.

Chas. E. Miller & Brother, Ford agents, are remodelling their salesroom on Fourteenth street.

The Overland Automobile Company has secured a permit for the doubling of its garage at 1215 V street.

The Dupont Garage Company, which handles the Lozier, Columbia and Detroit electric, has opened a salesroom at Thirteenth and G streets, in the downtown business section.

The Motor Sales Company has relinquished the agency of the Herreshoff, and has taken the Moon and Rauch & Lang electric.

The Newbold-Speedwell Company has been formed to handle the Speedwell and has secured quarters with the Warner Motor Company, at 1206 New Hampshire avenue. G. H. Covert has been made manager of the Warner Company, succeeding A. Parker Warner.

The Roman Automobile Company, of Philadelphia, has opened a branch store on H street, and will feature second-hand cars.

The Wilson Company has moved into its new salesroom and garage at 1333 Fourteenth street, and taken on the Hupmobile.

$1,000,000 ROAD—JERSEY CITY TO NEWARK

Newark, N. J., Oct. 25—When the date of November 9 was set for the reception of bids to complete the gigantic Plank road project the friends of the movement for a real highway between Newark and Jersey City felt one big step had been made.

This road project has been under way for years, the object being the replacement of the present apology for a road with an up-to-date highway worthy of the name. While the original plans called for planks as a surfacing material, similar to the present surface of the road, the latest idea is to build a road with one of these materials: Medina sandstone, wood blocks, or granite blocks. The one to be used will be determined by the joint committee from Hudson and Essex counties, which committee is in charge of the whole work.

Among the features of the road which are worthy of mention are the following: The road surface will be widened to 100 feet, of which width some space on each side will be given over to the Public Service Company for trolley cars, those on one side of the road running to New York and the others to Newark. There will be 28 feet of roadway running east and west, and two sidewalks each 21 feet wide.

Important in the list of changes which this will necessitate is the bridge which will have to be built across the Passaic river. Proceedings to condemn the necessary land along each side of the present roadway have already begun and in one very important stretch this additional width of land has been donated. This is between the Passaic and Hackensack rivers, and was given outright by the Hackensack Meadows Company.

Expenses of the road improvements have been agreed upon, the two counties affected bearing the burden in proportion to the benefit derived from it. Thus, Essex county, to which the highway will be the more important, will pay for five-eighths, while Hudson county will pay the other three-eighths. This is with the exception of the big bridge, of which the trolley company will pay 25 per cent., after which the remaining expense will be shared by the counties in the same ratio.

NEWS PICKED UP IN FACTORY CALLS

The Simplex Motor Car Company, Mishawaka, Ind., with facilities to build the entire car, tires and ignition excepted, is rushing the work on this year's model and adding to the plant for future increased output.

The General Manufacturing Company, Elkhart, Ind., with added facilities, has contracted to build transmissions, clutches and motors in a large way for several of the Detroit makers who were caught in the material famine now on. The company is just finishing five hundred motors for the International Harvester Company.

The Elkhart Motor Car Company, Elkhart, Ind., makers of the Sterling, with a large new plant, reports material slowly coming in, but from appearances the company will put out three thousand cars this year. President Sterling just closed with the California agent to deliver two hundred cars.

AUTO SCHOOLS OPEN FOR SIXTH YEAR

What is probably the largest automobile school in the United States, and certainly is the biggest in New York City, opens to-night. This is the automobile school of the West Side Y. M. C. A. located on West Fifty-ninth street. The sixth year of work will be formally ushered in at a meeting in the auditorium at which several addresses will be made. Among the speeches and speakers are: "The Automobile and Aeronautics," Augustus Post, secretary of the Aero Club of America; "An Illustrated Look into the Rural Future of the Automobile," J. George Frederick, editor *Printer's Ink;* "The Outlook of the Automobile Industry," Hon. C. Andrade, Jr., attorney for New York Automobile Trade Association; "The Auto Driver and the Policeman," William McAdoo, former Police Commissioner. New York City.

GEMMER STEERING GEAR IS MUCH IN EVIDENCE

VARIETY seems to prevail in styles and types of steering gear used in automobiles, and it is a liberal education to visit the plant of the Gemmer Manufacturing Company, at Detroit, and take time enough examining into the process to learn how the gears are made. This plant was originally fitted out to make the Gemmer steering gear, but as demands increased and different designers of cars expressed preferences for other types of gears for reasons that seemed good to them, the maker of the Gemmer bowed to the will of the purchaser, fitted out more completely, and to-day in this plant it is possible to procure in quantity any of the several types of gear for which there is a material demand.

In the meantime, according to President Hammond, of the company, the variety of demands on the part of automobile designers is a source of extra cost, complicates the situation unduly and deliveries are rendered much more uncertain, so that uniformity would be a boon to the industry and standardization is a crying need.

The plant, which has been considerably more than doubled in recent times, is substantially fireproof, the idea being to reduce the chances of defaulting on contracts from this cause, and the shop system is so contrived that good work, reliability and freedom from labor trouble are regarded as of the greatest importance.

Foundry Products Are Stored Up—Most of the gear housings are made of malleable iron and any one familiar with this situation will readily understand that there is great uncertainty attending the procuring of the same. To guard against a famine of malleable iron it is necessary to carry a year's supply ahead and much room is taken up in storing this class of material. In the same way, drawn-steel tubing is stored, practically on a basis of a year's supply, and, according to the experience of the company, it is not enough to place orders and fix the time of delivery. The material must actually be delivered, stored, and the actual cash outlay is therefore very considerable, none of which can be recovered until the steering gears are delivered to makers of cars from time to time agreeable to contract conditions.

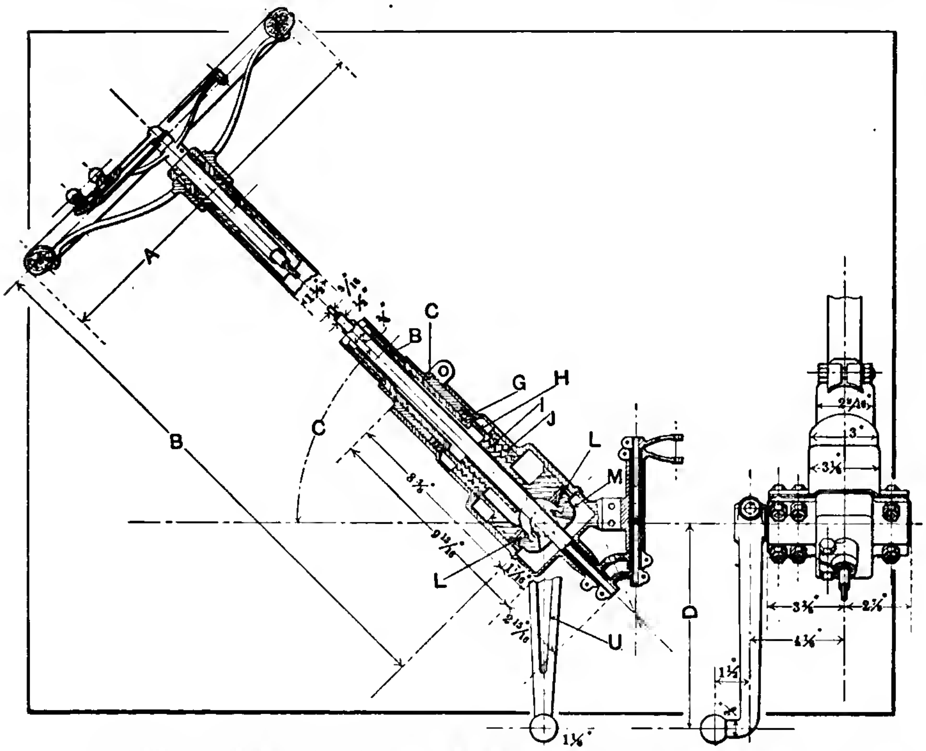


Fig. 1—Model C regular Gemmer Gear, showing bevel type of spark and throttle connections, mode of control, and well-designed steering arm

Shop Equipment Extensive and Complete—The several types of worms, sectors and other designs of gears are made of a free-cutting "cementing" steel, capable of being fashioned in automatic machine tools to the greatest possible extent, and special hobbing machines are employed in hobbing the worm threads. The parts are forged in dies, and in order to relieve strains they are annealed and otherwise prepared for the hobbing process. The above process applied to all of the types of worms and gears made, and after the hobbing is done and threads are cut, the worms and sectors are cemented and with a suitable depth of the carbon penetration as a result of cementing, they are water quenched to render the surfaces of the threads glass hard.

The class of material used is of such a high grade that water quenching is practicable, and the kinetic properties of the steel are assured by an intermediate oil-quenching process. In this way the worms and gears, without respect to type and price, are all of the same finish hardness and so uniform in structure as to leave nothing to be desired.

Regular Gemmer Gear Ranks as Standard—Fig. 1 depicts the regular Gemmer type of gear, the particular one being the Model C, and since the figure is in cross-section it will scarcely be necessary to discuss the working of the gear at great length. The first point to be readily disposed of is that of the concentric disposition of the spark and throttle rods; they pass up through the column to levers on the wheel and motion is imparted to the rest of the system by means of a bevel-gear system attached to the housing at the bottom end of the column.

The steering wheel may be of any desired diameter, the usual range being about 16 inches. The wood may be mahogany, black walnut or other selection and the manner of fastening the wood may be selected by the buyer with the understanding that the price will change accordingly.

Where the column is brazed to the gear a key is used as a safety measure so that, should the brazing fail, the key will have to be sheared off before the wheel will fail. That the key would shear off is not at all likely and the only thing that can happen is that lost motion might be developed, which lost motion would serve as a warning to the motorist that the brazing has failed and should be attended to.

This question of brazing, according to Mr. Hammond, is one that is in need of backing up by an independent safety measure on the ground that even a man of skill cannot be dead sure that the brazed joint is perfect and a separate key, in addition to brazing, affords a due measure of safety.

Principle of the Gemmer Gear—Referring to Fig. 1, the nut H has a right-hand thread outside engaging with nut J and left-hand thread inside engaging with nut I. When the wheel is rotated in one direction, thus rotating the nut H through the column B by the action of the right and left-hand threads, one nut is forced down against one of the pivot blocks L, depressing that side of the rocker shaft M and at the same time the other nut is raised. This action rotates the shaft giving the lever U its movement. Rotating the steering wheel in the opposite direction, the action on the shaft M moves the lever U in the opposite direction.

In view of the importance of adjustment of steering gear,

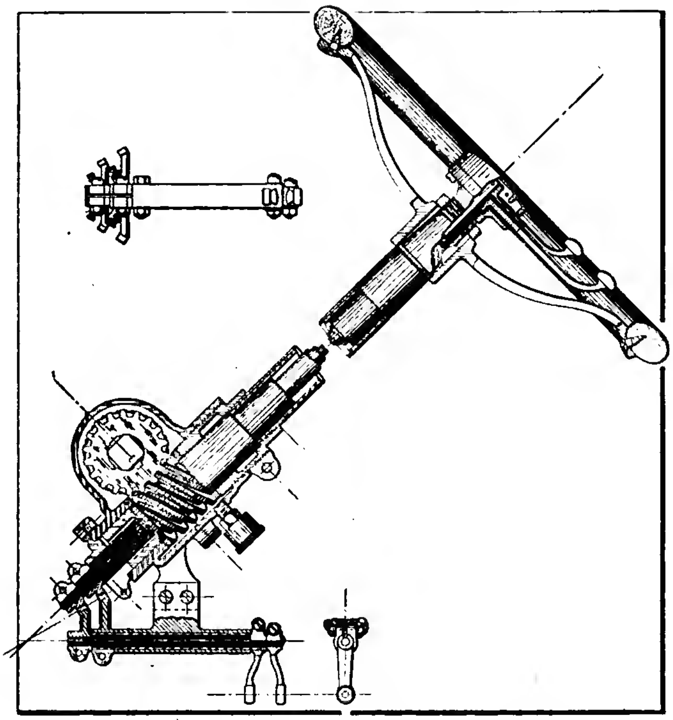

Fig. 2—A low-priced form of worm and sector gear with plain thrust bearings, but with means for adjusting

considering how very desirable it is to eliminate lost motion, it will be of advantage to notice that all the work done in imparting motion to the rocker shaft M is in compression. The nut J presses on one side, giving a movement in one direction and I presses on the other side, imparting the reverse movement. Under the circumstances the wear on the thread comes on one side only and if the adjusting nut C is screwed down to take up any lost motion there may be in ball thrust G, and continuing, presses on the nut H, which in turn pushes down against the nuts I and J, brings the bearing surface of the threads in contact and I and J in turn are pressed down against pivot blocks L and they against their bearings on the shaft M, thus eliminating lost motion at all points.

Shoulders will not form, as is bound to be the case in worm and sector types of gear, because in this type of gear any movement from the neutral point causes the wearing surfaces to overrun, hence shoulders are prevented from forming, so that after adjusting the mechanism will not bind.

Worm and Sector Types Are Much Used—From the Gemmer to worm and sector types is a considerable deviation, yet even so, a considerable part of the business of the company is that of building worm and sector types of gear, and Fig. 2 depicts the type C gear, which is the lowest priced product the company turns out. The work is keyed onto the spindle and a taper pin is fitted to a taper hole through the shell of the gear and the tube to prevent the worm from floating off. Bearings are of phosphor bronze, long and nicely fitted, and means are provided for adjusting the thrust surfaces up against the ends of the worm as the occasion requires.

In this class of worm and gear the quality of the material used is up to the customary standard of the company and the reduction in price is brought about merely by adapting the parts composing the gear to automatic machine tools, the use of plain but adjustable thrust bearings, instead of ball types, and in such other little economies as quantity production naturally falls heir to. The spark and throttle levers on this wheel as shown are different from those depicted in Fig. 1, but this is a matter which may be adjusted to suit the purchaser, who may choose any one of a number of systems available, paying the difference if there is any.

Fig. 3 shows the type K worm and sector gear, which is a more costly product than the gear shown in Fig. 2, primarily due to the use of a ball-thrust bearing and to such other little refinements as a difference in price will naturally support. This gear is used on cars weighing up to 4,000 pounds, is provided with a quadruple thread, 2-inch lead, six pitch, 5 1-2 to 1 ratio of worm to sector and the throw of the lever is 65 degrees per turn of the wheel. Special designs necessarily interfere with delivery, and are at extra cost. As a rule, quality is more dependable if regular designs are used.

Steering Wheels in Divers Forms—In some examples the spiders of the wheels are of bronze, but aluminum is the favored material. The spokes in each case are dished, internal strains are eliminated, and "wasters" are reduced to a minimum. The wheels shown in the figures are of the class with the wood work fastened on by means of screws, but in the finer examples of work in the Gemmer plant the wood is laminated, using mahogany for the purpose, and the lamanæ, after being built up and glued on to the flange of the spider, are finished.

The finish may be in natural mahogany, rosewood or any other style, and the character of the finish depends upon the amount of money the purchaser wants to pay. The strength of the wheels is not dependent upon the finish, and it is the claim of the maker that the wheels on the lowest priced gears are quite as safe and secure as the products with the highest finish.

RELATION OF GASOLINE VAPOR TO AIR

In any discussion of the relation of gasoline to atmospheric air, it becomes necessary to carefully distinguish as between vaporized and liquid gasoline. With air at 60 degrees Fahrenheit, about 15 per cent. of true gasoline vapor will produce a state of saturation. Such a mixture would be non-explosive, and in practice the following holds:

Volumes of gasoline vapor in per cent of air volumes	*Volumes of atmospheric air at 60° F. corresponding	
15.0		Saturation point of air at 60° F.
5.5	3,400	Too rich to serve for the purpose
4.0	4,000	Uncertain in its action
	5,000	
	6,000	
	7,000	
1.9	8,000	Suitable for the best results
	9,000	
2.4	10,000	Too uncertain to be of value

*In the above table the volumes of air relate to one volume of liquid gasoline, whereas the vapor volumes are in percentage of the air volumes used in each case. Absolutely accurate determinations will depend upon the mixture being of a definite character.

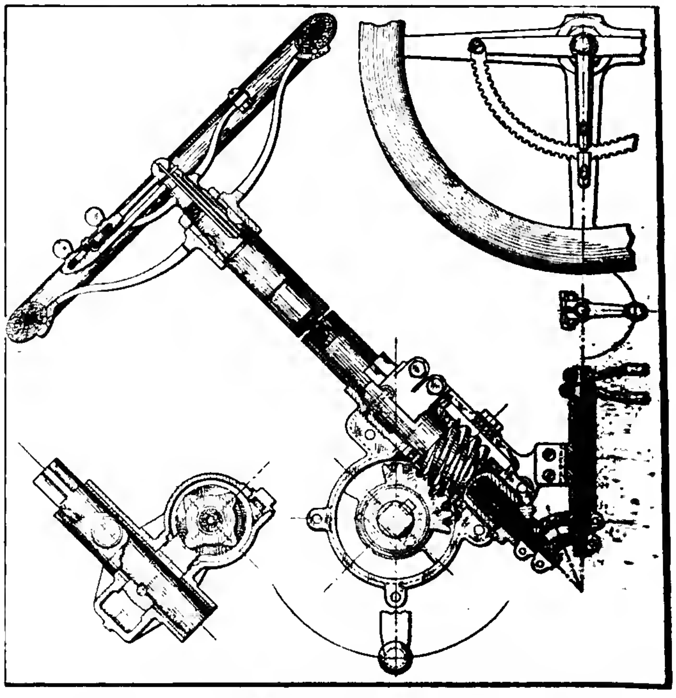

Fig. 3—Model K worm and sector gear with bevel spark and throttle, and ball-bearing thrust

IN AND ABOUT THE GARAGES

Pittsburgh—The Standard Automobile Company has let the contract for a four-story garage, 215 by 70 feet, at Grant Boulevard and Bellefield avenue. It will be finished in gray pressed brick and terra cotta, and the cost is estimated at $125,000. Plans are being prepared for a garage to be used by a new taxicab company at Grant Boulevard and Craig street. This will be four stories high and 135 feet square, and is to have one of the most complete repair shops in the city. At Butler, Pa., 30 miles north of Pittsburgh, the Atwell Automobile Company has broken ground for a $25,000 garage, two stories high, in which the Oldsmobile and Cadillac will be sold.

Philadelphia—The Regent garage, 4525 Springfield avenue, has recently doubled its storage capacity by the erection of another building, giving the largest unobstructed floor space of its character in the city. Its depth is now 227 feet and width 50 feet, and it is also remarkable from the fact that it has two six-foot skylights each 76 feet in length. There are now two entrances to the garage, the former one on Springfield avenue, and a new one from Baltimore avenue, so that cars may enter or leave from either street. Frederick K. Mears is the proprietor.

Gouverneur, N. Y.—F. N. Freeman, representing the Gouverneur Maxwell-Briscoe Motor Company, has just completed one of the finest garages in the State. It has been built to accommodate the great number of tourists, en route from southern and western points to the St. Lawrence, Montreal, and Plattsburgh. The floor space is 75 by 110 feet in size, giving space not only for the storage of many cars, but also for the repair shop, and a stock room with all kinds of general parts and accessories. A finely appointed women's waiting room is a feature.

Baltimore—A garage is being erected at Charles and Twentieth streets by the Dixon S. Walker Auto Company, agent for the Studebaker. The company's business has outgrown its garage at 1917 North Charles street, which was new only a year ago. The new garage will front 175 feet on Charles street, with a depth of 80 feet. Charles H. Evans has opened the Northeastern Garage, at Regester and Federal streets. The building has a capacity of 30 machines.

St. Augustine, Fla.—The St. Augustine Machine Company has arranged to build a large addition to its garage on Granada street. At present the quarters are 40 by 46 feet in size, and with the new part will be increased to 40 by 120. This will greatly enlarge the storage capacity and will also give space for a well equipped repair shop. The proprietors have also decided to increase the gasoline storage capacity to 500 gallons.

Pittsburgh—The E. J. Thompson Company has purchased a site on New Louisa street, near the world's biggest baseball grounds, on which to erect a garage. The property is 75 by 110 feet. A concrete garage to cost $50,000 will be erected.

New Fireproof Garage of Easton Auto Co., Easton, Pa.

Newark, N. J.—The Newark Auto and Engineering Company is building a salesroom and garage at 318-320 Broad street, north of Belleville avenue. The building will be 50 by 100 feet, of brick and steel construction with stucco front and one story high. The company holds the agency for the Rambler. Temporary offices are located at 151 North Sixth street.

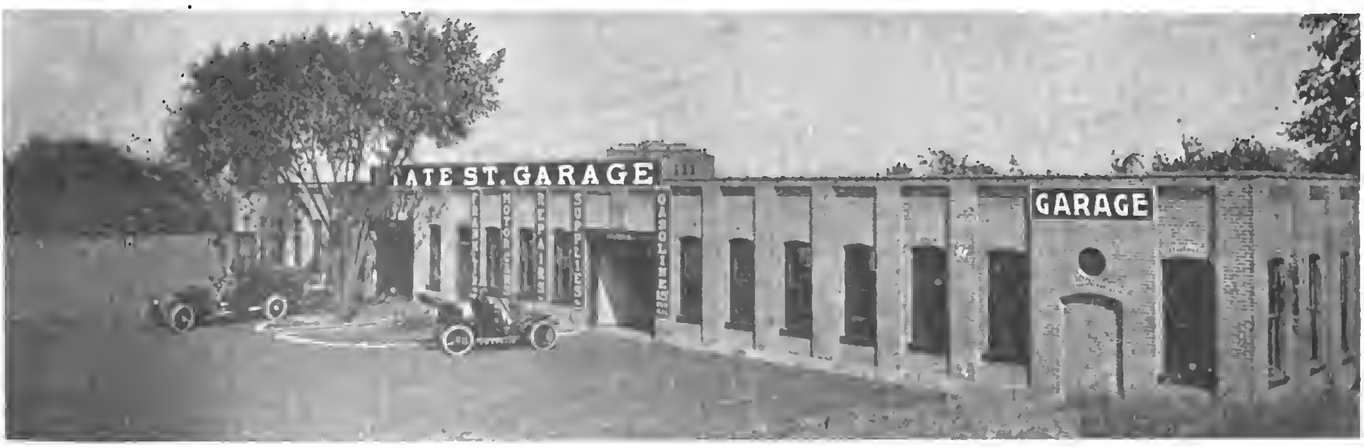
Augusta, Ga.—The communistic garage, proposed by President C. B. Garrett of the automobile club, is finding favor among local autoists. It is probable that no difficulty will be found in getting 30 men to subscribe $500 each for stock, and then the building will be erected. It is planned to have it centrally located.

Baltimore—The Ford Automobile Company has arranged to build a modern garage on West North avenue. The site is 40 by 110 feet in size and the building will be two stories high, with the lower for show purposes and the garage, while the upper will contain the offices and repair shop.

Valdosta, Ga.—Ground has been broken for a new garage by A. A. Parish. The location is at 116 and 118 West Central avenue, and the building will be 60 by 90 feet in size. It will be fully equipped with repair shop and features for caring for the cars on storage.

Cincinnati—The Evanston Automobile & Garage Company has been recently formed in Cincinnati, with headquarters at 3705 Main avenue. Charles Schiear, C. Roy Clough and F. T. Larson are the organizers, and the agency for the Velie and Hupmobile has been taken.

Columbus, Ga.—The Georgia Automobile Exchange has purchased a lot on Second avenue, and will start the erection of a $10,000 garage for its own use.



Garage and Salesrooms of C. W. Gray, Watertown, N. Y., Which Has Just Been Completed

This garage is one of the most complete establishments of its character in the northern part of New York State, and is the home of the Franklin agency for Watertown and vicinity. The ample floor space and interior arrangements make it particularly available for the expeditious handling of cars

A. G. Vanderbilt on Coaching Trip Uses White Steamer as Tender

On the recent trip of the New York Coaching Club from New York to Newport in Mr. Vanderbilt's coach "Pioneer," a White Steamer accompanied the party as "tender" and general utility and emergency wagon. The White was used to carry extra parts for the coach, for running ahead and making arrangements at the ferries, and for bringing news of the approach of the coach to the stations where the horses were to be changed. Occasionally, when it was necessary to lighten the load of the coach on a steep hill, four or five of the passengers would transfer themselves to the automobile

Pierce-Arrow Auto School.—As in former years, the Pierce-Arrow Company will conduct a free school of instruction, divided into three sections, for owners of Pierce-Arrow cars, drivers, and dealers and repairmen. Each class will last two weeks, beginning soon after the first of the year and continuing through the Spring. Two classes will probably be set apart for colored men. The classes for owners will contain more of driving instruction than the others, while those for drivers will be taken up largely with a thorough foundation in the care and maintenance of the cars. Dealers and repair men will be well grounded in the principles of construction and in the making of adjustments. Driving of the cars does not predominate in any of the courses, although it has a part in each. A six-cylinder 48-horsepower car will be used in the instruction school. No fee is charged, the only requisite being that the entrant be an owner, driver of or dealer in Pierce-Arrow cars, bearing a letter of identification from the dealer in his district.

Firestone Says 135,000 Cars—The published claims of automobile makers as to their productions during the coming seasons may occasionally need to be taken with a grain of salt, but the purchasing departments of those makers are not likely to order more tires than they can actually build cars. H. S. Firestone, who naturally has opportunities to obtain inside knowledge of the plans of the purchasing departments, conservatively estimates that the production for 1910 will be about 135,000 cars. Mr. Firestone also expresses a belief that one-third of the cars will leave the factories with demountable rim equipment.

Prospects at Peru, Ind.—The Peru Auto Parts Mfg. Co., recently organized at Peru, Ind., with a capital of $200,000, has purchased a $60,000 plant on the lines of the Wabash and L. E. & W. railroads and will begin immediately the manufacture of automobile wheels, axles and other parts. The officers of the company are S. H. Penfield, president; John Tomey, vice-president and treasurer, and Frederick Brown, Jr., secretary. It is reported that this company is distinct and separate from the Salisbury Wheel & Mfg. Co., of Jamestown, N. Y.

For More Breeze Carbureters—The Breeze Carbureter Company, of Newark, N. J., is building a reinforced concrete factory on South street, Newark, which will afford about ten times the floor space of the company's present quarters. The equipment will be the most modern throughout, including fireproofing and sprinkler systems. Pressure of business has necessitated moving the company's offices from the present factory at 276 Halsey street to 14 William street, the space vacated by the office being devoted to manufacturing.

Grout in Suburban Service—George H. Prouty, of Barre, Mass., has put in service a nine-passenger Grout between Petersham and Barre, carrying passengers and mail. The car has three seats, seating three passengers on each, and is finished with unusual elegance, considering the service in which it is used. Its maximum speed is about 30 miles an hour. Mr. Prouty expects to put a 12-passenger car in operation soon.

New Maxwell Branch at Albany, N. Y.

Ohio Electrics at Toledo—The stock of the Ohio Electric Car Company has all been subscribed in Toledo by twenty capitalists of that city, each taking the maximum of $5,000. The office and works of the new company are located at the Milburn Wagon Company's plant and a large force of men is already at work there on the bodies. One type of electric chassis will be built.

Big Ball Bearing Order Placed—From the J. S. Bretz Company, with offices in the Times Building, New York City, the E-M-F Company has ordered 20,000 F. & S. ball bearings for 1910 cars. These are to be used on the main driving pinion for live rear axles, and are arranged for both thrust and radial loads.

NEW YORK TRADESMEN ENERGETIC

For some time past, members of the New York Automobile Trade Association have not been entirely satisfied with the work of the organization, and the subject received considerable attention at a recent midday luncheon, held at the Hotel Cumberland, on Broadway, and presided over by Gen. John T. Cutting, twice-elected president. A committee was appointed to revise the present constitution and by-laws, which have not enabled the association to enlarge its scope to meet changing conditions. President Cutting advocated greater interest in metropolitan automobiling.

Among the other association members who spoke were: C. Andrade, Jr., of the R. M. Owen Company; J. F. Plummer, of the Locomobile Company; Robert Slusser, of the Harrolds Motor Car Company; W. W. Burke, of the Mora Motor Car Company, and C. W. Wurster, of Wyckoff, Church & Partridge.

NEW MAXWELL BRANCH AT ALBANY

The Maxwell-Brisco Motor Company has opened a branch at 72-74 Central avenue, Albany, N. Y., where it has one of the finest show rooms in that portion of the Empire State. W. K. Hadley, a veteran in the automobile field, has been appointed manager. He has been connected with the sales department of the home company for the past three years in a traveling capacity.

IN AND ABOUT THE AGENCIES

Pennsylvania Agencies—The following agencies are announced by the Pennsylvania Auto Motor Company, Bryn Mawr, Pa.: Middleton Motor Car Company, 548 Golden Gate avenue, San Francisco; Vail Motor Car Company, Los Angeles, Cal.; Lemly-Mills Auto Company, San Antonio, Tex.; Pennsylvania Sales Agency, Atlanta. Ga.; D. A. Kendall Motor Company, Kansas City, Mo.; H. Weston, Jacksonville, Fla.; Pensacola Buggy Works, Pensacola, Fla.; Pennsylvania Selling Agency, Providence, R. I.; Murray O'Neill, New Bedford, Mass.; Haynes Automobile Company Minneapolis, Minn.; Oliver De Charme, Troy, N. Y.; Philip A. Lowe, Pittsfield, Mass.; C. W. Fulkerson, Carbondale, Pa.; Pennsylvania Selling Agency, 609 Neville street, Pittsburgh; Walter Slack, Trenton, N. J.

Winton, Philadelphia—Manager A. E. Maltby, of the Winton branch at Philadelphia, has decided to rebuild on the site of the present building at 246 North Broad street, the specifications calling for a two-story structure with a floor space of 25,000 square feet. The first floor will be occupied by showrooms and offices and the second by shops, stock rooms and storage. Pending completion, which cannot be before March 1 next, the Winton agency will be in temporary quarters at Broad and Race streets.

Packard, Philadelphia—After November 1 the Packard, for many years represented by the Keystone Motor Car Company, will be handled direct from the factory through a branch house. Just who will be the head of the branch has not been announced. It is understood, however, that the establishment of the Keystone Company, on North Broad street, will be bought outright.

Bosch Magnetos, San Francisco—The Bosch Magneto Company has established a branch at 537 Van Ness avenue which is to be its headquarters for the West and the Pacific Coast. A stock will be kept of the various types of Bosch magnetos and their fittings and parts, and the new branch will be conducted in the same manner as the New York main office and the Chicago branch.

Continental Tire Agencies—Additional distributing agencies of the Continental Caoutchouc Company are the Gibson Automobile Company, 238 Massachusetts avenue, Indianapolis, for a part of Indiana; the Jas. S. Bailey Company, Portland, Me., and the Auto Supply Company, Baltimore, for the entire State of Maryland.

National and Standard, Omaha, Neb.—The Standard Automobile Company, composed of H. E. Wilcox and Charles Merz, who is to drive a National in the Vanderbilt, is building a garage on Farnam street, west of Twenty-fourth, where it will sell National and Standard Six.

Jackson, Philadelphia—S. R. Blockson has been awarded the agency for the Jackson, which he formerly handled with much success at Pedricktown, N. J. He will be with the Stoyle-Vogel Company, Broad and Race streets, until he secures permanent quarters.

Royal Tourist, Minneapolis, Minn.—I. A. Thorson and E. G. Johnson have organized the Royal Automobile Company to represent the Royal Tourist, with an office at 717 Hennepin avenue.

Assembly Floor of the Chalmers-Detroit Motor Company, Detroit

The entire second floor of the new building of the Chalmers-Detroit factory is used for assembling finished cars. The above picture shows one section of the floor containing chassis waiting for bodies to be fitted thereto, and the final touches applied before testing and shipment

American and Moon, Omaha, Neb.—The recently incorporated Sweey-Edwards Automobile Company will handle the American and Moon and expects to be installed in a new garage on Farnam street by December 1.

American Simplex, New York City—S. J. Wise has been appointed metropolitan agent for the American Simplex and has established headquarters at Broadway and 54th street.

Acme, Pittsburgh—L. Glesenkamp, Sons & Company have secured the Acme agency, and will also handle the Glesenkamp-Martin commercial car, a local production.

Baker, Wilmington, Del.—Col. G. P. Postles, who is the agent in this city for the Chalmers-Detroit and Hudson, has taken the representation of the Baker electric.

Kline-Kar, San Francisco—The Frank O. Renstrom Company, of 424 Stanyan street, opposite Golden Gate Park, has taken the agency for the new Kline-Kar.

PERSONAL TRADE MENTION

A. D. Frost, formerly sales manager of the Harry S. Houpt Company, New York City, in which capacity he had charge of the distribution of the 1909 Herreshoff, has been appointed sales manager of the Herreshoff Motor Company, of Detroit. The 1910 Herreshoffs will be marketed direct from the factory.

William F. Horner, resigning from the automobile editorship of the New York *Press*, has taken a similar position with the Brooklyn *Eagle*. William Newton, formerly of the *Eagle*, succeeds Mr. Horner on the *Press*.

H. W. Doherty, sales manager for the Cameron Car Company, Beverly, Mass., for the past two years, resigns his position with that company November 1. Mr. Doherty has not announced plans.

William J. Urquhart has been promoted to be general manager of the Western sales department of the White at Chicago. C. A. Hawkins will devote attention to Pacific Coast sales.

Rapidly Developing Plant of the Chalmers-Detroit Motor Company at Detroit

The photograph shows some of the additions now under way. To the extreme right is shown the old factory building, while in the center is the recently completed addition. To the far left is the first floor of a contemplated four-story duplicate of the other two main buildings. Additional floors are now being added to the original building as well as the completed new building

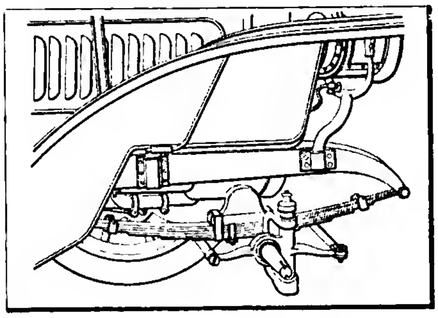
Information for Auto Users

High Compression Spark Plug—In the construction of the Champion spark plug, the makers, the Champion Company, 36 Whittier street, Boston, use great care and the best of materials, so that the resulting plug is particularly suitable for cases where the duty is severe, as for use with high compression, with excess of oil in the cylinders, with magneto, etc. In fact, as to magneto, the makers say that this plug is particularly suited for that use, since the nickel-alloy points used are imperforable to spark of any intensity. Under the severe use demanded from a magneto plug, they will not burn off. One point

CHAMPION PORCELAIN SPARK PLUG

of sterling worth is that the center wire is firmly cemented and baked into the porcelain forming the central portion of the plug. This also prevents any possible leak of cylinder compression through that opening. Both shell and bushing are cut from solid stock, so that the porcelain does not contact with either.

Trailing Axle Spindle Makes for Safety—Since the public is always interested in any device which makes for increased safety without complicating the machine or materially increasing the cost, a short description of the principles and action of the B. & L. Front Axle Trailing Spindle will be of interest. This device is made by the Queen Mfg. Co., Webster City, Ia., and is intended primarily to be a safety device—a sort of life insurance. The axle spindle is set back of the center of the front axle by a predetermined amount, this setting back or offsetting resulting in the spindle, and with it the wheel, following a straight-ahead line, whether the cross-connection be severed or not. Thus, in case of an accident which breaks or loosens the cross rod, the car will continue straight ahead, regardless of that fact. It is claimed that, strictly aside from this safety feature, the car equipped with this trailing spindle, steers so much easier as to eliminate all fatigue from that cause. As proof of their claims, the manufacturers, who now have shop rights for sale, claim to have driven a machine thus equipped through eight loads of



B. & L. TRAILING FRONT AXLE

sand so distributed as to strike only the wheels on one side, this being done at a speed of 25 miles an hour, and without the hands touching the steering wheel. On this test the car did not vary 6 inches from a straight line.

Self-Adjusting Tire Tread—For the season of 1910, the Leather Tire Goods Company, now located at Niagara Falls, N. Y., have brought out a new style tire which will be welcomed by tourists who who have known and appreciated the Woodworth Adjustable Tread. The newer form differs from the old in the method of fastening the tread on the tire. The tread itself consists of a number of galvanized steel plates riveted along each side of the tread a short distance apart and connected by short, stiff

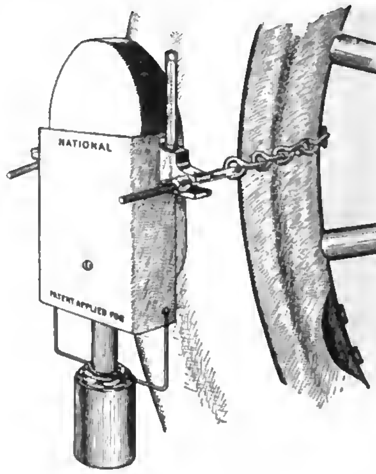
WOODWORTH SELF-ADJUSTING TREAD

springs. Each spring is linked to one end of a plate and has a hook at the other end. The tread is applied by slipping it sideways over the deflated tire with the springs unhooked. When in place, the springs are hooked into the plates, forming a ring around each side. As the tire fills out, the springs are stretched, holding the cover tight on the tire and ready to take up any slack.

More than this, the leather used in the new treads is treated by a new process, which the makers state doubles the life of the leather, preventing the action of dirt and water from affecting it. The new leather is of a dark green color.

The rivets used in this tread have thicker heads, thus adding greatly to the mileage obtainable. The corners of each rivet are rounded off so that they cannot be caught in such a way as to be forced out of the leather. More, the leather on each side of the heavy rivet is studded with smaller, flat-headed rivets, which, while adding little to the total weight, protect the leather in ruts, or on rocky roads.

New Small Vulcanizer of Simple Form—With the usefulness of a vulcanizer admitted and fast becoming well-known for its economical effect upon tire upkeep, there is a wide demand for a small and portable machine as opposed to the very expensive large ones, which are heavy and bulky to handle. The newest to appear is that of the National Motor Supply Company, Cleveland, which is called the National steam vulcanizer. This is a small device consisting of a brass shell, which is filled with water.



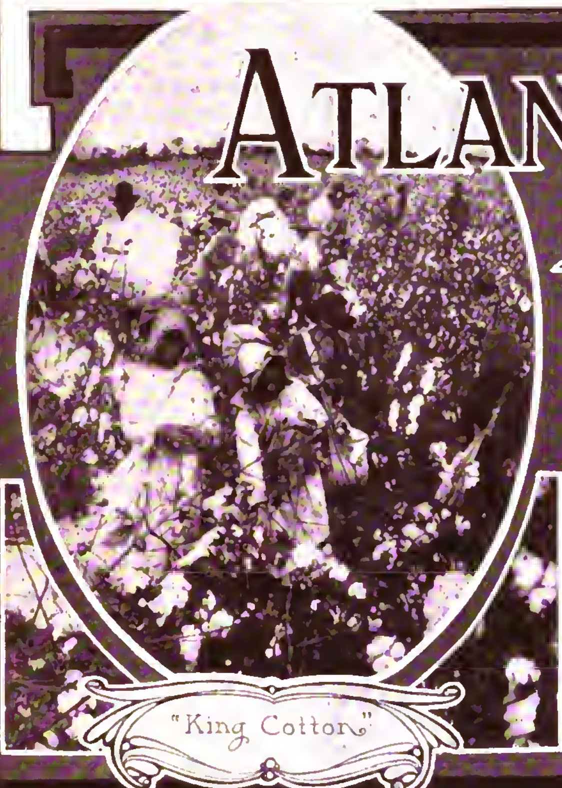
NATIONAL VULCANIZER IN PLACE

This shell may be held to the tire by means of small chains and screws with wing nuts to regulate the tension. In this way, the vulcanizing may be done right on the tire, allowing the use of the device out on the road if so desired. In addition, there is a small alcohol lamp or torch attached to the base of the brass shell, which is utilized to heat the water. This water is heated to such an extent as to turn it into steam, when the action of the vulcanizer proceeds just the same as any steam device. The size of the torch is such as to turn the water into steam in about 7 minutes, and a complete job in less than 15 minutes.

Aside from this, the National is very simple to operate, as there is nothing to get out of order. The flame guard is interchangeable from one side of the vulcanizer to the other, so that the flat side can be used for tubes and the concave side for shoes. A complete outfit is furnished, and since there is no danger of burning or otherwise injuring the tire, it makes a very efficient outfit for the private owner.

THE AUTOMOBILE

ATLANTA THE AUTO MECCA OF THE SOUTH



"King Cotton"

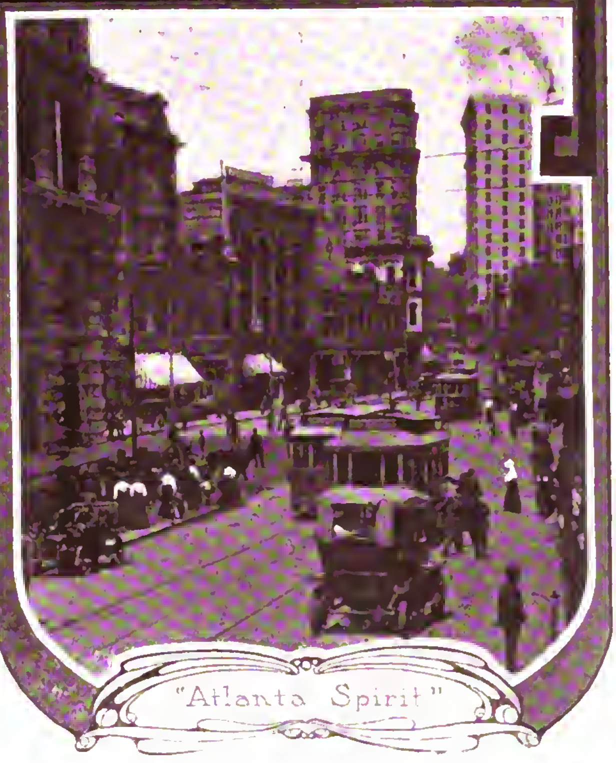
ATLANTA, GA., Nov. 3—This "Gateway of the South" in another day will have become the "Autoists' Mecca," with a plenteous vanguard already in possession of the liveliest city of the New Southland, which values to the greatest extent the boon of the motor-driven vehicle that abridges distance and spells economy and cements the bonds that unite all sections of the country.

The big Auditorium-Armory is crowded with the 1910 products of the American automobile manufacturers, and the display tells a story that will be concluded as the salesmen write down the orders which must be the inevitable result of such a choice auto menu. Managers Miles and Reeves, two past masters in the show line, have done their work thoroughly and artistically, aided, of course, by a capable committee from Atlanta's progressive citizenship. The mammoth building lends itself to exhibition purposes, and this will be apparent to the thousands when on Saturday they are allowed to feast themselves upon the inviting up-to-date demonstration of the greatest and most beneficial industry of modern times.

Over the roads the visitors are coming Atlantawards, the New York-to-Atlanta good roads tourists being the earliest arrivals, after having created excitement and enthusiasm all the way from the Big Town of the country. When men get together they are certain to talk and discuss, and the result invariably is action of some kind. To realize how greatly the South is interested in good roads, one has only to broach the subject these days, and then he will discover that the building of real highways is something that finds pronounced favor with a section of the country which is only awakening to its possibilities.

All Atlanta autodom and most of the South is patiently engaged in holding its breath in expectation of the very, extremely large, doings during "Auto Week," the greatest motor celebration ever held in the South and one which in many ways is unique in all motor car history.

The New York-to-Atlanta tourists to-day found awaiting them a reception that is a wonder, in a quiet, artistic way. Some weeks ago



"Atlanta Spirit"

PHOTOS FROM STEREOGRAPH COPYRIGHT, BY UNDERWOOD & UNDERWOOD, NEW YORK the Atlanta Chamber of Commerce met and appointed committees to have the welcoming celebration in charge. Committees were named from the Capital City club, the Piedmont Driving club, and a committee to arrange escorts, and when these bodies got through their work it was certain that the tourists would be met in proper manner and entertained well upon their arrival.

Saturday afternoon the South's long-expected "Auto Week" actually begins—a "week" that stretches over some eight days, into which will be packed more automobile excitement than was ever before seen in this section of the country, and which, for variety of program, number of participants, and enthusiasm has seldom been equalled in America. 'Tis a full program.

Saturday night the show will open and run until November 13. Monday, from four Georgia cities, endurance runs will start, with Atlanta as the destination; and the following day a fifth one will get under way. Each run will consume two days. The Georgia Good Roads Automobile Association is engineering these: From Savannah, by the "Capital route"; from Fitzgerald and Albany, a run with two starting points, the contestants to meet at Macon and go to Atlanta in a body; from Augusta; and from Birmingham, in Alabama.

The Savannah run naturally promises to be the most important, for Savannah has a wholesale way of doing things that makes for success. Fifty starters from Savannah are regarded as probable. The list of entries heads off with Mayor George W. Tiedeman; F. C. Battey, president of the Savannah Automobile Club; Harvey Granger, and A. W. Solomon, names familiar in the arrangements for the Savannah race, and T. A. Bryson, who drove the scout car from Savannah to Atlanta and back.

The Albany-Fitzgerald run should be numerically strong, for Albany talks of fifty cars and Fitzgerald of thirty. Both cities have good entry lists already, headed in each case, as was Savannah's list, with the mayors of the cities. The first day that the entry blanks were out in Augusta a dozen entries were made for that run, so there will be a goodly number on hand before the entry lists close.

While the show preparations were going on the last finishing touches were put on the new automobile tracks, on which a meet will be held, November 9 to 13. The street car company has finished its extensions to the course, the railroads which reach the track have planned special schedules, and every inch of the main highway from Atlanta to the track has been oiled, in order to insure dustless running to the new course, as well as on it.

The day the first quartette of runs ends, November 9, will open the races. These will run for five days, giving the Southern city the longest track meeting ever known in America.

Representatives of the Atlanta Automobile Association were at the Vanderbilt Cup race, and straightway signed Hugh Grant, with his Alco; Joe Matson, with his Chalmers-Detroit; and Harroun, with his Marmon, which guarantees three recent winners on the Atlanta track. Strang had previously been landed, with a Fiat; as had Robertson with his Fairmount Park car. Louis Bergdoll will bring his Benz racer, and Kilpatrick will be on hand with his Hotchkiss. It is reported that Christie will be in Atlanta. Chevrolet, with his Buick, and the National team are certain starters. Other entries are: Hearne, Fiat; Basle, Renault; Cliquot, Pope-Toledo; Behr, Renault; the full Chalmers-Detroit teams; Grant, Marion; three Maxwells, two Mathesons, three Pullmans and one Moon.

N. A. A. M. Atlanta Show Committee

Of course, there will be a good many local entries from Southern branches and agencies located in Atlanta and the amateurs are likely to have some good races. As there are to be five full days of racing, each day's events to begin at 11 o'clock and to last until well into the afternoon, it will take a pretty good bunch of entries to make a go of the affair, but it is probable that plenty of cars have been secured.

Reports from the local committee are that there is an unprecedented demand for hotel accommodations, and to meet this demand requests for rooms will be referred to the Committee on Information and Public Comfort. Secretary George H. Chapin has issued application blanks for hotel accommodations and all such matters should be referred to him for attention. A circular issued by the committee says:

"The Committee on Information and Public Comfort undertakes to find comfortable rooms and board for prospective visitors to Atlanta during automobile week. It will, if possible, secure quarters in some of the hotels. If this is impossible, it will assign rooms in some of the best boarding houses or private homes, notifying the visitor immediately of the place selected, rates, and all other information. This will give the visitor opportunity to write to the hotel, boarding house, or householder and make what further arrangements may be necessary. The committee urges that all arrangements shall be made at once, as there will be many thousand visitors in Atlanta during automobile week and those who apply first will get the best accommodations."

Secretary Chapin also states that for parties touring to Atlanta it may be possible to secure a stopping place where automobiles may be stored.

HOW ATLANTA GOT A NATIONAL SHOW

By CLARK HOWELL, Editor of the Atlanta Constitution.

YOU ask me to tell you "How Atlanta come to get the first national automobile show of 1910 models?"

I will give you the facts in the case, and your readers may judge for themselves how it was done.

Somehow or other Atlanta has always been impressed with the fact that it was the center, or at least of this part, of the universe, and the "Atlanta Spirit" is proverbial.

It was created out of the ashes of the burned town left by General Sherman in 1864—then a place of about eight or nine thousand inhabitants. It had been the storm center of the Civil War, and was the last stronghold and gateway of supplies of the Confederacy. When Sherman took it and established it as his Southern base, the war was practically over. It did not take Appomattox to write the finale. The Confederacy fell with Atlanta.

Thousands of exhausted and impoverished Confederate veterans, moving backward and forward through the South to their depleted homes, passed through the town, which had been burned less than a year before, and observed on every side remarkable evidences of thrift and enterprise in the rebuilding of the place which had been only a few months before completely annihilated. It was with difficulty that enough workmen could be engaged in sufficient quantities to meet the demand. Supplies could not be obtained fast enough.

Many families in the county surrounding who had lived in opulence and ease as slaveholders before the war, and who, with the exception of their land, were left penniless at the end of the war, soon found new avenues of wealth in supplying brick and lumber and building material generally at unprecedented prices. Hundreds of the returning Confederate veterans from other States took advantage of the opportunity to get work and enter business anew.

Many of those who thus took up citizenship in the rebuilding town afterward became the most prominent and successful of the business men of the city, some of them laying the foundation of large fortunes afterward accumulated.

Other Southern cities did not recuperate from the devastating results of the war as rapidly as did Atlanta, and it was the remarkable energy exhibited by the city at that time that gave birth to the "Atlanta Spirit."

The Atlanta Show Committee

From that day to this Atlanta has been growing by leaps and bounds, stopping at nothing, aspiring to anything and accomplishing results which would often have staggered a city of ten times the population.

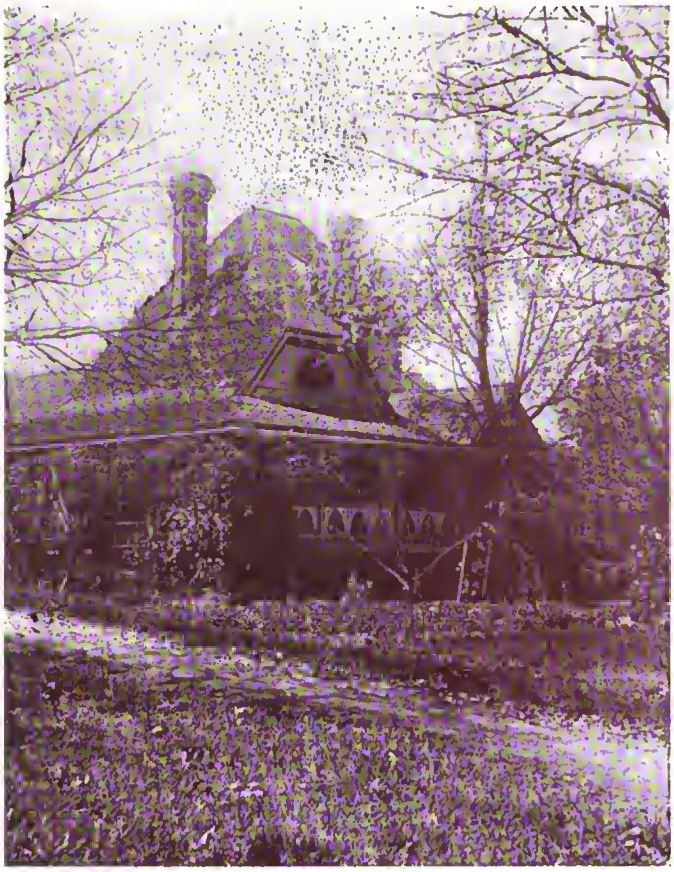
And that is why Atlanta went out after the first National automobile show of 1910 models.

We were aware of the fact that only two National shows were authorized by the National Association of Automobile Manufacturers—one at New York and the other at Chicago—and that numerous applications had been made by other large cities the country over for the authorization that would put them on the same basis as New York and Chicago.

Why not Atlanta, therefore, even though all the other aspiring cities had been turned down and had been told that it would be impossible for them to get anything more than a "dealers' show," which had been successfully conducted in Boston, Pittsburg, Cincinnati, St. Louis, Denver, San Francisco, and a host of other cities, without in any wise involving the National association, or committing it to a responsibility which it was unwilling to assume beyond New York and Chicago.

So we were told to go right ahead and arrange for a "dealers' show"—that we would have the best wishes of the National association, but that none of the manufacturers could exhibit unless their local dealers saw fit to do so, which, it was suggested, could very easily be arranged by the co-operation of the local dealers themselves.

The first suggestion of a National automobile show for Atlanta had been made through the columns of the Atlanta *Constitution*, which editorially took the position that as Atlanta was the commercial center of the great section represented in the South Atlantic and Gulf States, and as the natural crossing point of travel to and from all this section, it should stand for the South just where New York stood for the States in the East and Chicago for the West, and that if the automobile industry could be impressed with the wonderful possibilities of Southern development and the advantage of Atlanta as the distributing center of the Entire South, the National association could be induced to make an exception in Atlanta's favor and put it upon the same basis as the other National shows.



FROM STEREOGRAPH, COPYRIGHT, BY UNDERWOOD & UNDERWOOD, NEW YORK

Once the Home of Joel Chandler Harris

So it became a question of a National show or nothing'

A committee of seven was appointed to take the matter up with the executive committee of the National association, and I happen to know of the spirit that actuated that meeting and of the result obtained, for I was one of the seven, and my colleagues did me the honor to make me their spokesman.

We had an engagement to meet the executive committee at the association's headquarters at 7 East Forty-second Street, in New York City, and before the meeting almost every member of the committee in casual conversation had endeavored to pave the way for a soft place to receive our fall, preparing us in advance to meet the disappointment which they felt was coming.

But Benjamin Briscoe, the Maxwell king, a member of the committee, had chanced to be in Atlanta only a few weeks before and had seen the magnificent Auditorium-Armory Building, which had just been constructed by the city, and had had an opportunity to observe some of the "Atlanta Spirit."

"Boys," said he to the Atlanta committee, "those fellows are perfectly honest in their belief that it would be an unwise thing to authorize a National show for Atlanta, and they think they are not going to do it. But if you make the showing to them that you have made to me, and if they can be made to understand the situation as I have seen it, you will get the show."

The meeting occurred during the first week in May of the present year, and to make a long story short Atlanta got the first National show for 1910—to be followed by the National shows in Chicago and New York—these three cities being the only three whose shows are conducted under the auspices of the National association and at which exhibits are made direct by the national manufacturers of cars and accessories.

Incident to and built around the Automobile Show are various automobile attractions, such as the Speedway contest to take place at the $250,000 autodrome on the suburbs of the city; the State Good Roads Automobile contests from Augusta, Savannah, Albany, Fitz-Gerald, Dublin, and Birmingham, all centering in Atlanta, and the New York-to-Atlanta highway contest, all of these taking place during Automobile Week, which will begin November 6 and end November 13.

These varied automobile attractions have literally centered the interest of the automobile world on Atlanta, and every indication points to the fact that from the standpoint of the automobilist and the automobile industry, the week will be one of unprecedented interest in the annals of the trade in this country.

And just now the South, being at the top notch of prosperity with 13 1-2-cent cotton, will meet the trade more than half way.

The farmers of the State of Georgia alone will realize in cash this year $100,000,000 from their cotton, not to speak of the many more millions that will come from the manufactured goods and the by-productts.

It seems that the South has entered upon an era of unprecedented prosperity, and that the problem of the country people moving to the cities is being solved by automobiles, telephones, and good roads, bringing the schools within convenient reach of the farm house, and opening up facilities which have heretofore been denied the country home.

And the day is coming when every successful farmer will own his automobile—for he needs it even more than his city neighbors. What's more, he is able to pay for what he wants.

AUTOMOBILE SITUATION "DOWN MOBILE"

MOBILE, ALA., Oct. 30—The motor car situation in Mobile is one which holds out the greatest of promise. A city of upward of 70,000 people, having attained this growth mostly during the past six years, with large office buildings growing, it has paid little heed to motoring until recently. At the present time the number of cars taxed and recorded in the office of the city tax collector is 153. The majority of this number was bought during the past two years.

STRUCTURAL TENDENCIES IN ATLANTA EXHIBITS

DETAILS now form the field of the investigator in automobile design, and points which a few years ago would have been passed over unnoticed are now subjects for scare-heads. But there are two marked tendencies at present which are worthy of far more attention than they have hitherto received; namely, the abolition of the water pump and the similar fate of the spark-advance lever.

Thermo-syphon circulation, more familiarly known as natural circulation, has had a limited adherence from the earliest days of the industry. Renault and Brasier, of France, have employed it with the greatest success, even on their racing cars which won the Gordon Bennett and the Grand Prix. In this country Maxwell has always been a firm believer in this simpler method. Until quite recently, however, its spread has been slow. Now Brush, Elmore, Ford, Hupmobile, Jackson and Moline, as well as the pioneers, Maxwell and Renault, and the happily named "Billy" of local production, all appear with pumpless motors.

Although there has been no such unanimous movement against the spark-advance lever, yet the handwriting has appeared on the wall. This reform, too, was inaugurated by the French pair, Brasier and Renault, and by the Italian Fiat. Its principal American exponent has been the Franklin. Magneto ignition has made the fixed spark capable of universal adaptation, and its use offers many advantages in simplicity and economy.

TABLE OF SPECIFICATIONS FOR 1910

Structural details and dimensions of the gasoline and steam pleasure cars exhibited at the Atlanta Show are listed in the preceding tables. Owing to the earliness of the season, the information about some of these cars remains scanty, and consequently in many items the tables are incomplete. They will, however, suffice to give an idea of the number and quality of the exhibits at this first National show of the South.

Many of the manufacturers have given special attention to Southern peculiarities in respect to wheel tread. The wagons and carriages which use Southern roads almost invariably track 60 or 61 inches, and consequently the ruts are spread too far apart to suit a car with standard tread. For this reason a large percentage of automobile manufacturers make their cars with an optional width of tread of 60 inches. Such cars are indicated in the tables with an asterisk (*) placed against the regular figure for tread or wheel track. Many other makers whose cars are not so marked will supply the Southern standard for a slight extra charge.

A. L. A. M. Formula Rating Employed—The horsepower ratings are in all cases according to the A. L. A. M. formula, disregarding the makers' figures whenever these differ from the standard. It will be obvious that this is the only fair method of comparison. Some makers rate four five-inch cylinders at 30 horsepower, others at 50; the difference is not in the motors, but in the fact that the former rating is at a speed of 600 revolutions per minute, and the latter at 1000 revolutions. Much better give the standard rating of 40.0 and avoid confusing the reader with the additional figures.

Radiators are another source of confusion. In the tables these are divided into three classes, according to their construction: verticle tube, cellular and honeycomb. The vertical tube designation is self-explanatory, with the addition that the component tubes are provided with radiating fins, or pass through closely-spaced metal sheets which answer the same purpose. Cellular radiators are those made up of flat, zigzag tubes, without radiating fins, and the honeycomb type is that originated by the Mercedes, in which the tubes are horizontal and serve for the passage of the air, while the water passes through the interstices between the tubes.

Table Signs and Abbreviations—Pumps, in all cases appearing in the tables, are either of the centrifugal or the gear types, both too well known to need description. A remarkably large number of cars, however, dispense with the pump, circulation being on the thermo-syphon principle, effected simply by the different degrees of heat of the two bodies of water, one in the cylinder jackets and the other in the radiator.

So uniform is the use of high-tension ignition by magneto that it has become superfluous merely to state its presence; and to give the most possible information, the magnetos have been designated by the names of their makers, whenever possible.

The lubrication of the motor cylinders and bearings is another field for standardization. The system of lubrication by a continuous circulation of oil, used over and over, is designated in the tables by the word "Pump." The system in which each cylinder or bearing is fed a definite quantity by an individual pump is indicated by the abbreviation "mech," accompanied by a figure showing the number of such feeds. Splash lubrication is that in which the lubricant is simply injected into the crankcase at stated times.

Clutches are divided into cone, disk, plate, and expanding or contracting band types. Change-gears are either selective, progressive, planetary or friction, all familiar terms, for which the abbreviations will be self-explanatory. The aim throughout the tables has been to avoid confusion by classifying the designs for each part into the smallest possible number of definite types, rather than to attempt to describe each part individually. With each type indicated by a given and uniform sign, reference to the tables is made easy, and yields at once a definite idea of the construction of the car in question. A glance down the columns of the table will also give an idea of present structural tendencies.

AUTOMOBILE WEEK AT ATLANTA

Leader of the rejuvenated South, Atlanta this week welcomes the industry which is expected to play no unimportant part in its development. Atlanta recognizes the importance of transportation, for the railroads first brought her prosperity; and she sees that the farm lands on which her prosperity depends will best be served by the more modern agent of transportation, the automobile.

In the modern scheme of development the railroad seems to have exhausted its possibilities. It has created great distributing centers—Atlanta stands as an example; but its scope is limited. It cannot reach every hamlet and farmhouse. The electric interurban lines come nearer to the individual producer, but still not quite close enough. Here lies the field of the automobile.

Each farmhouse can have its road linking it with the railroad station, and its automobile to use that road; and the combination of a good road and a good automobile gives the most economical form of short-haul transportation known. With good roads, every farmhouse is on the railroad.

This form of transportation is the South's keenest need, and its lack the greatest hindrance to further development. The steel rails and the locomotive have done their allotted part; the macadam road and the automobile must end the work.

Atlanta's public-spirited citizens saw this want and with characteristic energy set about supplying it. They found it necessary to work in two directions: for the country-folk had not realized that they needed automobiles, and the automobile makers had not realized that they needed the country-folk. These two bodies had to be brought together and made to see their mutual dependence.

Here Atlanta spirit came into play. Most cities would have been content with a single show or tour; not Atlanta. The program made out by her enterprising citizens included a show—a National show at that; not one but half a dozen tours, and a race meet on the fastest track in the country. Truly no small undertaking!

How the National show was secured, Clark Howell, the editor of the Atlanta *Constitution*, has related elsewhere. Ninety-nine men out of a hundred would have given up the attempt in despair, but the Atlanta delegation persisted—and won. They obtained the greatest honor that could be given any city by the united automobile manufacturers, the first exhibition of the new models: that honor which formerly had been reserved for the nation's metropolis. It was a fitting recognition of their enterprise.

Meanwhile another group of citizens were busied with the race-track. Here, too, was displayed persistence and faith of the kind which makes for success. First the necessary capital had to be raised. This did not prove as difficult as might have been expected, in view of the amount called for. But the committee found that contractors were reluctant to undertake the construction within the specified time. Persistence won another victory when a reliable firm was found to assume the contract, and when that firm fulfilled its obligation with time to spare. The track, with new records already established on its surface, awaits its opening meet.

So much for the spectacular side. The show was assured, with its splendid decorations, its polished chassis and beautifully finished cars, appealing to the esthetic sense. The races would bring world-famous drivers and speedy machines to rouse the sporting instinct. There remained the familiar, intimate side, the proximity of the dust-stained cars and their goggled drivers, traveling well-known roads and stopping at well-known inns, to wake the personal interest.

For this purpose the tours were instituted. From every point of the compass automobiles were to rendezvous at Atlanta, demonstrating at once their ability and usefulness and the failings of the local roads. Augusta, Savannah, Albany, Fitz-Gerald, Dublin, and Birmingham all send their quotas, and from New York the greatest tour of all takes its way southward. Each will pass through virgin country and will awake many thousands of country dwellers to the advantages of good roads and the automobile.

No labor could have been more unselfish, or wider reaching in its influence for good, than that of Atlanta's citizens; and, like most unselfish efforts, it will redound in no small degree to their own benefit.

Future years, we hope, will find Atlanta the center of hundreds of miles of plantation and farm land, broad hills and valleys snow-flecked with cotton and golden with corn; and each plantation and farm will be linked to its town and its railroad with bands of white macadam. Friends will be neighbors, though ten counties distant, and all will be united in fellowship and prosperity.

GOOD ROADS ACTIVITY AT FEVER HEAT IN THE SOUTH

THE good roads movement in the South is both an old and a new proposition. The desire for good roads has long been felt, and movements looking to their accomplishment have been often started. It is the method that has obtained that deserves the title of "something new."

This method was first adopted by the Atlanta *Journal*, and came in the shape of offers of cash prizes for the best road in various counties in the South. It was this offer, or rather this series of offers, that set nearly every section of the South at work, laboring for the better keep of the highways and the construction of perfect roads.

The *Journal* tour from New York to Atlanta started the real activity in this direction, and credit is due Major John S. Cohen, managing editor of this paper, for the energy that has made the movement a success. When he decided upon his plan of action, there was no time lost. He went out on the roads personally and inspected them. His title of major was well earned by active service during the Spanish-American war, and while not a man of strong physique, he has endured much hardship in the field. He was called upon to muster his courage and strength when he started on the first "scout tour."

This tour was for the purpose of locating the best possible route from Atlanta to New York. To make the trip did not mean a joy ride by any means. There were creeks and rivers to ford, bad bridges to cross, rough roads to travel, and many hardships to endure. There was one bright spot to these inconveniences, however, one saving grace for the bad things, and that was the universal courtesy, liberality, and enthusiasm of the people along the routes traveled. From the hour that the first car left Atlanta to the hour that its journey was ended in New York, the trip was one continuous ovation from every city, town, and hamlet visited. But while this is true, there was work to do, and real work. Observations had to be taken, maps had to be made, bridges tested, mountains climbed, swollen streams crossed, and a hundred and one inconveniences overcome every day. It was here that the experience and energy of Major Cohen was seen at its best.

The news of the movement and the new plan that was being put into operation spread into the most remote places, far from railroads and telegraph lines. As the car went speeding down a country road one afternoon in North Carolina it passed near a small farmhouse. The owner was seated on his porch reading when he heard a blast from the horn of the machine. He sprang to his feet and waving a paper high above his head exclaimed: "Three cheers for the *Journal* and good roads." He then gave the cheers he had just called for.

After the initial trip from Atlanta to New York, the return journey was made. But the pathfinders did not return as they had come. Instead they made their way back by a different route, and went through many hardships for the second time.

Again the generous entertainment and hearty greetings given by the citizens through whose territory the car passed made up for all the sacrifices. It had been decided before the first trip was made to give prizes to the counties having the best roads by a certain date. After this had been determined upon it became necessary to decide upon the route along which the improvements were to be made. That was really the hardest part of the task. Physical discomforts were as nothing compared to the task of disappointing hundreds of kind friends who were anxious to have their municipalities on the road. But at last the work was finished and the line selected without regard to personal feelings. By doing this the best possible results were obtained.

Then began the work of citizens, boards of trade, county officials, city governments and individuals. Roads that a few days before had been almost impassable were graded, cherted, and rolled as quickly as possible, and then more permanent improvements were begun. Bridges were constructed, drains were built, and yet the work continued. This, however, was not confined to the Atlanta-to-New York highway. Sections not on this route were not to be outdone by their neighbors, and they, too, got busy.

Movements to improve roads farther South were soon active and in a short time were general. The efforts first began in Georgia, extended to Mississippi and Louisiana. Soon the movement had gained such widespread popularity that the people in many counties decided to vote for bonds for the improvement of their roads. Men who had on previous occasions opposed the issuance of bonds for any purpose caught the good roads fever and worked in their behalf. A recent meeting of the Southern Appalachian Good Roads Congress was addressed by G. Grosvener Dawe, managing director of the Southern Commercial Congress. In his address Mr. Dawe gave some exceedingly interesting figures. He said:

"The form of good roads enthusiasm, which expresses itself in bond issues, is unmistakable. The total bond issues voted on or discussed prior to voting and still remaining undefeated, from March to September inclusive is $17,956,000. The voting of bonds shows that the public mind now recognizes the permanency of a good road, and, therefore, posterity's interest in it. The votes by States give interesting light on the whole matter. Bond issues voted, or to be voted on, by Southern States, March to September, inclusive, 1909, follow:

Texas	$5,000,000
Tennessee	3,022,000
Georgia	2,110,000
Oklahoma	1,750,000
North Carolina	1,640,000
Florida	1,600,000
Virginia	1,196,000
Alabama	850,000
Mississippi	310,000
Louisiana	298,000
West Virginia	180,000
Arkansas	....
Kentucky	....
Maryland	....
South Carolina	....
	$17,956,000

"The tide of bond-voting was strong all through the spring and early summer, ebbed during August, and has swung on strongly again during September. Bond issues voted or discussed in Southern States were:

	States	Amount
March	5	$1,615,000
April	7	3,690,000
May	9	3,319,000
June	7	2,063,000
July	7	2,674,000
August	4	1,340,000
September	8	3,255,000
Total		$17,956,000

"The State of Georgia may be said to be the livest 'old' State in the South. It stands third on bond votes, having pledged itself $2,110,000 since March. But this does not even touch the edge of the activity. There is to be more money spent in the next year by counties not voting for bonds than the $2,000,000 mentioned above. Does this sound like determination? Stewart County, 600 miles; Pulaski, 300; McDuffie, 200; Crisp, 150; Ben Hill, 100; Dooly, 100. Thirty-six counties in Georgia are going at the road problem and with vigor. The explanations are many —newspaper agitation, the State geologists' work, automobile ownership, and the plain horse-sense of the farmer. They can all be summed up in the old adage, 'in union there is strength.' These elements in any State, when they once pull together, will move the State. 'Glorious old Georgia' is completing more than 10 miles of good roads a day. Over 4,500 convicts are at work in 105 counties of the 149."

So the movement started by John S. Cohen and the Atlanta *Journal* has become almost universal in the South, and is spreading every day.

E. M. Durant, Asa G. Candler, Jr., "The Men Who Built the Track"

Robertson in Simplex Negotiating the Last Turn

HOW ATLANTA'S GREAT SPEEDWAY WAS BUILT

By ASA G. CANDLER, Jr., President of the Atlanta Automobile Association

THE building of the Atlanta Speedway and the organization of the Atlanta Automobile Association was not in any sense the outcome of a long-contemplated plan. Instead it was all thought out in a few minutes' time, and once the start was made, not a moment was lost in completing the work.

One afternoon Edward M. Durant, of Atlanta, and myself were near Hapeville, a small town adjacent to Atlanta. We had made the trip out on business far remote from that of building an automobile track. As we passed a large tract of land the identical idea seemed to occur to both of us at the same time. The idea was spontaneous, one might say, and the very instant we began discussing the question it was settled in our minds that we would start the work at once.

The land we had seen was not all in one parcel, but several scattered pieces, and in order to secure what was needed we had to make a number of trades. This was done, and then work was started on the plant.

In the meantime the Atlanta Automobile Association was organized, and the land taken over by that organization. Officers were selected by the stockholders, and they were kind enough to make me president. Mr. Durant was elected secretary, and right here let me say that he has been a most valuable man in every detail of the great undertaking.

After the association was organized the task of getting the grounds arranged and having the course laid out was placed in the hands of Mr. Durant and myself. We did not want to lose any time in having the work completed and set a time for it to be finished. We decided to have the first meet on November 9, and continue up to and including the 13th of that month. We consulted with a number of contractors and they declined to undertake the job, for we were not ready to begin until July. The idea had occurred to us in June, and after getting the needed land we had no time to spare.

Many experts looked over the situation and declared it was impossible to complete the task in the time we had to give them. They would figure a while, and then with a shake of the head tell us it was not in the power of man to accomplish the undertaking. Just as it looked as if we would have to take the contract over and do the work personally, we found a firm that was willing to take a chance. It did not take us long to come to terms, and work began almost the day the contract was signed.

We got little encouragement from any one save our stockholders when it came to discussing the time for the onening. Nearly every one declared we had undertaken too big a job for the number of days we had in which to work. We were determined, however, not to break our promise, and soon had a night force working. In order to do this a special system of lights was put in. This was done, and there was no stop except when the weather became so bad there was no chance to go ahead. The men who took our contract were experts. They had the facilities with which to carry out their part of the agreement, and did so.

Atlanta Trophy: Height, Six Feet; Value, $10,000

The plan was not one for the purpose simply of making money. It was intended to advertise Atlanta, to show to the world that the claims made for the city are not idle ones. We wanted the best plant in the country, and I think we have it. But we have just begun. The grounds are to be beautified in every way possible, and we will not stop there either.

The recent try-outs given the course by some of the greatest drivers of automobiles in the world have served to show how near perfection is the course. There was not a complaint, not a suggestion to come from any of the men who drove over the course on Saturday, October 23, but there was praise from all of them.

The Atlanta Automobile Association is composed of leading business and professional men of Atlanta. The association is going to foster automobile racing on a high plane. Everything will be done to advance the sport and to protect it. There is to be no shamming. There is not a dollar of stock in the association owned by manufacturers of automobiles or of kindred enterprises. No make of machine will ever be favored by the association to the injury or inconvenience of another. The association is free from obligations, and its only object is to give the best possible entertainment and to establish itself in the world of sports as one of the great national organizations.

ATLANTA AS THE AUTOMOBILE CENTER OF THE SOUTH

ATLANTA GA., Nov. 3—If a man should sit down with an atlas, a pair of dividers, a railway guide, and a determination to locate the exact center of the South he would discover Atlanta. By the "South" is meant that portion of the United States on the torrid side of the Mason and Dixie line and east of the Mississippi River—that portion which includes Virginia, North and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Tennessee, and maybe Kentucky (though the claimed of that last-named State to a place in the South is contested now and then owing to the inadvertence of Kentucky in not seceding, back in the terrible '60's).

It is doubtless true that the Georgia capital, the "Gateway to the South," is not the exact geographical center of the Southern States. That honor goes doubtless to some less conspicuous city—Ty-Ty or Rome, Ga., maybe. But measured in terms of railroad miles Atlanta is just exactly that place. It has the honor of being nearer to every city in the South than any other one place. To cover the Southern territory from any one central point you must locate Atlanta.

This fact of central railroad location made Atlanta.

The Georgia capital is not blessed with any peculiar natural advantages. It hasn't the river that has made Memphis and New Orleans, or the ocean that keeps Savannah and Charleston on the map; it has no coal or iron like Birmingham; no rich farming country surrounding it like Nashville; it isn't a winter resort like Augusta, or a summer-and-winter resort like Asheville. It just happens to be "near the middle" in its location.

The Union Railway Station at Atlanta

Of course, it is by no means deviod of natural advantages, not least of its blessings being a wonderful year-round climate, but it would never be the big, bustling town that it is for any reason except its railroads and its location. This location has made Atlanta a city of Southern headquarters. Insurance companies, manufacturers, wholesalers, retailers, and now, at last, automobile manufacturers have chosen the city for their main office in Dixie. And these Southern headquarters have made the city rich and famous.

They have also made Atlanta a city of office buildings. Atlanta has more skyscrapers than any other Southern city, and the building of them has only just begun. It also has wonderful other buildings of various sorts, and an amazing supply of warehouses, including the new L. & N., which, when built, was the largest concrete structure of its kind in the world.

Atlanta is not alone famous for its office buildings and its office population. Fulton County, in which Atlanta is located, produced $15,000,000 worth of manufactured goods in 1900, and double that amount in 1905. Now the yearly amount is $40,000,000, and constantly growing.

Of course, the fact that Atlanta is the capital and largest city of a State that produces $100,000,000 worth of cotton a year has something to do with its growth, as has also the fact that it is practically the center of a group of States that grow $300,000,000 worth of cotton a year and turn out cotton goods worth $150,000,000.

All of which being true, is it any wonder that Atlanta has become the center of the Southern automobile business? Probably not, but even with all these facts staring in the face of any man who looked for them it was only a couple of years ago that Atlanta began to take its proper place in the automobile world.

From the time that the automobile makers broke gently into the South until a couple of years ago, all business was handled directly from the factories, through representatives in the various Southern cities. But the makers found this unsatisfactory as a method, because they were far from the actual scene of the selling battle and because they did not know Southern conditions. As long as the South was consuming few automobiles any selling method was good enough. But when the South woke up to the cars, the makers had to wake up to the South.

The honor of discovering Atlanta belongs to the Maxwell-Briscoe Company. This company had in J. M. Austin a live Atlanta agent, but it had been contented to do business in one small store, with the front part of the building fixed up crudely as an office and the back part as a garage. Then one day the announcement was made that the Maxwell-Briscoe Southern Company had been formed and that it would have a new place of business. At that point Atlanta began to exist as a Southern automobile headquarters.

The White company was only part of a lap behind. Before the Maxwell-Briscoe company was well in its new place the Cleveland makers shipped E. W. Gans to Atlanta, stationed him at the Piedmont Hotel, and closed a contract for a Southern headquarters. The company secured a handsome fireproof, concrete building, moved in, and immediately set the South ablaze. The success of the Southern branch was instantaneous and phenomenal. It sold all the cars that were assigned to it, and clamored for more. These were not then forthcoming, which caused disappointment.

What the White company was doing with high-priced cars the Maxwell-Briscoe company was doing with the lesser-priced machines. Its cars sold faster than the branch could get them, and a year in the South served to intrench the company most firmly. And, incidentally, it served to intrench Atlanta and the South most solidly in the heart and the pocketbook of the company, and only a year after the Maxwell-Briscoe Southern opened in Atlanta it was forced to vacate its original place and move into a new one, over twice as large. And soon after that the White company spread out to occupy more of the building it was in, and the business multiplied in proportion.

The third Southern branch opened was by the Buick company. This concern, though a bit behind the other two in discovering Atlanta went into it strong when it did make the start. The company secured a fine two-story warehouse and a garage on Edgewood Avenue and spacious showrooms on North Pryor Street, which were fixed up in a befitting style.

The other Southern branches are of more recent vintage—most of them, in fact, were opened this year. The Overland Southern Company, for example, has just been organized and did not get possession of its place of business, the old Peachtree Auditorium Garage, until October 15. This company has a broad territory and one of the largest garages in the South. The Olds-Oakland Company is another Southern branch of the vintage of

The Mansion of the Governor of Georgia

1909. Within the month it moved into its Peachtree Street showrooms, and it has not as yet secured its permanent garage, though the building is in process of construction.

The Haynes company practically established a Southern branch when it gave the agency for a very large part of the South to the Corker Auto Company. This concern, like the Olds-Oakland company, has closed for a big garage, and is soon to move into Peachtreet Street showrooms.

Another Southern branch secured by Atlanta within the year was that of the Lambert car, which is now handled for all the South by the Southern Auto & Equipment Company.

This represents the Southern branches now established in Atlanta. More are coming. Several companies, some of them of real prominence, are now looking over the local field, and another year will see them established in Atlanta.

Atlanta promises also to lead the way in the manufacture of cars. The White Star car, manufactured by the Atlanta Buggy Company, 80 Means street, is the first Atlanta car. This company began the manufacture of cars last year. The first product of the White Star factory was a high-wheeler. After a year of manufacturing the buggy type the company shifted to the conventional model, and is now getting out a highly creditable car. Another company has been announced which hopes to begin the actual making of cars by next spring.

As the tire center of the South, Atlanta has always been "it." Even before the car makers had discovered the strategic importance of the city, the tiremakers were "on." Early in the industry they had begun to establish Southern branches, and now practically all of the tire makers of importance have Southern headquarters in Atlanta.

There are no bounds to the possibilities of Atlanta as the center of the Southern trade. The enterprise in securing the Southern show helped to make certain Atlanta's position in the automobile world. The building of the big, expensive two-mile track will have its influence. The enterprise of Atlanta in getting up the runs from New York, from Birmingham, and from the Georgia cities will play its little part in focusing the eyes of the automobile world on Atlanta.

In Ansley Park—A Fine Residential Section

While the other Southern cities have been content to take such agencies as came to them, Atlanta has gone out for the big agencies and the Southern branches and has landed them. It has grown with bounds in the automobile world and there is no limit in sight. Atlanta is now the Southern headquarters of the automobile business, and from all appearances ever will be.

TWO THOUSAND PER CENT. INCREASE

Macon, Ga., Nov. 1—One motor car in 1902, five within the ensuing twelve months and 279 in 1909—these figures tell the growth of the motor car business in Macon. For as the sale of machines increased, agencies sprang up and garages came into existence, and the car dealers came to be regarded as one of the city's established business men. Macon eventually will be one of the motor car headquarters of the State. This is attributable to the fact that it is located in almost the geographical center of Georgia, with practically every principal railroad in this part of the country operating freight and passenger service in and out, and all prominent roadways—much the same as "all roads lead to Rome"—leading to it.

There are now six garages. Two of them compare with any in the South, both in size and in point of equipment. These garages are owned by the following: H. K. Burns, the Taxicab Company, Henry J. Lamar, Jr., G. Fred Ellis, J. W. Shinholser, Christian Huhn and John S. Schofield. The garages rent cars, repair them, sell supplies, and are the headquarters for as many agencies. Owing to the rapidly increasing number of cars in the city, each of the garages does a large business. The following agencies are located here:

Automobile and Machinery Co	Oldsmobile and Oakland
G. Fred Ellis	Ford
Maxwell-Briscoe Co.	Maxwell
J. S. Schofield	White
C. Huhn	Jackson and Reo
J. W. Shinholser	Chalmers-Detroit
E. C. Momand	Studebaker
Willingham & Wheeler	Velie
S. S. Parmelee & Co	Buick
Henry Jones	Overland
Southern Auto and Supply Co	Hupmobile

The good roads movement in this State was formally launched in Macon and received its first important impetus here, principally through the efforts of the late Ben. L. Jones. Bibb County roads are considered the best in Georgia, without exception, and as Macon is the county seat, the motorists here have many advantages for pleasant driving. There are numerous straightaway stretches beginning almost within the city limits, chief among them being the Columbus, Houston, Seven Bridges, Outing Club and North Highland roads. The county keeps its entire force of convicts constantly employed on these roadways, improving, building up and creating, and also employs nearly fifty State convicts, all under the same management, for the same purpose. Credit for much of the good roads work in recent years is due to Superintendent E. A. Wimbush. The city of Macon offers little or no restrictions for motorists, and the county puts no obstacle in the way of motorists. A municipal regulation against over eight miles an hour is not enforced.

Conservative estimates place the valuation of the motor cars and garages in Macon at nearly $800,000. The majority of the cars here are high-priced, while in one garage alone, that of G. Fred Ellis, which is just nearing completion, more than $100,000 is invested. This garage has a marble finish street frontage of 100 feet and a quarter of an acre store room.

Every agent in Macon is optimistic over the outlook for business. They state that a prosperous cotton season will insure the sale of scores of machines in this particular territory, if not in the city proper, and all of them are ordering extra cars in anticipation of this large trade.

ERA OF MOTOR CAR IN ALABAMA

Birmingham, Ala., Oct. 30—The era of the motor car has settled over the entire State of Alabama with irresistible force. The motor car in this State has become a commercial necessity. The boom of the car has been marvelous and unprecedented. That the popularity of the motor is to be permanent is illustrated in the fact that many of the local agencies have booked heavier than ever before for a future season's output.

Along with the motor car fever has come a persistent cry for good roads and more good roads. The good road movement is well launched in Alabama. North Alabama has taken firm hold. South Alabama is not far behind. Senator John H. Bankhead is canvassing the State at the present time in the interest of better roads. Enterprising clubs are making and planning to make long-distance journeys. The countryman is stirred up and will render valuable assistance.

The city of Birmingham up to the present time this year has licensed 543 cars. There are in Birmingham and its suburbs 782 machines. Among this number, practically every make is represented. There are fifteen motor car agencies handling practically every make, and Birmingham is preparing to manufacture cars. The Birmingham Automobile Manufacturing Company, with a capital stock of $100,000, and with E. F. Euslen, president of the Jefferson County Savings Bank, as president, has been organized. The new company will manufacture a six-cylinder machine. Here follows a list of the agencies and the machines handled by them in Birmingham proper:

Citizens' Automobile Co.—Marion, Overland and Ford.
C. C. Nixon & Co.—Cadillac, Pierce-Arrow and Pope-Hartford.
Southern Garage Co.—Packard and Franklin.
Highland Garage Co.—Marmon.
Drennen & Co.—Buick, Stevens-Duryea and Peerless.
Birmingham Garage Co.—Studebaker and Oldsmobile.
Loveman, Joseph & Loeb—Chalmers-Detroit, Thomas, Hudson and Stearns.
Cooper Garage Co.—Jackson and Hupmobile.
Maxwell Agency—Maxwell.
N. O. Tyler Co.—Reo and Kissel.
Walter Moore & Co.—Stanley steamer.
Magic City Garage Co.—Mora and Mitchell.
White Garage—White steamer and White gasoline.
Lambert Agency—Lambert.
T. S. Smith & Sons—Premier, American and Moline.

MANY AGENCIES IN THE FIELD IN MEMPHIS

Memphis, Tenn., Nov. 1—From a city practically unknown on the motor car map of the United States to what promises to be the mecca of the southern motor car world, is the rise of Memphis since 1901. It was in this year that the Bluff City was formally introduced to the horseless mode of travel, in the shape of a steam locomobile, and has gradually conceived the idea that the motor car is as much of a necessity as a luxury.

In 1901 Jerome P. Parker & Co., at that time exclusive dealers in bicycles, purchased six high-seated steam locomobile runabouts and after tireless efforts succeeded in disposing of the last one in 1903.

In 1903 other agencies were secured, the car business began to strike its roots and has gradually grown until there are now seventeen motor car dealers in Memphis representing about thirty factories. The present list is as follows:

McDonald Automobile Co.—Studebaker-Garford, Studebaker-Flanders and E-M-F.
Memphis Automobile Co.—Packard, Chalmers-Detroit, Baker electric, Babcock electric.
Jerome P. Parker Co.—Stoddard-Dayton, Overland.
Frank C. Blomberg Co.—White.
Cullen-Butler Auto Co.—Premier, Reo, Grabowsky trucks.
Fal Motor Car Co.—Factory branch.
H. A. White & Co.—Pierce-Arrow, Cadillac.
Bruce-Cubbins Co.—Locomobile, Stevens-Duryea.
Lily Carriage Co.—Peerless, Waverly electric.
Buick Motor Car Co.—Factory branch.
Rodgers-Oliver Co.—Hupmobile.
Southern Auto Co.—Maxwell.
Knox & Jevell—De Tamble.
W. S. Bruce & Co.—Ford.
Williamson & Hobson—Trucks.
Garages—McDonald Automobile Co., Jerome B. Parker Co., Cullen-Butler Auto Co., Memphis Automobile Co., W. S. Bruce & Co., Rodgers-Oliver Co.

The activity of the city in providing the means of travel has been ably seconded by the county authorities until to-day Shelby county, of which Memphis is the county seat, boasts of more than twice the extent of improved highways than any other county in the State. From an appropriation of $40,000 twelve years ago the annual appropriation for the building and maintenance of free gravel turnpikes has been increased until for the past five years it has aggregated $100,000 and as a result over 600 miles of free gravel turnpikes entice the traveler.

North Pryor Street, Which Is Atlanta's Automobile Row

MANY FINE PIKES AROUND NASHVILLE

Nashville, Tenn., Nov. 1—Nashville can make the boast that one of the first successful motor vehicles in America was made in its entirety in this city by a Nashville boy, G. Preston Dorris, who since has forged to the front and is now at the head of a successful motor car factory in St. Louis. Nashville also can boast that it has kept up with the procession in the motor car world, and prospects are not brighter anywhere in the world than they are right here for a still larger use of the car both for pleasure and for business. No other city in the country, and especially none other in the South, can offer the same advantages to the owner of a car as Nashville.

Rock City is the nickname that long has been given to Nashville, and this name is an explanation of the good roads. Nashville is built on one great solid rock. It is impossible to dig over three or four feet in the ground, except right in the river bottom section, without striking solid rock. A rock strata underlies most of middle Tennessee, but at a greater depth than right here at Nashville. But it is possible anywhere to get all the rock wanted for road-building without having to haul it a great distance. This has made road-building comparatively cheap and good solid pikes will be found for many miles around Nashville in every direction.

Duncan Dorris, next to his brother Preston and Mr. Chester, deserves credit for building up the motor car industry in Nash-

In Front of Georgia's State Capitol at Atlanta ville. Mr. Dorris opened his shop for motor repair work next to his bicycle shop in 1903. In two years his business had grown to such an extent that he in 1905 erected a big garage of his own just on the edge of the business portion of the city. Although the place he opened is 50 by 150 feet and at that time seemed to be far ahead of all needs, he has already become very badly crowded. This was the first exclusive garage in Nashville. The list has now grown to the following:

Chester Motor Car Co., agents for Studebaker and Mitchell, general public garage and repair work.
Nashville Motor Car Co.—Dorris, Buick and Stanley, general repair work and public garage.
Rock City Auto Co.—Reo, general repair work, garage, supplies.
Tennessee Automobile Co.—Studebaker and E-M-F, repair shop, garage.
Bell Antomobile Co.—Repair shop and garage.
Southern States Automobile Co.—Stevens-Duryea.
Howard-Cregor Co.—Chalmers-Detroit and Hudson.
E. E. Houk—White and Hupmobile.
Nashville Auto Livery and Repair Co.—General repair work.
J. S. Roller—Ford and supplies.
Nashville Taxicab Co.—Operating a line of cabs for public hire. It has its own garage and does its own repair work.

GOOD ROADS IN MECKLENBURG COUNTY

Charlotte, N. C., Nov. 1—Mecklenburg County is the premier good roads county in the entire South, and Charlotte, the county seat, is the leading motor car center of the two Carolinas. For a radius of fifty miles, a distance which laps over into South Carolina for forty miles, most all the cars sold are sold through contracts held by Charlotte agents. The city has a population of 45,000.

In the city there are 132 machines in daily use, and this number is being added to every few days. The county is the richest in the State and the spirit among the citizens is one of progressiveness and thrift. It is styled the Queen City of the South and the City of Electric Energy. Within a radius of 100 miles are 425 cotton mills, operating 5,511,543 spindles, 120,000 looms, and representing $150,000,000 in capital. There are twenty-six miles of electric railway, operating twenty-three cars. Seven banks have a total of $9,976,000 assets. The four building and loan associations have an authorized capital of $13,000,000. The city has fifty-three miles of paved and macadam streets.

Hand in hand with this wonderful growth is the motor car industry, which was introduced by Osmond L. Barringer. He bought a Locomobile runabout in 1899. In 1903 Mr. Barringer opened a salesroom and launched the business which was the first in this section and perhaps the first in the State. In a year he had placed six machines, and after that time the people began to buy more rapidly. The market has been growing ever since and to-day there are six concerns in the city selling motor-driven vehicles.

Of the 132 machines in the city twenty-two are used by physicians. This is about 60 per cent. of the physicians in the city.

In July last the local owners organized the Charlotte Automobile Association which now has a membership of eighty-five, or about 64 per cent. of all the owners in the city.

Through this section will be found the best public highways in the South. Mecklenburg County alone has 210 miles of macadam and more under construction. There are 46,850 miles of public roads in the State of North Carolina, about 800 of which are macadamized. The work of road building was begun in Mecklenburg County in 1884.

SCRAPPERS FOR ROADS IN WINSTON-SALEM

Winston-Salem, N. C., Nov. 1—Here we have a hundred cars, and hardly a week passes that the number is not added to. Here we have three garages, each doing a thriving business. Here we have a machinery factory preparing, with material ordered, for the manufacture of motor delivery wagons. And here we have the first car ever brought into North Carolina.

The oldest garage in the city is that of the Winston Automobile Company. This company, organized 2½ years ago, has placed many Maxwell machines in use, and the sale continues.

Next in point of age is The Motor Company, whose garage is situated on Main Street, next to the Zinzendorf Hotel, which was official headquarters for the night control of October 29 for the good roads tourists over the national highway from New York to Atlanta. This company has sold scores of Buicks and Studebakers. Though The Motor Company was organized as late as May 1, 1909, the business has grown to such an extent that in January the floor space of the garage will be doubled, making the house extend the entire length of a block.

The Southern Motor Car Company, organized May 8, 1909, is the State agency for the Cadillac machine.

HEALTHY CONDITIONS EXIST IN RICHMOND

Richmond, Va., Nov. 1—On August 1, 1905, William W. Archer registered the first motor car that had ever been entered on a license book in the State. The entry was made at Richmond police headquarters. As the manner of keeping the registry at that time had not been subjected to a test, the address of Archer does not appear with the issuance of the certificate. The machine which this motorist used was a Knox three-wheel gasoline car, seating four people.

Richmond and Atlanta, perhaps, lead the South in the number of motor cars which pass through the city limits. This has been greatly augmented by the work of the good roads enthusiasts going out from Richmond, Washington and Atlanta to all parts of the States between Virginia and Georgia. From the books of the State Auditor it may be seen tbat there have been issued already—to October 10—3,321 certificates for the right to use motor cars in the State of Virginia. As the State license fee is only a paltry sum of $2, one-fourth of which goes to the clerk who issues the certificate, the State already is looking toward a complete revision of the laws governing machines in Virginia, which will more than likely be changed almost in the entirely at the next session of the Legislature, which convenes in January.

The comparative figures in the State Auditor's office show that the year 1909 has given an increase in registration over 1908 of 1,400 machines or nearly as many as half the total registration since the year 1905. It is the beginning of the motor car age in the State and the fever has taken root in every State in the Southeast, to say the least of the Southern situation. The increase of 1908 over 1907 was 700 registrations, or half of that of the present year. The State Auditor estimates that one-half are in Virginia, or something like 1,700 machines.

From the books of the clerk of the chief of police, where city entries are registered without fee, there is shown a total since August 1, 1905, of 3,309 cars. These, also, are estimated to be about one-half owned by Richmond people and the others registered by visitors. The difference in the number registered in the city and State being only 312 machines, it would indicate that the road to Richmond is a Mecca or else that registration has been poorly carried on.

Taking the city registration, it would show that on January 1 of this year there were registered 2,110 motor cars. Going back a year the number was only 758. This is an increase of that year of 441, which, compared with the total to date of 3,309 cars registered, shows the increase to be remarkable.

To-day seven big garages are doing business in Richmond. They represent eight types of manufacture and every known style of these manufacturers. The agents and the machines are as follows:

Virginia Automobile Co.—Ford.
Richmond Supply Co.—Reo.
Foster Motor Car Co.—Franklin and Buick.
Ross & Schuluter—Overland.
B. A. Blenner—White.
Central Garage—Maxwell.
Gordon Motor Co.—Chalmers-Detroit.

In addition to these there are three agencies in Richmond for as many motor cycle companies.

Never in the history of the State has the good roads question assumed such proportions, and there can be no question of the fact that, though the poor farmer is used in stump speeches he is, or will be, the power behind the throne in the motor car.

Good Roads Tourists on Southern Tour Leaving Winchester, Va., on the Road to Staunton

LIKE ROLLING SNOWBALL, ATLANTA TOUR GROWS

NINE STATES have been met and conquered by the sturdy band of automobiles bearing the "Good Roads" banner from New York to Atlanta, and in each successive State the enthusiasm for the cause seems to grow. Each day's trip scored a new triumph. The tourists, in passing through communities where automobiles are seldom seen, spread the gospel of macadam, and in return received their own object lesson in the difference between what roads should be and what they often are.

The worse the roads, it seemed, the more hearty the greeting and the more intense the interest shown through the countryside so afflicted. Villages and cities poured out their people to cheer the tourists. Solitary crossroads, far from farmhouses or other signs of habitation, were marked by groups of farmers with their families, who in many instances had traveled scores of miles and waited many hours to see the cars speed past.

Schools were suspended for the day, and the fences near these little homes of learning were clustered with children, each a prospective advocate of good roads. Villages which have been the most clamorous in their warfare against automobiles have experienced a complete change of heart. All along the route the talk is of good roads and the means by which they may be obtained at the earliest date. As a popular educator the tour finds its crowning success.

Third Day's Run—Gettysburg to Staunton

STAUNTON, VA., Oct. 27—Never was Southern hospitality, famous the world over, more spontaneous or delightful than that which greeted the participants in the New York *Herald*-Atlanta *Journal* tour to-day. For 180 miles the procession was like the return of a victorious army; indeed, to the tour, victory seems already assured.

Starting from Gettysburg at seven o'clock this morning, they traversed the southern section of Pennsylvania, crossed the narrow western neck of Maryland and the northeast corner of West Virginia, dropping then into historic Shenandoah Valley.

It was the longest day's run scheduled for the tour of approximately 1,100 miles. Contestants were forced to drive their cars over roads of all sorts and conditions, and yet but one competing car was penalized for failing to make the day's trip within the schedule time, while another met with an accident which damaged the automobile and probably put it out of the contest, though luckily neither of the two passengers was injured. In addition, penalties were laid upon four contestants by Referee Scarritt for violation of road rules.

Near Middletown, Va., about sixteen miles southeast of Winchester, where the noonday halt was made for luncheon, the Oldsmobile, entered and driven by Frederick Weis, of Brooklyn, crowded close to the edge of the highway in seeking to pass the Craig, a non-contesting car entered by the Ajax-Grieb Rubber Company, which carried supplies of tires. As it came abreast of the latter machine a wheel of Mr. Weis' car struck a big stone flanking a culvert at this point, causing the Oldsmobile to skid violently into collision with the Craig. One of the rear wheels snapped off, sending the car into a ditch fringing the roadway.

The Thomas car, driven by Mrs. De Giers, of New York City, had the misfortune to break a steering knuckle, and as a consequence was forced to lie up for more than three hours while a roadside blacksmith mended the break. It had almost regained its schedule for the day's run, when just outside of this city it suffered three tire punctures. Because of the additional delay the car arrived late and received a penalty of 67 points.

Fourth Day's Run—Staunton to Roanoke

ROANOKE, VA., Oct. 28—Though to-day's route, approximately 93 miles, lay through the "backwoods" districts of the Blue Ridge and formed the most truly rural course yet traversed, village

Quaker Children Enjoying the Passing of the Tourists and Having Their Pictures Taken on the Alco

streets and secluded crossroads were dense with throngs that plied a welcoming bombardment to the good roads campaigners.

Roanoke struck the climax this evening with its roaring welcome. From the clouds of dust hanging over the roadways the cars shot into the streets that had been specially sprinkled for their comfort. The brass band blared its harmonies, while its citizens invited sore throats by the intensity of their chorus.

The day's run lay through historic territory. The tomb of General Robert E. Lee, in the ivy shrouded chapel of Washington and Lee University, in Lexington, was visited by the tourists en route. They were spectators of a special battalion drill by the cadets of the Virginia Military Academy, located in the same city, the institution where "Stonewall" Jackson was a professor of mathematics when he took up arms to fight for his country. They viewed the glories of Natural Bridge, where the noon halt was made for luncheon, and sent their cars climbing along the winding roads that pierce their way through the Blue Ridge Mountains.

For fifty miles out of Staunton, the new national highway, terracing constantly to higher levels, led the way up into the mountain altitudes. The village of Fairfield had arched its main street with a great banner, which voiced the words in big letters:

"Welcome, Tourists—New York to Atlanta."

Virginians' Welcome to the Good Roads Tourists

On the ridges hemming in the roadway, flanked to the left by the towering heights of the Blue Ridge, their forested slopes gay in the colors of autumn and blanketed with a bluish haze, groups had assembled as if in so many grand stands.

All but one of the thirty-five contesting cars rolled in at the finish on schedule time and without a single penalty levied upon them as a result of the day's run.

The car which failed to arrive was the Thomas, entered by Mrs. F. De Giers, of New York City. This contestant had the misfortune yesterday to break a steering knuckle. It had been supposed that the party had given up the contest, but this evening a telegram was received from Lexington, fifty-five miles away, addressed to the official checkers, and saying:

"Don't go to bed until we are checked in. Are enjoying moonlight ride. MRS. DE GIERS."

Fifth Day's Run—Roanoke to Winston-Salem

WINSTON-SALEM, N. C., Oct. 29—Through the grazing reaches of Virginia, the tourists carried their doctrine into the great tobacco-growing belt of the Carolinas. Mountaineers, buried in their little homes, clustered in the recesses of the hills, threw aside reserve and made the parade of the good roads pilgrims a triumph. Unchecked enthusiasm rang its tumult everywhere along the line. It stamped the countryside's united support to the movement which the tour represents.

Immediately after leaving Roanoke this morning, with the sun beaming from a clear sky, the motoring pilgrims struck eight miles of mountain grades. Hedged in by the forested hills, glowing in their autumn dress, the line of cars dashed through stream after stream, as they swept about the sharp corners and chugged up the slopes.

At Maggody Creek, in Franklin County, Va., twenty-one miles from Roanoke, came the most striking evidence of that State's loyal support of the good roads campaign. Until three weeks ago this stream was bridgeless. It was forded by chance automobiles and wagons, the approaches to the dash through the water being especially tortuous and treacherous with accumulated mud. Within that period, through the efforts of F. W. Clair and H. D. Dillard, members of the County Highway Committee, a modern iron bridge more than one hundred and fifty feet in length had been hastily constructed.

Four of the competing cars failed to arrive here within the period of actual running time allotted to the various classes.

F. D. Hughes, of New York, driving a Chalmers-Detroit, wired that owing to illness he and his wife would spend the night at Martinsville, Va., where the noonday stop was made for lunch, and would try to rejoin the tourists in Charlotte, N. C., where to-morrow's run will end.

The entrants delayed in reaching this checking station of the fifth day's run, aside from Mr. Hughes, included Mr. and Mrs. F. J. De Giers, of New York City, who have had trouble for two preceding days with their Thomas car owing to the breaking of a steering knuckle on Wednesday last; the Maxwell car, entered by its makers, which is understood to have broken an axle while fording Big Chestnut Creek, with its muddy approaches, back in Virginia, and the little Franklin car, which has been driven by George H. Storck, of Jacksonville, Fla.

A telephone message brought the information that the last-named car had stripped a differential gear.

Pacemaker Sees Some Southern Joy Riders Ahead

Sixth Day's Tour—Winston-Salem to Charlotte

CHARLOTTE, N. C., Oct. 30—North Carolina believes in the adage that actions speak louder than words. To-day's route lay, in part, over macadam roads that for excellence ran a close race for supremacy with the modern highways of New Jersey and Massachusetts. Within the last few months county after county has expended tens of thousands of dollars in bettering its roads.

High Point, N. C., centre of the furniture manufacturing industry of the South, and ranking next to Grand Rapids in its output of household and office furniture, flagged the cars and served the tourists, who had breakfasted heartily in Winston-Salem only two hours before, with sandwiches and coffee.

As was figured by a mathematical expert to-night, each tourist had partaken of nine different and distinct meals before coming into contact with the commissary forces of Charlotte at the close of the day's run this evening. The menus varied from roasted 'possum and baked sweet potatoes to the national ham sandwich and its universal associate, steaming coffee.

Charlotte opened wide its arms to receive the pilgrims. Its entire downtown district had been draped with incandescent bulbs that flamed it into a monster "court of honor." There was a reception committee large enough to have cared for an army. Here the weary tourists, who have gone to bed late for a week and risen at daylight to continue the spreading of their gospel, prepared to find rest over Sunday.

Of the six cars which have practically dropped out of the contest for the tour's prizes two of the entrants have flashed word that they will continue to run until the Atlanta goal is reached.

Joseph D. Boyd, driver of the Maxwell, entered by its manufacturers, was the author of a wire from Martinsville that he would try to rejoin the column before its departure from this city on Monday morning. Back at Stoneville, near the North Carolina line, George H. Storck has the village blacksmith laboring with the fractured differential of his Franklin car, and a telegram from him affirmed that he would continue to the Atlanta checking station.

A leaking gasoline tank on the Selden, entered by Evelyn Harris, of Atlanta, caused a lively fire to-night which nearly put several of the contestants out of the running. A cigarette-smoking pedestrian, as usual, started the trouble. However, the blazing car was quickly pushed away from its neighbors. It is hoped that the Selden can be put in condition to-morrow. Everyone is rejoicing at the prospect of a day of rest.

Seventh Day's Tour—Charlotte to Greenville

GREENVILLE, S. C., Nov. 1—This city is a growing center of cotton manufacturing, in the very heart of the industrial region of the "New South." The country roads are flanked by illimitable fields of cotton, where all hands are busy—or were, till the tour came by—gathering the snowy bolls. Villages were marked by humming cotton gins, and long buildings of new red brick in which the whirring of many spindles told its story of development. Electric power, gained from waterfalls in the distant hills, is in universal use; the fields are crossed by rows of steel towers bearing the high-tension cables.

Crowds, Mostly Women, that Lined the Roadside Cheering Thomas Car at a Hilltop near Shepherdstown, Maryland

Entered by the Chamber of Commerce of Roanoke, Va.

Winston-Salem's Board of Trade Seeks Population

The ferry over the Catawba River, 11 miles out of Charlotte, was a new experience to many of the tourists. The single barge was linked to a long cable that crossed the stream, and was propelled partly by the force of the current and partly by long poles wielded by the negro crew. Each trip took two cars across, and occupied five minutes, so two hours elapsed before the forty-four had been transferred. Owing to this delay, the cars were not formally checked out for the day until the river had been crossed.

King's Mountain, where Revolutionary history was made, furnished an inspiring example of the practical results of the good roads movement. Within the last five months a stretch of macadam has been built, in many places blasted through the solid rock, with many bridges reducing grades and crossing streams.

The noon stop was at Gaffney, S. C., where the tourists lunched on tons of barbecued 'possum and young pig. Spartanburg, too, had tables set in its public square, with piles of sandwiches and gallons of steaming coffee. In the Hotel Ottaray, at Charlotte, there was a public reception, and Mayor John B. Marshall voiced the city's welcome.

Eighth Day's Tour—Greenville to Commerce

COMMERCE, GA., Nov. 2—This city welcomed the tourists this evening with a demonstration unsurpassed anywhere on the route. In the main street, a squad of 'possums peered down on the crowds from a persimmon tree walled in with bales of cotton. Confederate veterans armed with shotguns fired a volley as each car appeared, and the mill whistles were tied open for hours. At an open-air mass meeting, John N. Holder, speaker of the Georgian House of Representatives, made the official address.

To-day's run of 110 miles brought several contestants to grief, and the number of perfect scores has fallen to twenty-six.

Twelve miles out of Greenville the Jackson, driven by Jacques Futrelle, sustained a bent axle. The roadside blacksmith overcame this trouble after some delay, but near Anderson, S. C., in trying to avoid a farmer's wagon, Mr. Futrelle ditched the car. The Maxwell, which became a non-contestant several days ago, attempted to act as Good Samaritan, but broke a gearshaft in the effort. Both machines are expected to be in line for the start to-morrow.

The White Star, Atlanta's pride, twisted its crankshaft, and was towed in by Mrs. Cuneo and her Ranier. W. A. Kelly's Knox broke a throttle connection, and came in late with a penalty of 148 points. The Winston-Salem Studebaker lost a rear wheel near Lavonia, S. C., but was repaired and got in with only 27 points penalty chalked up against it.

To-morrow's charge on Atlanta begins at seven o'clock. The tourists are tired but happy, for everywhere they have seen results of their good roads gospel, and the promise of even greater advances in the months immediately to come. More than a thousand miles have been covered, and the goal is but 81 miles distant. A thousand cars are expected to form the escort into the Gate City from Decatur; but the Atlantans will have a hard time to beat the records for hospitality which have been made already along the route.

2. MAXWELL,	Dearley,	2:28:28[4]	51:1 m.p.h.
3. MAXWELL,	See,	2:30:24	50.4 m.p.h.
4. HUDSON,	Ainslee,	2:31:47[2]	50.0 m.p.h.

SIX consistent cylinders in an Alco car intelligently driven by Harry F. Grant survived most successfully in the fifth competition for the Vanderbilt cup. Survived is the correct word to use in connection with the telling of the name of the winner, for the classic event, with its usual Long Island setting, never before had a course which so severely tried the enduring qualities of the participants. Shortening the circuit by more than half that of previous years, reduced the county roads mileage but retained the entire length of completed parkway, which has a surface that exacts strenuous toll as the price of racing speed. And on Saturday last the 278.08 miles contained over twice as much as was included in the 1908 course.

Even most of the wiseacres overlooked the level-headed Grant in the reckoning, losing sight of the fact that he had Lowell's big prize as good as won when on the concluding lap the breaking of a chain robbed him of victory and caused the stellar honors to go to Robertson. Missing the Fairmount Park race because of an eleventh-hour misfortune almost as exasperating as the happening at Lowell, may have had much to do with placing the Grant-Alco combination in the possible, but not in the probable column. Robertson had added another to his long list at Philadelphia, and, though the winner of last year's Vanderbilt, the sturdy George didn't consider the inducements sufficient to bring him to the starting-line this time. Hence, the form-pickers had slight call to compare the two in predicting a winner, and Grant's work was not appreciated.

While it is true that the 1909 Vanderbilt field rated as the least brilliant in its history in the matter of known drivers, it is apparent that the caliber of the cars, remembering their stock chassis basis, excelled in all-around enduring qualities despite the meager number of finishers which overcame the punishing effects of the parkway passages. To appreciate how severe this was, one had to learn of, or, better still, be a witness of what abuse came to the cars during the practice period.

Grant sized up the situation like a general, for while some of his opponents were beating the life out of their cars, he pursued the even tenor of his way, confident that the seekers of fast lap honors would eliminate themselves before the 22 circuits had been completed. Grant's final circuit was his fastest, it being at an average of 71.9 miles an hour. For the entire race, his speed was at the rate of 62.77 miles per hour, slower than the 64.38 of Robertson in 1908 over a better course.

Strang was a "down-and-outer" in two laps, his Fiat suffering from a broken radiator. Mitchell's Simplex disappeared in the third round with a broken crankshaft. Hearne was the next to become a non-combatant, the second Fiat cracking a cylinder and breaking a connecting rod. Chevrolet overtaxed the Buick with the fastest lap of the race, cracked a cylinder, and then became an onlooker in the fifth round. And so the rivals retired, one after another, until only two finishers remained with two others up and doing.

Grant had followed his own ideas, heedless of the others, and gradually had worked his way to the leadership and the winning of a noted cup. Parker, a driver who is of a promising sort, figured as the runner-up in the remaining of the three Fiats, and, owing to a confusion among the officials, the announcement had been made that he was in the lead. Amateur Wishart, with a three-year-old Mercedes, and Elmer Knox, with the quite notable two-cycle Atlas, were navigating the circuit when Referee Vanderbilt called off the race.

Preceding this action there had been a flurry of excitement when a protest emanated from the Alco pit that its car had not been given credit for all of its laps, one being short in its score. Arthur Jervis, pioneer of cycle races galore and a logical graduate into automobiling, had not taken any chances with so-called official score-taking, and when he surprisedly became aware that the car in which he was interested ran second instead of first in the minds of timers and scorers, his aggressive objections quickly culminated in an admission that the official score was in error. Starter Wagner just had time to rush for the check-block flag and then wave it in the face of the finishing Alco. Naturally there was a demur from the Fiat camp, where the delusion had been cherished that Parker was on his winning round, but the evidence adduced left no doubt as to the right of the Alco to the place; and so the referee ruled.

As the result showed, the distinction between the Vanderbilt cars into classes 1 and 2, according to A. A. A. rules, was needless. Of the cars which belonged properly in class 2 (301 to 450 cubic inches piston displacement), none finished, although No. 7 Chalmers completed 19 laps and No. 5 Atlas was still running when the race was stopped. For this reason, there was no award in this class, the special Donor's trophy being withheld.

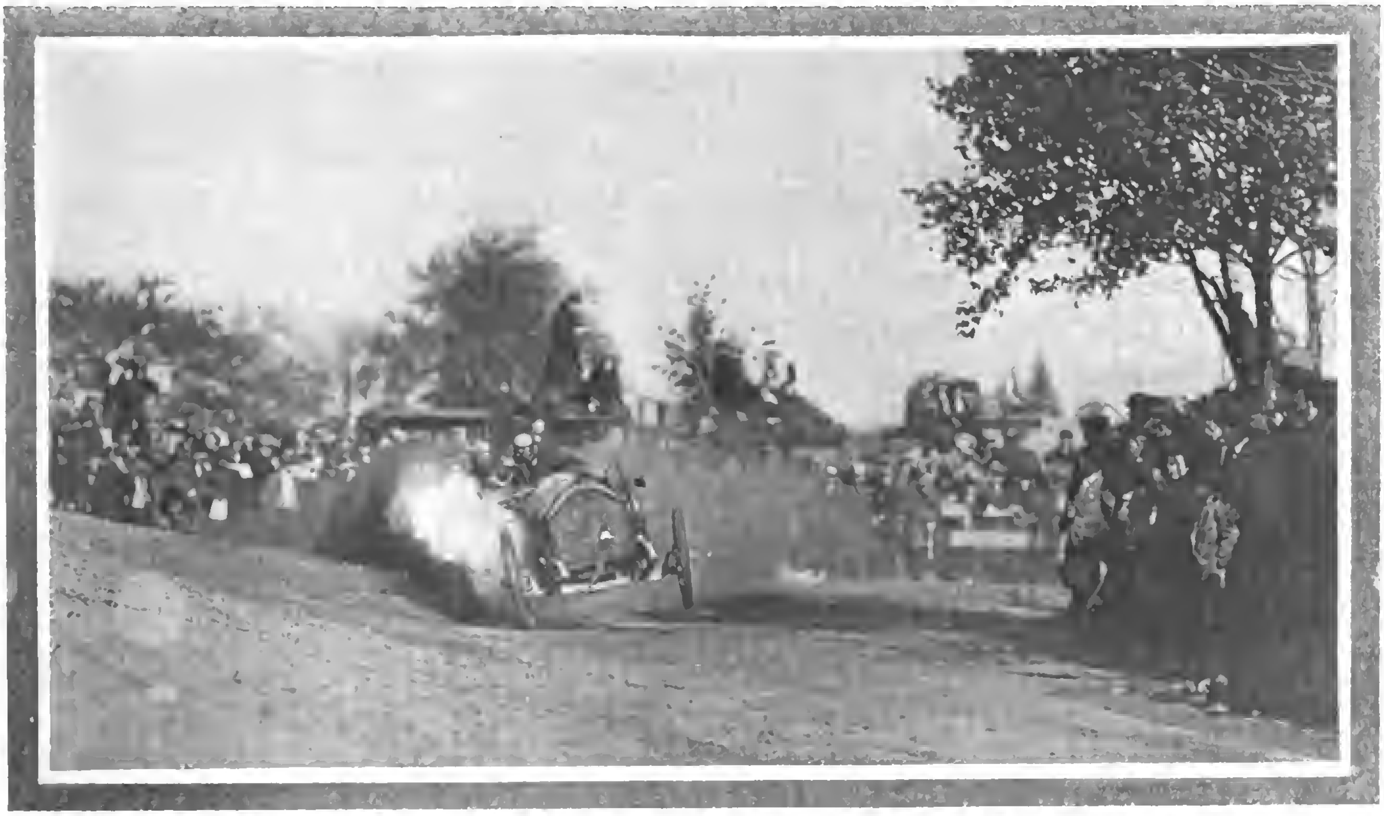
What little interest there was in the race for the Wheatley Trophy, soon died a natural death. Beginning with the very first lap, Harroun driving Marmon No. 32 took the lead and held it through to the finish, being the only one to conclude the whole fifteen circuits of the track. This runaway match was profitable for the driver, since in this race the prize was increased by a purse of $1,000. Some idea of the "cinch" which Harroun had may be gleaned from the statement that a lead of 7 mins. at 50 miles had been doubled at 100, and increased to 16 mins. at the 150 mark, which was the last distance covered by his nearest competitor. The time while not wonderful, would have put this car in fourth position, had it been in the big race.

From the point of real interest, the little car race supplied what was wanted, for two-thirds of the starters fought it out until the checkered flag stopped them. The Chalmers team, with a substitute driver on one car, early assumed a commanding lead, and ran one, two for all laps from the third to the ninth, Costello heading the list in the first previous to his disappearance, and the little Hudson, the midget of the race, edging into second place on the second and third. Unfortunately, "Buster" Brown fell by the wayside in the tenth, and the two Maxwells beat out the other Detroit car. Like the winner in the Wheatley, this winner would have been placed in the big race.

Keeping a concise and prompt record of a score of cars on a twelve-mile circuit is a bit more difficult than doing the same thing on a course twice as large. Both officials and spectators became painfully awake to this fact, for Peter Prunty had a less number of announcements to make than at any previous Vanderbilt event. Lack of knowledge of what was taking place undoubtedly had much to do with loss of interest and the departure of not a few before the conclusion. No sun found its way into the wind-swept grandstand, which did not hold its customary crowd, and no music helped to enliven the occasion.

As a matter of fact there was an evident air of economy in the air which indicated that the affair was being conducted upon business principles solely, a policy which frequently is detrimental in sports when carried to an extreme. The crowd was New Yorkish in both quality and quantity, and Society with a capital "S" that graced the occasion came mostly from the Long Island colony. Sir Thomas Lipton was a pleasing figure; John D. Rockefeller, though said to be present, escaped the camera brigade and pressmen generally; and Jack Johnson, colored holder of fistic laurels, aroused antagonism by his obstreperous presence. George Robertson watched proceedings from the pits in front of the grandstand, though few recognized the 1908 winner. Robert Lee Morrell, chairman of the 1905 Cup race, was present, but Jefferson deMont Thompson, the 1906 and '08 chairman, was an absentee, as were many other noted autoists from other cities who have seen the event in previous and more national years. Present President Gary and ex-presidents Morris and Hoyt, of the A. C. A., all whom are members of the Motor Cups Holding Company, were on hand.

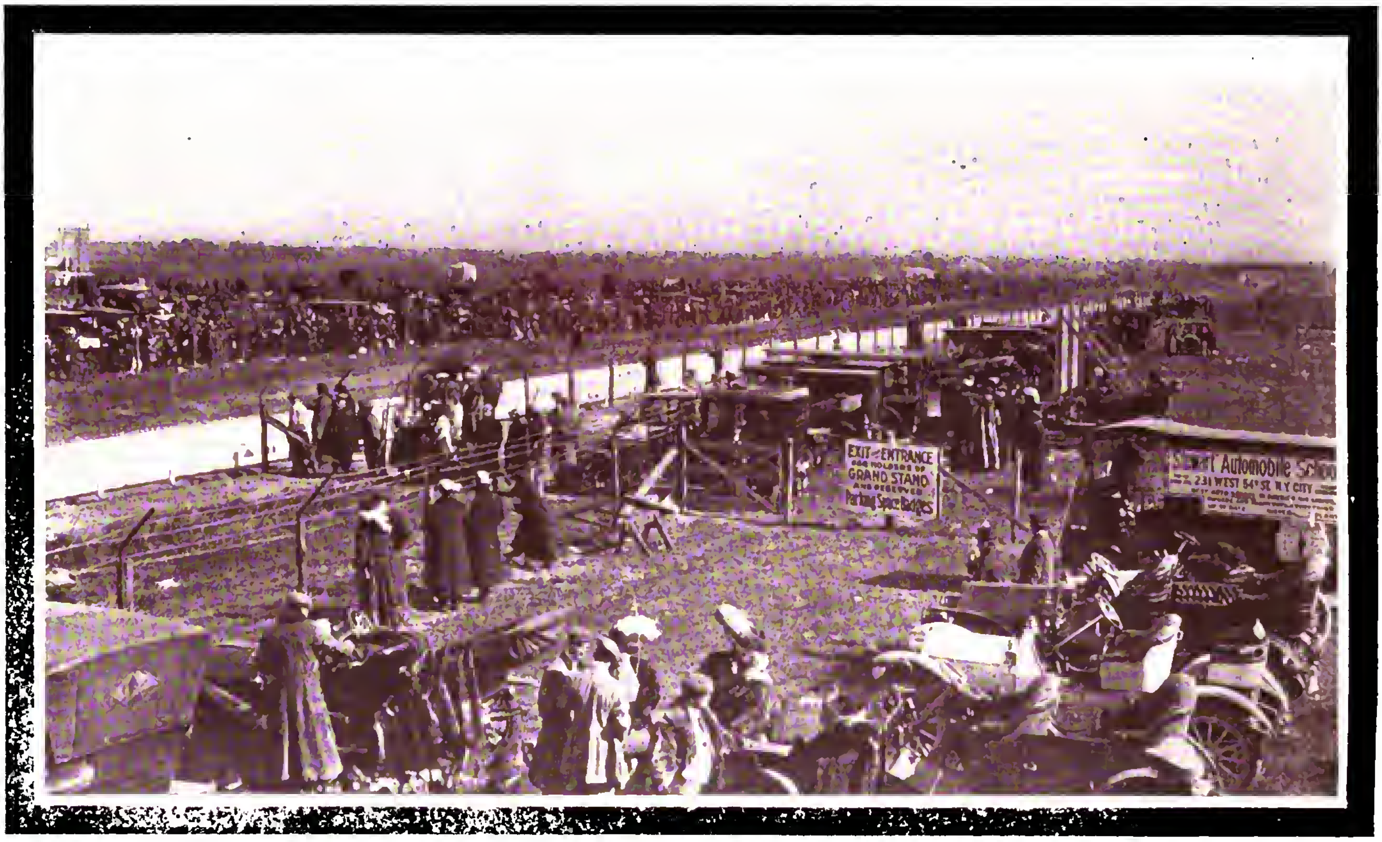
President L. R. Speare, of the A. A. A., the racing board of which has hitherto constituted the nucleus of the cup commission, attended in company with President J. T. Coughlin, of the Worcester Automobile Club, and W. E. Metzger, of the Manufacturers' Contest Association. S. B. Stevens, of the A. A. A. Contest Board; F. H. Elliott, secretary of the A. A. A.; R. Lincoln Lippitt, of the Rhode Island Automobile Club, were among the other few automobile personages of note.



Knipper in His Chalmers-Detroit Sensationally Rounding the Curve at Old Westbury Turn

THE DETAILED STORY OF THE VANDERBILT CUP

LAP 1—Of the 15 cars that started in the Long Island Classic, a 6-year-old Mercedes, driven by a 20-year-old amateur, Spencer E. Wishart, of Greenwich, Conn., was in first position at the completion of the circuit. Chevrolet, in a Buick, was but 11 seconds behind him, with 20 seconds separating him from Seymour in the Isotta, who was third. Knipper in Chalmers No. 7 followed six seconds later, and the balance of the field finished the circuit in the following order: National No. 10 (Aitken), Apperson (Harding), Chalmers No. 9 (Lorimer), National No. 11 (Merz), Marmon (Stillman), Simplex (Mitchell), Alco (Grant), Atlas (Knox), Fiat No. 14 (Parker), Fiat No. 4 Hearne), Fiat No. 1 (Strang). Strang met with hard luck, a stone crashing into his radiator and damaging it beyond repair.



Along the Finishing Stretch Cars Were Not as Numerous as In Former Years, Though the Course Was Well Protected

Lap 2—Chevrolet forged to the front in this lap, and second honors were divided between Wishart and Knipper, whose times were tied; fourth position was taken by Seymour's Isotta, and Mitchell forced his Simplex into fifth place from tenth position in the preceding lap, making the best time for the lap—10:47. Lorimer maintained seventh position with Chalmers No. 9, and Aitken and Merz in their Nationals followed. Grant advanced his Alco one position in this lap, and was followed by Stillman's Marmon. The balance of the field was unchanged. Strang made an effort to get his broken radiator repaired and again started in the race, but the effort was futile.

Lap 3—Chevrolet, Wishart and Seymour finished the lap in one, two, three order, and Knipper dropped to fourth position. Lorimer advanced from seventh to fifth position, Harding's Apperson staying sixth. The order of position of the rest of the cars was unchanged except that they were advanced a notch, the Simplex going out of the race on this round with a broken crankshaft. Hearne had considerable trouble with a broken crankcase and was at the repair pit most of the round.

Lap 4—Chevrolet made the fastest time of the race in this lap—9:56[2] for the circuit—and looked a sure winner if his speed kept up. Wishart, Seymour and Knipper kept up the chase in their respective positions, and Aitken advanced his National from seventh to fifth position, nipping Lorimer at the tape. Harding dropped to seventh place, and Grant advanced from ninth to eighth position. Merz and Stillman followed, and Parker got his Fiat into eleventh place, the Atlas and Hearne's Fiat following.

Lap 5—Three cars went out of the race on this lap, Chevrolet's Buick, which was leading; Aitken's National, and Hearne's Fiat. The first mentioned broke a cylinder near Meadowbrook, the National cast a wheel near the same town, and Hearne's Fiat went to quarters with its broken crankcase. Wishart's Mercedes led at the lap's conclusion, Isotta, Knipper's and Lorimer's Chalmers, Apperson, National No. 11, Alco, Marmon, Parker's Fiat and Atlas following.

Lap 6—Seymour's Isotta, that was in second position, broke a part of the front axle and was withdrawn. Wishart's Mercedes again led, and the balance of the field was advanced a position without relative changes by the Isotta's withdrawal.

Lap 7—Wishart's Mercedes had trouble with a pressure pipe which broke, and lost its lead, dropping to fifth position. Knipper and Lorimer advanced their Chalmers to first and second positions, and Harding's Apperson was third, with Merz's National fourth. Grant's Alco still held sixth place, and as the Marmon went out with a cracked cylinder, Parker's Fiat and the Atlas advanced one point each in position.

Lap 8—There was no change in this lap in the positions of the first four contestants. Parker secured fifth position for his Fiat by making a bit faster time for the lap than Grant, who still clung to sixth place. Continued repairs on the Mercedes placed Wishart at the foot of the column with Atlas preceding him.

Lap 9—In this lap the only change was a shift in position for the Alco, which jumped into fifth place due to Grant's steady and consistent driving.

Lap 10—This round saw the first six cars unchanged in position. The Atlas had some trouble and Mercedes regained seventh place.

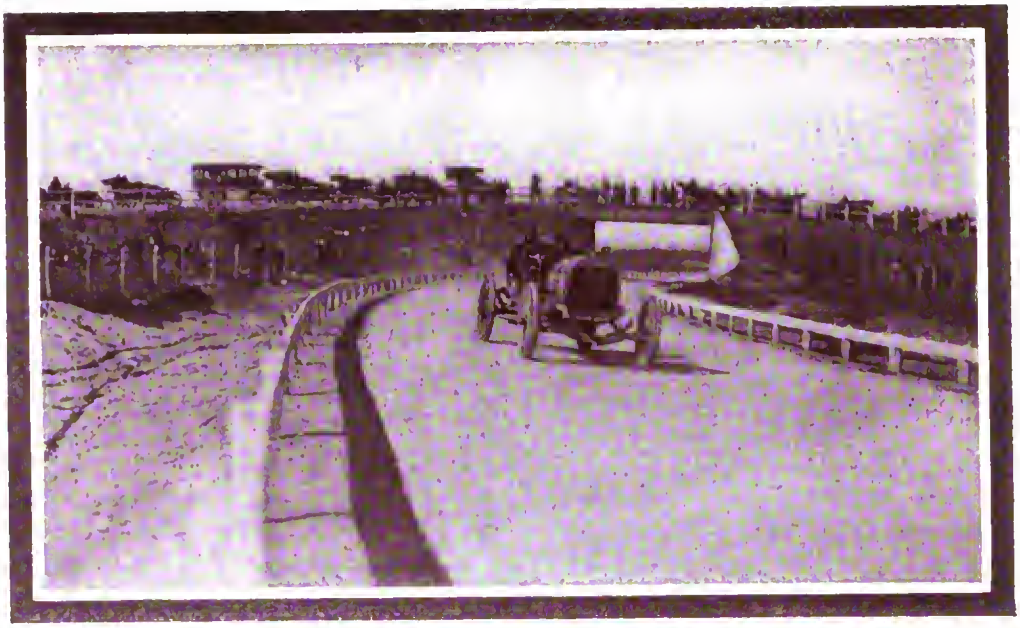
Lap 11—The official scorers evidently failed to see the Alco in this lap and did not credit Grant with it when he crossed the tape. He was unquestionably in fourth position according to the timers' computations, and everybody but the scorers seemed to recognize the fact. (As the scorers' error was corrected by the officials at the conclusion of the race, he is credited in the laps that follow with his correct position). Harding's Apperson went out on this lap with a broken steering knuckle near Massapequa Lodge. The rest of the relative positions were unchanged.

Lap 12—Lorimer gained the lead in this lap while Knipper changed a tire at the pit. Grant advanced his Alco to third position, putting Merz back into fourth place.

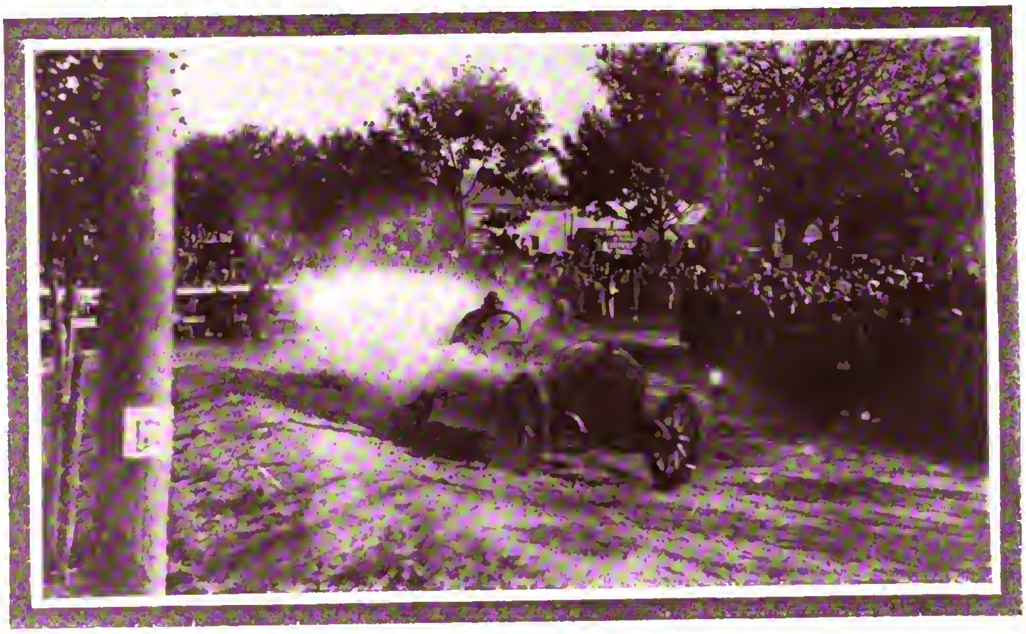
Lap 13—This was an unlucky lap for Lorimer. He broke a cylinder and was out of the running. Merz withdrew his National in this lap and the field was narrowed down to five competitors, which were lined up at the lap's conclusion as follows: Knipper's Chalmers, Grant's Alco and Parker's Fiat, closely bunched for first, second and third, and Wishart's Mercedes and Knox's Atlas trailing.

Laps 14 to 19 (inclusive)—Knipper's Chalmers maintained its lead during all these laps, closely followed by Grant's Alco and Parker's Fiat. In the 14th lap the Fiat gained a slight advantage over the Alco,. but lost it in the 15th. After that the positions were unchanged. The Mercedes and Atlas were kept going.

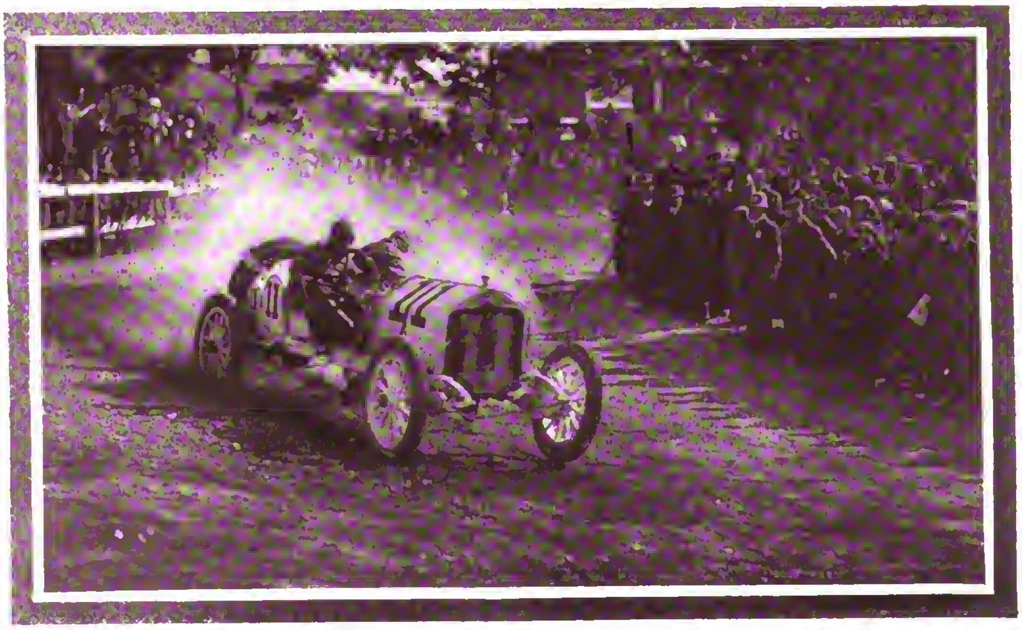
Laps 20 to 22 (inclusive)—In the 20th round Knipper had trouble wtih the lubrication of his car. There was a stoppage of oil and one of the connecting rod bearings heated up. He could not get under way again in time to finish the race. The Alco advanced into first position and maintained the lead till the finish, with Fiat a good second, and Mercedes and Atlas still running when the race was called.



Knipper Handled the Chalmers-Detroit With Consistent Skill, Taking Turns Spectacularly



Two-Cycle Atlas Attracted an Unusual Amount of Attention



Merz and the National Which Once Looked Dangerous

Score Card-Vanderbilt Cup Race-Oct 30/09 - Graphically Arranged to Show How Cars Gained and Lost Position Each Lap

EXPLANATION OF SPEED—POSITION CHART

The card shows the time in which each car finished the lap. The laps are arranged in vertical lines from left to right as numbered at the top, the first column being the start, and the position of each car in that lap is shown by its distance from the top of the column. Of course, at the start of the race the cars were in their regular order, and their numerals show in that manner. Then, as the car progressed during the race, its numeral is shown in the column of each lap, in the position in which that particular car was placed at the finish of that lap.

These various positions are connected by lines, for readiness in following a car, and it has the additional advantage of showing exactly what cars passed each other during a lap, as every intersection of these connecting lines shows that the car whose line has the greatest inclination up, passed the car or cars which have a less inclination. Thus, during the second lap, the registration of the passing will be between columns 1 and 2, and it will be noted that car No. 15 passed cars No. 5 and 10; but it can likewise be noted that car No. 11 passed car No. 5, because of the less dip of the connecting line for No. 11 than of the connecting line for No. 5.

Having entered the numbers of the cars in their order for each lap, they can then be joined as the race progresses, by the connecting lines, so that one has a continuous score at any time, showing the exact performance of each car in a graphic method and one which is very easily kept by anyone interested.

MARMON HAD IT EASY FOR WHEATLEY TROPHY

LAP 1—Four starters that got away in the contest for the Wheatley Hills trophy reached the scorers' stand at the conclusion of the circuit in the following order: Marmon (Harroun), Moon (Wells), Columbia (Wilcox), and Marion (Munson), the ultimate winner taking the lead at once.

Lap 2—Harroun's Marmon still led, and Wilcox's Columbia gained second position from the Moon, driven by Wells. Munson had considerable trouble with his Marion, and the time spent at the repair kit put him hopelessly out of the running.

Laps 3 to 15 (inclusive)—It was a virtual walkover for Harroun and his Marmon, as he was never headed or even pushed by the rest of the contestants. Wilcox's Columbia, which was in second position, was on its 13th lap when the contest ended, and the Moon withdrew on the 7th circuit. The Marion was far behind, but still running when the contest for the Vanderbilt Cup ended on the completion of the twenty-second lap.

CHALMERS HAD MOST SPEED OF LITTLEST ONES

LAP 1—Thomas Costello who drove Maxwell No. 45, led the field of six starters for the first round in the race for the Massapequa honors. Joe Matson, who piloted the Chalmers "30," finished a close second, and Ainslee, with his Hudson "20," was third. Brown, who drove the other Chalmers "30," showed up fourth at the scorers' stand, and Doorley, who drove Maxwell No. 46, was in fifth position, followed by the third Maxwell entrant, No. 44, driven by Arthur See.

Lap 2—In making this circuit Ainslee brought his Hudson "20" to the front of the field from third position. He was a shade ahead of Matson's Chalmers, which maintained second place. Brown's Chalmers followed, and was in turn succeeded by See's and Doorley's Maxwells, respectively. Costello had trouble with his motor and withdrew from the race.

Lap 3—Matson's Chalmers gained first position in this round of the circuit, and the Hudson followed closely. There was no change in the positions of the other cars.

Laps 4 to 6 (inclusive)—With Matson still leading, Brown brought his Chalmers into second position in the fourth lap, the Hudson dropping to third place, with the See and Doorley Maxwells following. These positions were maintained.

Lap 7—The only change in position was with the Hudson, which dropped from third to fifth place.

Laps 8 to 10 (inclusive)—Relative positions were unchanged, the two Chalmers leading the field, with Matson ahead, until the concluding lap, when Brown, who was gaining slightly on Matson, threw a rear wheel near Massapequa turn. The other competitors were a lap behind, but completed the distance in good order, the Maxwells driven by Doorley and See getting second and third places, respectively, and the Hudson a good fourth.

Promptly at Nine O'Clock the First Car Was Sent Away, It Being No. 43 Chalmers-Detroit, with Matson Driving

WHY IT WAS THAT SOME OF THE CARS DIDN'T WIN

NEVER in the history of the Vanderbilt Cup race has there been such a depletion of the ranks of the contestants. The strangest part also is that the lack of finishers was not due to long tire delays, in the majority of the cases, but to mechanical difficulties alone.

In proportion to their numbers the little fellows, headed by Joe Matson in the Chalmers, made the best showing. Four of them finished, and five of the six starters were running on the ninth lap. Compare this with the showing of the big cars, as well as that made by the cars in the Wheatley Hills sweepstakes. In the Vanderbilt, two cars finished and five were running at the finish. In the middleweight event, the Marmon had a walkover, and the Columbia was well in the rear, but still running.

Compare the results of the former Cup races and we find that the number of those who fell by the wayside is almost as great as the number that went by the board in the first of these classics in 1904. In other words, but 29 per cent of the cars were running at the end of the race. A partial explanation is that the 1909 Vanderbilt course, though shorter than in previous years, was a particularly hard one for the cars. It is undeniable that the surface of the parkway, when covered at high speed, subjects the cars to severe treatment—much more severe than will be met with over even average country roads.

Very little of trouble which overtook the cars could be remedied at the pits. All that met with accidents on the road could not be ascertained absolutely, but such as was confirmed will be set down below.

Briefly the causes by which the various cars were eliminated are as follows: Strang's Fiat had a broken radiator; No. 2 American broke the center main bearing and sprung the crankshaft the day before the race; No. 3 Simplex broke its crankshaft on the third lap; No. 4 Fiat, driven by Hearne, cracked the second cylinder and punched a hole in the crankcase, on the fifth lap; No. 6 Apperson turned over, on account of a broken steering knuckle, so it was reported; No. 7 Chalmers, driven by Knipper, had an air-bound oil pump so that the motor ran dry and a connecting rod bearing seized; No. 9 Chalmers, driven by Lorimer, had a piston seize; No. 10 National broke a rear wheel and also smashed the rear construction, while his team mate is reported to have suffered from engine trouble; No. 12 Marmon, driven by Harry Stillman, broke a water manifold and cracked a cylinder; No. 15, Chevrolet's Buick, also ended up with a cracked cylinder; No. 17 Isotta had the misfortune to crack a steering knuckle, due, it is stated, to taking a ditch in attempting to pass the Alco.

So much for the Vanderbilt cars, and now for the smaller ones. "Buster" Brown, who was driving the Chalmers, on his last lap and in second position, had the rear axle break, and when the left rear wheel dropped off he was out of it; No. 5, Costello's Maxwell collided with a tree on the second lap; No. 31, a Marion, took from 10 to 30 minutes each lap to replace inlet manifold gaskets. The fate of neither the Columbia nor the Moon could be ascertained at the grandstand.

Observed at the Grand Stand Pits

Several interesting episodes took place at the pits. Interest waned considerably as the stops became less frequent and the number of contestants smaller. However, the reason for the various stops at the pits and the time lost at each may prove of interest. First to stop at the pits was Hearne in the Fiat. The motor was missing badly and the spark plugs were changed. Next to lose time was the Marion No. 31, spending 5 1-2 minutes replacing inlet manifold gaskets. No. 34 Moon lost two minutes on the fifth lap taking on two new tires. Immediately after the Isotta came down the course on its sixth lap very slowly. It was soon learned that a steering knuckle was bent and cracked. In close order came the Marmon No. 12, which required 1 1-2 minutes to fill up with water, after which it failed to show up again on the seventh lap. On the third, Marion again stopped for inlet manifold gaskets; otherwise, the car was running nicely.

Grant on the sixth lap pulled up at the pit to have two tires changed. Grant must be credited as being the coolest and most collected of the drivers in the whole race. Even though 15 minutes behind the leaders, at one of his stops he appeared no more hurried than if he had been as much ahead. It was with this very attitude that he took the opportunity to clean his spark plugs while waiting for the tires to be changed. Altogether 4:45 minutes were taken to put on new tires and clean the spark plugs.

At this juncture the Fiat No. 4 drew up at the Fiat pit, on the fourth lap, and when the hood was raised the reason for his slow approach was clearly evident. A 4-inch hole was punched in the lower cylinder wall of the second cylinder. In addition the crankcase had been crushed open. All were indications that a connecting rod had let go. No. 6 Apperson on its fourth lap stopped at the pits to tighten up the clutch, which seemed to be slipping; 2:45 minutes were required in all.

No. 16 Mercedes, which up to the seventh lap had been holding a good position, was forced to stop on account of a broken pipe from the reducing valve to the gas tank. An attempt was made to repair it temporarily with tape, but the frequent stops afterward proved that young Wishart was unsuccessful. Next to stop was Knipper on the Chalmers. A right rear tire was replaced and the tanks were refilled, 2:15 minutes being required by the change. Wishart, with the Mercedes, stopped on his eighth lap for 35 minutes to do more work on the broken pipe. No. 31 Marion again made a stop for the same reason.

About this time Strang appeared again, just completing his first lap. The second lap was never attempted, for the timing gears had not only made a hole in the cover, but also in the radiator. On his tenth lap Grant in the Alco made a second stop, to put on a new front tire and filled up his tank, 2:45 minutes being required. No. 31 had now begun to stop regularly each lap to put in new gaskets. No. 16 followed suit, and continued operations from lap to lap, working on the air pipe to the gas tank. Only 20 minutes were lost this time, and in addition two fresh tires were put on front. Knipper stopped on the tenth lap to change a right front tire, which was accomplished in 1:20, being one of the fastest changes made at the pits. At this juncture the report came that No. 5 Atlas was off the course, and this was confirmed by the two slow laps which it made, its tenth and eleventh being 37 and 42 minutes, respectively.

On the eighteenth lap, Knipper, who was leading the Alco by nearly ten minutes, had to stop to put oil in the crankcase since that in the supply tank could not reach the motor. Seven and one-half minutes were lost in this work. His failure to stop on the next lap for another supply resulted in the seized bearing. Despite this fact it was reported that the motor was again running, but the race was called before the car could finish the lap.

On the fifteenth lap the Atlas stopped for more oil and gasoline. The motor was kept running the entire time of the stop and a peculiar phenomenon was always evident. The motor was of the two-cycle variety, and when throttled down would miss and exhaust an explosive mixture into the atmosphere. This gas would then be set off by the exhaust from another cylinder. The effect of the explosion was not felt near the car, but at a distance of about ten feet from the exhaust pipes.

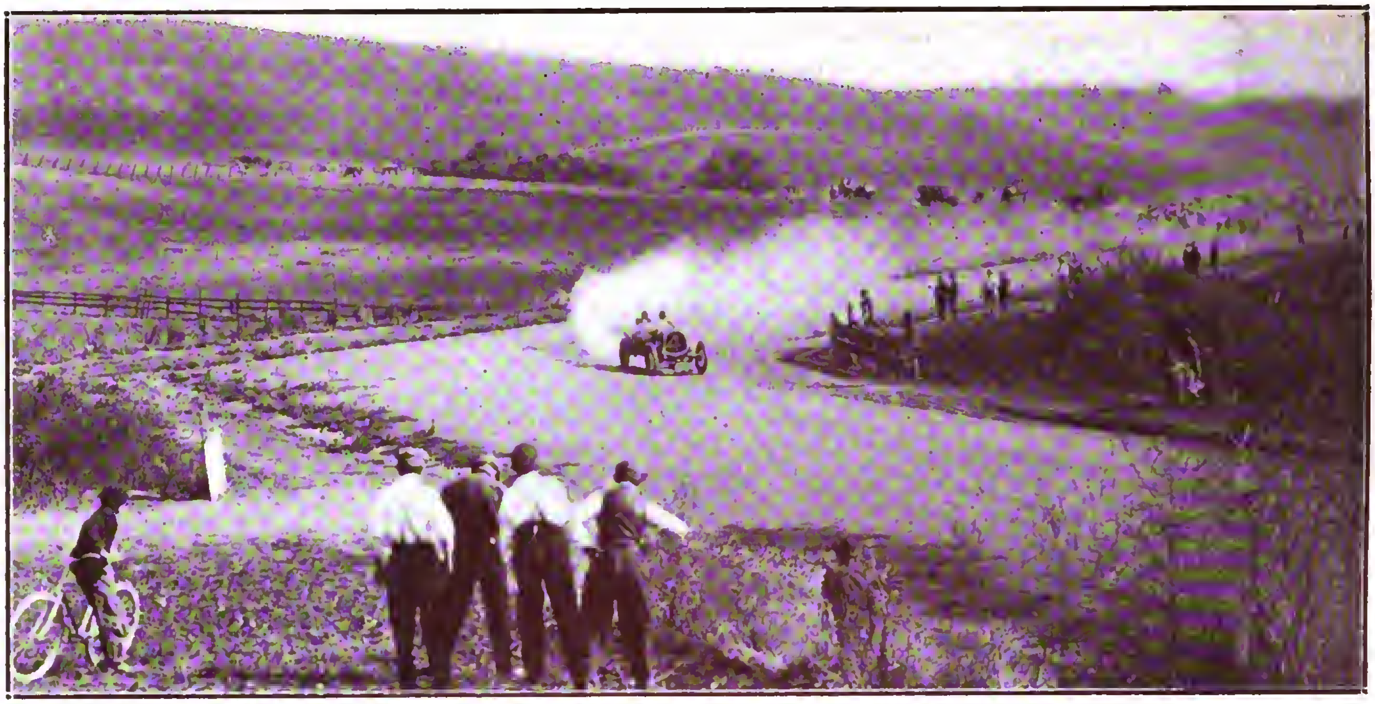
The last man to stop at the pits was Wishart in the Mercedes, and since the race had been called off he made no attempt to start again.

Tires, Magnetos and Oil of the Winners—The three races showed consistent performances for well-known makes both of magnetos and tires. Michelin scored first and second in the Vanderbilt and first in the Wheatley Hills and Massapequa Sweepstakes. Grant's Alco, Parker's Fiat, Harroun's Marmon and Matson's Chalmers-Detroit all depended for their shoeing on the tire made in France and New Jersey.

The magneto question brought forth a similar unanimity, although the nationality favored was German, also well Americanized. The vital sparks on Alco, Fiat, Marmon, and Chalmers-Detroit were generated by Bosch armatures revolving within Bosch magnets, timed by devices of the same make; and Bosch especially proved its merit on the six-cylinder Alco by turning one-and-a-half times engine speed and producing three sparks on each revolution.

In lubricants the chief victory goes to Harris oil. Grant chose this brand to "soothe the worrying cranks" of his Alco, and apparently his judgment was vindicated by the perfect satisfaction it gave on the 278-mile course, keeping the mechanism in condition for the final four-lap spurt at 70 miles an hour. These four successive rounds, in 10:49, 10:43, 10:58 and 10:33, clinched the race by opening up a five-minute gap on the nearest rival, and proved the perfect condition of the car at the finish.

Leaving the Parkway and Taking to the Country Road Near Westbury—Arthur See's Maxwell in the Foreground



Fleming in the Pope-Hartford Making His Way Around the Wiggle Turn, Considered Very Dangerous

ALMOST A RECORD AT PORTOLA RACES

SAN FRANCISCO, Oct. 25—This section of California has had its first real road race, and it was a "hummer." At first, it was thought that the Western as well as the American distance record had been smashed, but a remeasurement of the course showed that it was much shorter than had been thought. Consequently, the time was not quite as good, and the record was narrowly missed. At that, the West has done some very fast racing, fast enough to make people "sit up and take notice." As recorded in last week's issue of THE AUTOMOBILE, the big race and the little race were both won by Jack Fleming driving a Pope-Hartford, while second in the longer distance and first in the middle class were the prizes won by Henshaue's Apperson Jackrabbit.

FASTEST LAP OF EACH CAR IN PORTOLA RACES

No.	Car and Driver	Piston Displacement	Lap	Time	M.P.H.

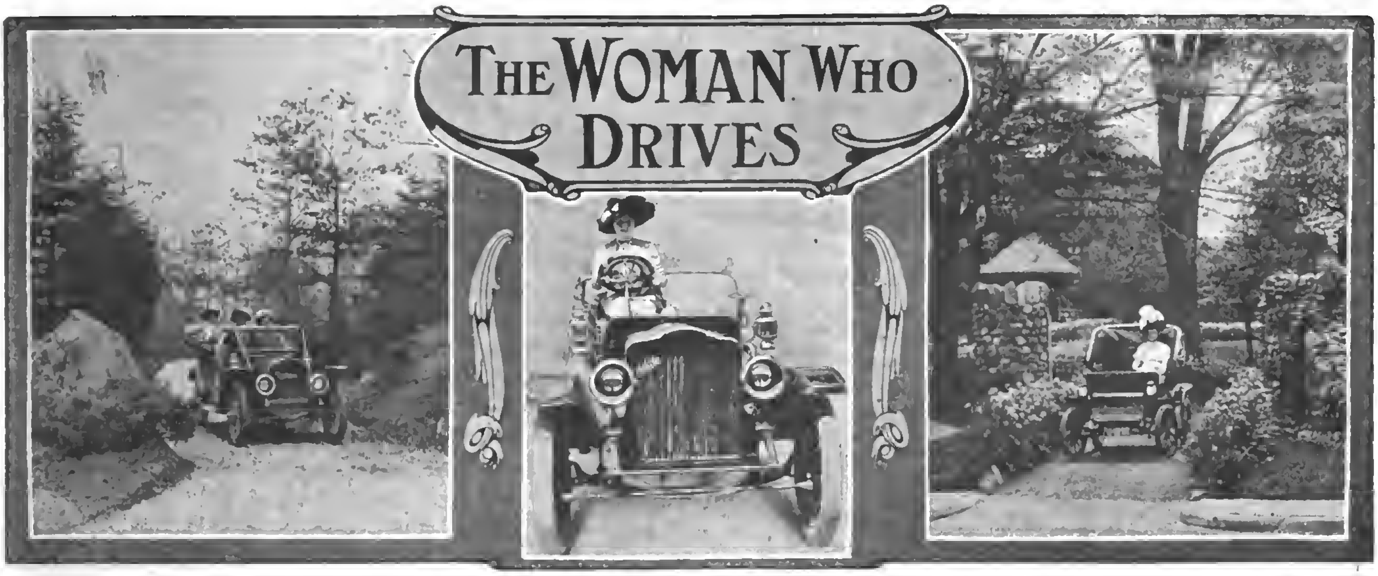
The Woman Who Drives



IN the last generation not one woman in a hundred did anything outside the four walls of her own home; to-day, on the other hand, there is hardly one in a hundred who is not interested in some form of out-door sport or recreation. A woman driving her own automobile forms no unusual sight at the present time and attracts scarcely passing attention.

Every woman who drives should become thoroughly conversant with the mechanical part of her car and should be able to overcome the ordinary troubles which may arise. Each, too, should prepare herself as far as possible in guarding against troubles which are likely to occur even with the best motor.

The chief obstacle in many cases when a woman wishes to become a skilful and independent driver is her own nervousness. She is continually anticipating troubles, instead of giving her attention to a systematic study of her car with a determination to succeed and overcome the ordinary troubles which may arise.

Another type of woman automobilist is she who considers that she "knows it all"; who, because she can manage the steering wheel, which is the very easiest of the many things to learn, and with only a superficial knowledge of the parts mechanical, considers herself a really competent motorist. She probably learns how to remove and clean a spark-plug and a few other of the smaller details, and then goes driving about the country thinking herself capable of making a repair if needed. When the time comes, however, she quickly learns her mistake; she either finds herself dependent on the aid of some passing autoist or else sends for an expert and so confesses her ignorance.

Which is more to be pitied from the automobiling standpoint —the woman who is ignorant of the essential features of a gasoline motor on account of a nervous indisposition to understand it, or the woman with a shallow smattering of things mechanical which she flatters herself is all-sufficient? Certainly, neither of them is competent to drive a car unless accompanied by an expert. That they escape trouble is simply due to good luck and most decidedly not to any mechanical knowledge they possess.

What the Beginner Should Learn—Every woman who contemplates driving a car should make it her aim and ambition to learn the working features of the motor, to familiarize herself with the different parts and know what should be done in cases of emergency. It is necessary to use one's head much more than one's muscle.

Many little things must be learned by heart before one can become a really competent driver.

Test the batteries occasionally; see that the spark coil buzzes in tune; keep the spark plugs clean and see that the current passes through them; never allow the motor to run without lubricating oil or to become overheated; don't try to run the motor with the water circulation shut off.

Neither should the motor be over-lubricated; blue smoke from the exhaust is the sign of over-lubrication, and black smoke shows that too much gasoline is being consumed. Both cause sooted spark plugs and dirty valves.

Gasoline should always be strained before being put in the tank, as the merest trifle of dirt or grit is sufficient to clog up the carbureter. There are some troubles that cannot be guarded against, but dirty gasoline is one thing that should never be allowed to cause annoyance.

Always avoid allowing the motor to race, but keep it at the speed at which it runs most efficiently. All useless revolutions of the motor when it is running idly are many moments loss of its life, not to mention an unnecessary waste of gasoline, lubricating oil and bearing metal.

There is an economic and pleasant speed for every engine, just as there is for a living person, a speed at which a person can walk and run without taxing the muscles or destroying the tissue of the system. So with the piston of an engine. In the duty of an engine, driving the car and running light are two entirely different conditions. When working, the engine has the flywheel effect of the car behind it; it is backed by a ton of metal in motion with itself, and so is held steady.

Running light, on the other hand, has nothing to balance it except its own comparatively small flywheel. Therefore before declutching one should throttle down the engine, and before starting throttle down to the point where the engine will most easily take hold.

Never draw up with the brake if possible; it wastes tire rubber every time it is done. Instead, withdraw the clutch in anticipation of the stopping point and just make the standstill with the brake.

Distinguishing the Good Drivers—Skilful driving does not consist of running at high speed close to vehicles or other obstacles and then jamming on the brakes to avoid a collision. When driving in town—or anywhere, for that matter—if there is ever any doubt whether the car can get through, don't try it.

Don't go near the pavement too suddenly, for a deaf person or one engaged in other thoughts may step off in your path.

When passing a car head on, blow the horn loudly enough to reach the ear of a person walking across behind the other car. Always go too slow rather than too fast.

Some women understand the construction of a gasoline motor well enough to take it apart and put it together again, but of course there are many women to whom working around machinery covered with oil and grease is too distasteful ever to allow them to get much practical knowledge in this respect.

When the average woman of intelligence makes up her mind to become possessed of the necessary knowledge it does not take her long to develop into a careful and successful automobilist who can enjoy the pleasures and benefits of the sport.

Ceylon "Where only Man is vile"

THERE may be other nations as gracious as the Japs in their treatment of foreigners, as considerate of the feelings of the stranger within their gates; if so they have managed to keep their identity carefully concealed.

One bright morning we took a car in Yokohama—a Ford, by the way, of the earliest vintage, but which the owner assured us was the best ever—and started for Kamakura, a naval station some miles distant on the bay. The road was none too wide and at one point we encountered a huckster's wagon, built like our oldtime two-horse drays and drawn by a lumbering bullock. Through intent or oversight, the driver had backed his cart across the road in such a manner that it was impossible for us to pass. Stopping the car, our chauffeur got out to assist the huckster in turning around, but the bullock took fright at the puffing of the automobile and backed abruptly into the ditch, dumping out everything there was in the cart. It was a most unfortunate occurrence, and we got out intending to make out apologies to the huckster.

Did he curse us? Did he invite us to take a thrashing at his hands? Did he threaten to have us arrested as the average American would? He did nothing of the kind. With a deprecatory wave of the hand he bade us refrain from lamenting. Then, to our astonishment, he poured forth the most profuse apologies, begging that the "honorable gentlemen" might pardon such a worm of the earth as he for having gotten in their way. Every time we started to say anything we were checked by a fresh outpouring of apology, the peddler not even seeking to right his cart until he had offered numberless regrets couched in the humblest terms for an accident in which, as a matter of fact, he should have shared none of the responsibility.

But if the Japanese are models of politeness to foreigners, they have no trouble understanding each other in the event of an altercation. One day we unwisely decided to abandon motoring for the time being, and, securing one of the only two carriages available, drove about Tokio behind a spirited team guided by a nearsighted native who was far from being an expert with the reins. He had a penchant for turning corners with two wheels of the carriage in the air, and after one such effort the horses plunged through the front of a barber shop, playing havoc with the flimsy structure. We proposed stopping and compensating the proprietor for the loss sustained, but Katsuyama, our guide, would have none of it, assuring us that as our destination was only a block or so away he would remain and fix matters up.

"Give him five or ten dollars, enough to fix his shop up again," was our parting injunction.

A little later Katsuyama and the barber, both chattering wildly and with much waving of arms, came down the street surrounded by a crowd in which were several policemen.

"What do you think," stormed Katsuyama, when we had forced our way through the crowd to his side, "the greedy devil refuses to settle."

"How much did you offer him?" we inquired in unison.

"Thirty-five cents," replied Katsuyama, fairly burning up with indignation. "and he wouldn't take it. He wanted more, the greedy devil."

He got more, too, in spite of the vehement assertions of our guide that he was a robber. Thereafter we stuck to motoring or to rickshas.

Katsuyama furnishel little or no cause for complaint, however. A Japanese guide gets a commission on every purchase made by members of his party, and he is always on hand to collect it. Whenever we entered a shop, to which Katsu usually piloted us, however trifling the purchase, he would call the proprietor aside and in his blandest manner inform him that he was Katsuyama. That settled it, Katsu pocketing his commission in the most matter-of-fact manner.

All this was legitimate, however, and on the road Katsu proved himself a wizard in many respects. He had the most wonderful lunch basket imaginable, and in producing delicacies therefrom displayed all the dexterity of a magician. When we halted by the wayside Katsu got the "honorable" hot water and brewed us each a bowl of the most delicious tea. Then from that marvelous basket appeared in order cups, saucers, plates, knives, forks, spoons, napkins, cakes, biscuits, jam, potted meats, fruit, "tan san" water, and, if wanted, Scotch and soda. Had we called for hot toast there is every reason to believe he would have fished it out from the innermost depths of that seemingly inexhaustible basket. Katsu was a wonder, and it was with sincere regret that we finally parted company with him.

Auto Still Attracts Attention in Japan

In spite of the general progressiveness of the people, an automobile is still a *rara avis* in Japan, attracting universal attention whether in the city or out in the country. Japan has not taken the road question seriously as yet, at least so far as making provision for automobiles is concerned. The highways are for the most part ordinary, in many cases being positively bad for all save native carts and rickshas, which everybody uses.

However, you soon forget all about the roads, so interesting are the sights encountered. Not the least of these are the children that make every village a human ant hill. They line roadway, grave visaged little brownies, and stare solemnly at the strange looking equipage as it puffs along. Wee tots, mere babies themselves, have still smaller ones strapped to their backs, often fast asleep, with their poor little heads bobbing about in a manner that threatens dire results to their necks. A little thing like weight appears to be no handicap to these sturdy youngsters, and it is a common sight to see a child running and playing with another half as large strapped to its back.

They are a quiet race, but seem to extract a deal of fun from life, and there is always a smile and so much politeness.

The ride from Yokohama to Kamakura is delightful, the road part of the time skirting the sea and again running through farming country and villages where the air is literally filled with kites, great big red and black fellows, soaring about and presenting a most grotesque appearance.

Kamakura has many famous temples and other buddhas, the greatest of which is the Diabutsu, a bronze buddha fifty-seven feet high, set in a grove of very ancient pine trees. It is also a naval station, and you are not allowed to take photographs there. However, there is nothing to prevent getting one of the priests to take them for you.

Japan a Joy to the Traveler

Aside from its lack of good roads, Japan is a joy forever to the traveler. On every hand there are little tea houses, exquisitely appointed, where the daintiest of Japanese maids serve you with tea, stand at your side and endeavor to carry on a conversation in their quaint "pidgin" English, and puff industriously at your cigarettes.

The artistic sense of the Japanese is everywhere apparent, but its highest stage seems to have been reached in the location of these tea houses, with their arbors of wistaria and the little settees scattered about in the shade. They are "toy" houses, and the furnishings and people correspond to a nicety.

Japanese civilization is much older than our own, which may account for some of the customs that obtain. It is a trifle disconcerting to have a Japanese maid come pattering into your bedroom just about the time you have discarded those articles of apparel prescribed by the dictates of polite society in your own country, and blandly ask if you are in need of anything. Likewise, for the first few times you fail to appreciate the thoughtfulness of the girl who noiselessly slides into your room, prepares the water for your bath, and remains to see that your ablutions are properly started. They think nothing of it. In many of the hotels in small towns there are few if any doors with locks, merely panels that slide back and forth, and the "bellhops" enter and leave at will. They don't believe in doing two things at once, these quaint little maids that are employed in all hotels, with the result that there is a constant pitter-patter of sandaled feet, and a regular procession of attendants with your "honorable" hot water, or after your "honorable" boots or something else. In the morning before you arise they serve you with tiffin (lunch), and the last thing at night they are on hand to see that you are comfortably settled. They are a decided improvement over the average American or European bellboy.

A room in a Japanese hotel is designated by the number of mats on the floor. You can get a four-mat, a six-mat, or any sized room you desire. Often that is about the only thing they contain. At Onimichi there was a little tea house whose doors and ceilings continually interfered with the altitude of a man from the Occident, and where the four-mat room was just what its name implied. At night they brought out a double portion of quilted mattress, with a quilt nearly a foot thick for a coverlet. Fortunately the house stood on the edge of the sea, and as they pushed back the paper windows, thus admitting plenty of air, it was possible to sleep without suffocating.

If Japan's roads are a disappointment, which, however, is more than offset by the exquisite beauty of the country, its flowers that beggar description and the courtesy of its people.

Ceylon's Highways Were a Surprise

Ceylon's highways prove a distinct surprise. Never outside of Massachusetts and one or two other Eastern States have we ever found in America such splendid roads as traverse "the isle of spice." In Colombo they are of macadam, made from red stone that gives a decidedly pleasing effect. You are limited somewhat in the matter of motoring, owing to the size of the island, but every foot of it is well worth seeing. The cars found here are mostly of English make, the one we employed being an Argyle, powerful enough but rather old-fashioned and by no means up to the standard of present American makes.

Three days are required in doing the island, about one hundred and fifty miles being covered daily, although a week or more might be spent to advantage in this manner. From Colombo to Putalam, a government "rest house," which you reach early in the afternoon, the road skirts the seashore. From there it leads into the interior, winding through the jungle. Monkeys entertain you with their antics in the trees, and once a jackal slid across our path, but aside from this the jungle was no worse than the thick woods to be encountered almost anywhere in America, while the roads were so fine as to be almost disappointing.

Anuradhapura, one hundred and twenty-five miles from Colombo, and the turning point for motorists who return to Colombo by way of Kandy, is a delightful spot, the rest house being set in an old garden of banyan trees, with jasmine, roses and lilies.

The sacred Bo tree and Rock temple are points no tourist should overlook. It is worth a long journey to see the solemn-visaged high priest who holds a screen before his face while he pronounces a blessing upon you, and then, attired in the gaudiest of robes, takes a gigantic key and with measured tread leads the way to big brass doors in the rock where a buddha, carved out of solid rock, sits contemplatively viewing the surroundings.

The Hottest Place on Earth

Penang is another place where you can motor with comfort, that is, unless you are desirous of taking a comfortable bath afterward. The cars in use here are of an ancient type and not quite powerful enough, but Penang is one of the most interesting places imaginable. The bath? Instead of the diminutive tin tubs that are made to do service throughout most of the Orient you find a huge earthen jar, holding twenty gallons or more of water, with a tin dipper attached. Divesting yourself of your apparel, you stand on the cement floor—about the only cool thing in Penang—and pour water over your head and shoulders, letting it trickle down over the body.

The roads running out from Penang are as near perfect as could be and lead through tropical forests, past plantations of pepper and cocoanut, with all manner of palms, and with flowers overrunning everything. They say Penang is the hottest place on earth, Aden not excepted. Perhaps it is, but you are not required to exert yourself here. Nobody does, and with a motor car, plenty of servants to do everything for you, and such magnificient roads and scenery, Penang proves an ideal spot.

When You Go to Singapore

Unless you have taken a motor ride with Joe Constantine, famous the world over as manager of the Raffles Hotel, you have not done Singapore. Joe knows every point of interest that can be reached with a motor car, and in his company you forget that Singapore is but a degree and a half above the equator, and that the breezes come from "the mouth of hell." A moonlight ride about the city and its environs in a motor car is an experience never to be forgotten.

Bombay and Calcutta have automobiles in abundance. On the other hand, when you reach Hong Kong it is to find that the few autos there are owned almost entirely by private individuals. We had the rare good fortune to take several rides of short duration, but that was the only place in China where we found any automobiles; nor did we encounter any through Japan until we reached Yokohama.

From an American car of the present day to the antiquated machines found in the far East is a far cry. On more than one occasion we wished that we might encounter a live American who possessed a real machine in these lands where there is so much to see and where one accustomed to getting about expeditiously is often sorely tried by the leisurely Oriental methods.

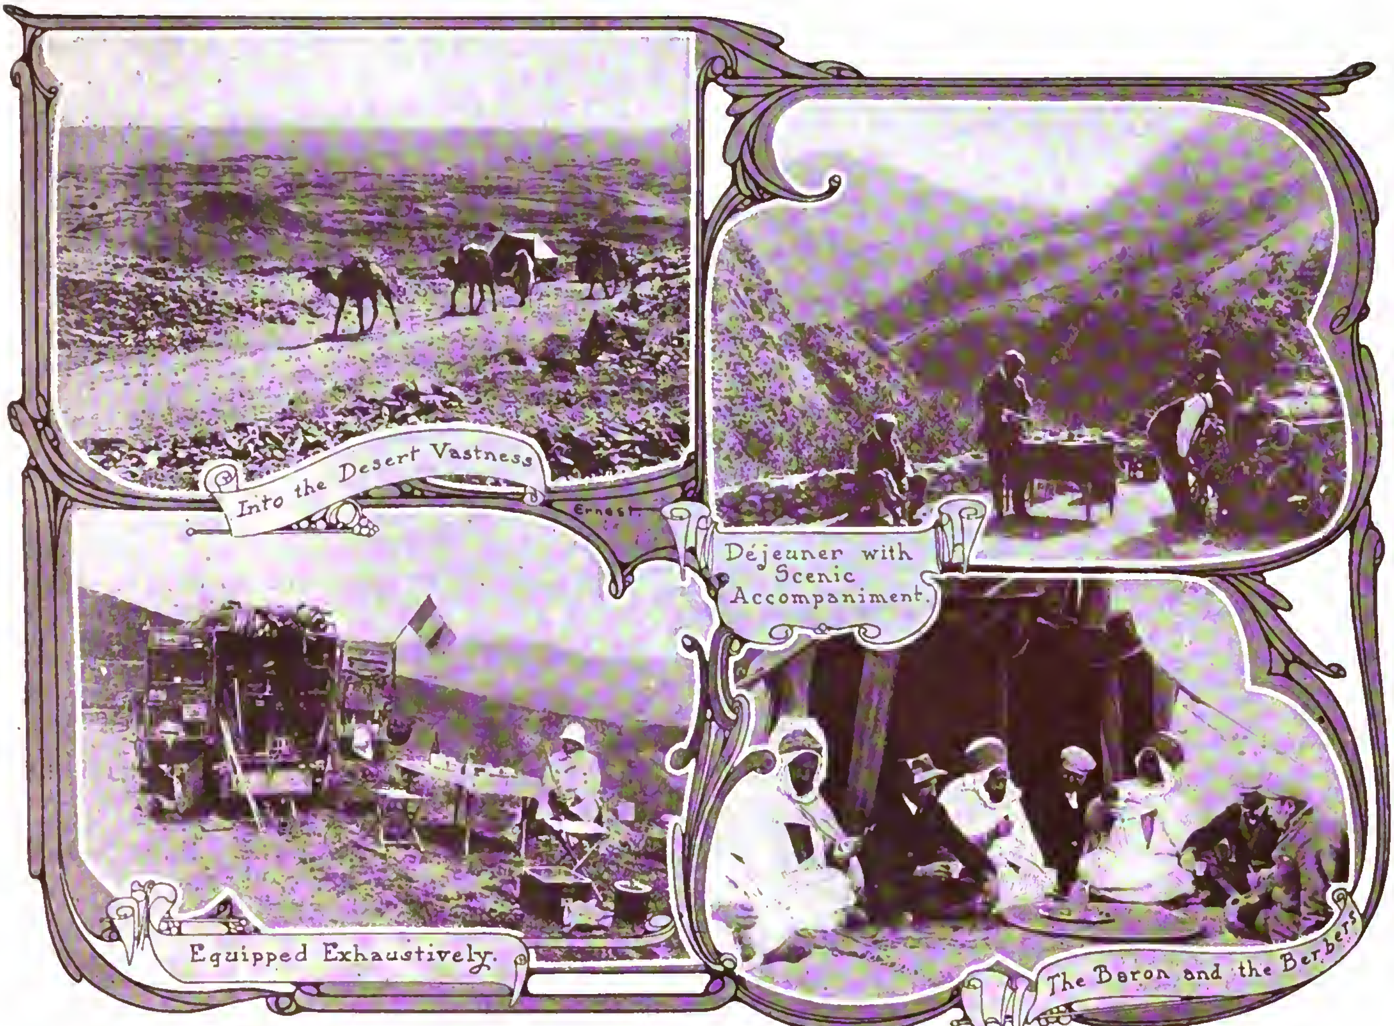
BEST ROUTE WASHINGTON TO RICHMOND

CONSIDERABLE diversity of opinion has existed as to the best route between Washington, D. C., and Richmond, Va. Officers of the Gordon Motor Company, of Richmond, which concern has been very active in the Virginia good roads movement, announce that the following route is the most desirable:

WASHINGTON—	
16.9	Fairfax
23.6	Centreville
31.0	Manassas
36.4	Bristow
49.1	Catlett
55.1	Calverton
60.0	Midland
68.2	Remington
71.3	Elkwood
73.9	Brandy
77.2	Inlet
80.0	Culpeper
89.9	Crooked Run
98.0	Madison Mills
101.0	Orange
110.7	Gordonsville
117.0	Green Springs
120.2	Trevilians
124.8	Louisa
135.0	Cuckoo
142.6	Jackson
178.0	RICHMOND

Recently, C. C. Hildebrand, sales manager of the Stevens-Duryea Company, covered this route with a "six," in company with Gordon company officers. Mr. Hildebrand calls attention to the progress in roads building in Virginia, where J. E. Pennypacker, of the office of public roads of the Department of Agriculture, has been aiding in a vigorous campaign. Quoted in a Richmond paper, Mr. Pennypacker says:

"America is entering upon a great era of road-building, and other States than Virginia are in the van. Other States are spending millions, where Virginia is spending thousands, and to keep abreast of the general progress she must bend every energy to the task and do it quickly. Virginia has wonderful possibilities as an agricultural State—every product of the temperate zone is possible to her farmers, and all at a profit. Twenty million urban dwellers are at her threshold waiting to buy. Good roads constitute the "sesame" which will unlock the treasure."



AFRICAN TOUR OF A BELGIAN SPORTSMAN

Baron Pierre de Crawhez ranks among the "Old Guard" of Continental automobilists, and in the early days of the sport won considerable distinction as an amateur driver of racing cars. He is president of the sports commission of the Automobile Club of Belgium and president of the Automobile Clubs of Namur and Luxembourg. Although a Belgian, and nominally a resident of Brussels, his address is usually, as he would say, "*partout.*" Recently he has been touring in Algeria in a specially equipped car which made him quite independent of civilization. The ingenious arrangements by which every emergency is forestalled make an instructive study. The baron penetrated the Atlas Mountains, through which the French have built many of their famous roads, and made several excursions into the Sahara Desert. Game of many kinds, both feathered and fourfooted, is abundant there, and the natives as a rule are law-abiding and inclined to assist the traveler. The region is as yet rarely visited by automobilists.

FOR 1910 PRINCE HENRY TOUR

BERLIN, Oct. 15—At a meeting of the Imperial Automobile Club and the Society of German Motor Car Industrials, the preliminary regulations for the 1910 Prince Henry tour were laid down. It was decided to run the contest on German territory only, and to hold it from June 1 to 8, with Berlin as the start and Homburg as the final stage.

The itinerary is as follows: Berlin, June 2; Brunswick, June 3; Cassel, June 4; Rothenburg, June 5; Strassburg, June 6; Coblence, June 7; Homburg, June 8.

Two speed trials, both on the flat, will be held, the first on the opening day on a route between Geuthin and Magdeburg, and the second to wind up the event on the Taunus course.

A new formula will be worked out for these races, but the very superfluous, because circumvented, handicap of last year will be dropped. All vehicles of 8 to 25-horsepower are eligible. The minimum weight to be 77 kilos, with an additional 25 kilos for every horsepower over eight, exclusive of spare tires, of which at least one must be carried.

There are great changes in the management of the I.A.C., as Herr de la Croix, the general secretary, has withdrawn from his post, Rear Admiral Rampolt having been elected in his stead. Herr de la Croix remains, however, on the representative committee in place of the late Dr. Levin-Stoelping.

RECENT FRENCH TRADE STATISTICS

The French trade statistics for the first nine months of 1909 afford very interesting reading compared with those of the same period of 1908, as they show a very considerable increase in the sale of both American and English cars in France, coupled, in each case, with a drop in France's return business, which, in America's case, shows a decided slump. The figures in pounds weight run as follows:

Exports 1909 Lbs	Exports 1908 Lbs.		Imports 1909 Lbs.	Imports 1908 Lbs.
300	1,000	Austro-Hungary	73,300	27,500
2,500	200	Argentine	461,000	334,100
400	——	Algeria	551,100	372,000
75,500	78,100	Belgium	1,428,800	877,700
——	——	Brazil	103,600	169,300
83,400	39,000	England	4,852,600	4,871,400
166,700	218,500	Germany	781,600	935,400
118,300	112,300	Italy	236,300	162,700
——	——	Russia	366,800	286,000
51,200	21,500	Switzerland	251,500	168,700
12,400	4,500	Spain	264,800	241,600
——	——	Turkey	44,700	49,200
42,700	8,100	United States	646,100	875,500
7,000	4,400	Other Countries	794,100	746,700
560,400	487,600	Pounds	10,856,300	10,117,800

GOING SOME OR AUTOING OVER FIGURATIVE ROADS

By S. Ross

AS paint or polish is ofttimes used to conceal defects, so does a certain figure of speech allow things designated by it to parade under false colors. Most of the wagon roads in southwestern Washington rank as such merely by courtesy of the hyperhole. while the hills are really hills hy divine right of unmolested geology. Of Seattle to Portland I wail, and "awfully" tired, if not equally disgusted, will be the autoist who essays the trip.

Considering the roads, "going some" might apply to my first day's traveling, though my odometer marked up but 130 miles. And, aside from a slow leak in a rust-cracked inner tube, which I repaired in 40 minutes, I had no mishap the first day. The 130 miles meant beyond Toledo, Wash., a small town on the Cowlitz River.

The then possession of the experience since gleaned would have led me to accept the advice of the White Steamer man, who, at the Cowlitz ferry, on the morning of my second day, urged me to camp in the shade of a large sycamore on the river's bank and ship by steamboat to Portland the next morning. For on the second day my mishaps seemed to have set in with vim and vengeance. From Seattle to Chehalis, a distance of 98 miles, the roads are very good; but 14 miles south of Chehalis one strikes the hyperbolic roads—gawky travesties on the name of respectable highways—routes that bespeak not of a citizenship of empire, but of slothful creatures who are "down shod to care" and who infest the crags. Something needs injecting. The last half of the road from Chehalis to Toledo is mostly planked, with divers planks missing or criss-crossed, and rough corduroy and pools of mud interspersed.

I made the trip in a two-cylinder, 12-horsepower runabout of the best grade, and marvelous it is what steep hills the little Autocar wonder climbed. Each cylinder seemed trying to outdo its mate, so well balanced was the commutator. Truly there are no hills steeper anywhere, and well-regulated communities will not tolerate hills as steep or rugged. Then there were several bridges which I had to cross on low gear at lowest speed—bridges of poles and logs heterogeneously conglomerated.

12 H.P. Autocar Beating 35 M.P.H. on Natural Macadam

Over Decadent Planks—Divers Planks Missing

Through Tumwater, Oldest Settlement in Washington

Through Pheasant and Grouse-Habited Forest

It is only slightly figurative to say that many of the hills have the tilt of eggs we order fried.

At a small town called Napavine (the first syllable would well suffice) I took a boy's word, got on the wrong road, and soon ran into over three miles of the roughest corduroy in the world before again reaching the main road. In the restrospect, my trip seems one unbroken spell of mishaps. After starting to the Cowlitz ferry he second day I missed the road when but 200 yards from the ferry, and went over three miles and return over the roughest road of my journey, except the above-mentioned corduroy.

Five minutes after ignoring the advice of the White Steamer man I had a small blow-out, caused by using an old casing too highly inflated. Getting the bull-dog slugs to let loose, and putting on the extra tire of my equipment, required a full hour's work. It was eighty something in the shade and I worked in the sun. These troubles conspired with a loose radiator hose to prevent my going more than 8 miles by 2 p. m. of the second day. Yet I deserved the trouble caused by the leaky hose, for I had had notice, as runs the phrase imputing negligence, on a previous run, of the insecure clamp and its hair-trigger propensity to drain my radiator.

Seven miles from the ferry I passed the upturned (then righted) car of Prosecutor F. J. Heney, which had rolled down 20 feet of a fresh sandy fill-in. A pile of fir boughs lay across the lower end of this embankment, and one of the twigs struck the underhanging stop-cock of my radiator and let all the water out by the time I had reached a bridge 200 yards beyond. Being without a bucket, I had to empty my carbides on a newspaper and twice clamber down 100 feet of a precipitous, densely undergrown gorge to get water enough to prevent my engine from overheating before I could reach a more accessible supply. Then, before I had gone a stone's throw, the pleasant road jarred the loose hose completely off the radiator pipe and spilled all the water I had lugged up from the ravine. I smiled not, nor was I silent, and my language vouchsafed no relationship to

Job. By what I then thought the kindly ministration of some overseeing power of compensation, I soon found a small pool in a quiescent brooklet, and from it I filled my tank. I put as tight a garter on the radiator's hose as I could with common wrapping twine. I have since learned many of the pronounced uses of hay wire, and will hereafter carry a good supply in my repair kit.

Near the town of Castlerock I came to another hill of the erectness of fried eggs. It was corduroyed, and among the transverse poles was a log 8 inches higher than the poles. With the low gear I poked the front wheels over the log, then opened the throttle some to get the rear wheels across, and the thud of the car as the rear wheels crossed choked down the engine. The hill was so steep that the log would not scotch the rear wheels while I let out the clutch to crank the engine. In preference to backing down the hill and making the whole ascent again, I backed diagonally into the bank at the side of the road, rolled the log out of the road, started up my engine, and managed to reach the top by letting out the clutch and on the brakes when the engine threatened to choke down, about every 4 feet. I had not gone half a mile from this widely known hill when, as a result of the incessantly rough jarring it had received, the copper bar which connects the units of the spark coil parted, broken in twain. At a nearby house a kindly frau helped me find a piece of galvanized wire, which I bent into a connector for the units of the coil.

I then had fairly decent roads until within a few miles of Kalama, where I struck a hill of marvelous erectness. An obtuse biped in the form of a contractor was grading the road to eliminate a steep, boulder-strewn hill there and had graded away the approach to the old road so that wagons and automobiles, alike, had to climb, if they could, a 40-degree slope to reach the highway. After delivering a brief philippic against any one, mutt or fool of other degrees, who would put a road in such condition I went in quest of the county commissioner, who lived in the small town. In this officer I found a man of discernment and good-roads spirit who put "five strong men," as Beaucaire says, to grading down the bank. With these five men pushing I climbed "straight up" to the old road.

For the next 12 miles I paralleled the banks of the Columbia, except when the railroad required all the valley between the river and the jutting hills, and then the wagon road was left as a thing of meagre concern to find its way as best it could over the ridges primevally marked out by geological processes. With no further trouble, other than a constant refilling of the tank, I reached Woodland at the close of the second day.

On account of high water in the Columbia River making the nearest ferry over the Lewis River unapproachable (though I tried it and got stuck in the mud for 90 minutes), I had to go eastward seven miles to the other ferry, the one at Etna. Risking the redundancy, I must say that the old ferryman there was truly a good samaritan from Altruria, for he furnished a piece of good hose and helped me fasten it non-leakably in place of the pestiferous one which had lost me five hours out of two days, and for a compensation which would little more than tip a garage employe for cranking one's engine. This dispenser of blessful aid also directed me how to avoid the worst hills between there and Portland. The route recommended was through View and Lewisville, and about 12 miles longer than the usually traveled road by way of Lacenter. Yet I had trouble enough with two hills, having to scotch the rear wheels and start the engine several times, to the tune of blistered hands, ere I reached Vancouver at 8 p. m.

It eventuated that I was not to be singly visited with radiator troubles, for the violent jolts of the roads by courtesy had so often thrust the water tank against the flywheel just beneath that a hole was worn through the tank, causing rapid loss of water therefrom. The radiator was thus emptied and my engine choked with heat when I reached View, a town easy to see, with its one store and no dwellings. There a young man in charge of the store (it was Sunday) brought out his soldering irons and made a fire to heat them while I took off the tank. We soldered a piece of tin over the hole and thinned portion, after I had so concaved the bottom of the tank with my foot that it could not again evince any affinity for the flywheel. Another envoy from Altruria had, in extravagant phrase, saved my life, and for what I felt was too small a recompense after I had paid him twice the amount asked. After 27 miles more of "good roads," on which I broke the leaf of a spring, I reached Vancouver just as a three days' and nights' downpour of rain set in. Late in the forenoon of the next day the rain vanished into "Oregon mist," and I went the seven miles of smoothly planked roads and paved streets into Portland. Then the rain lavished itself upon the earth till newly cut hay began to rot and the enormous, unequaled cherries of that clime to crack open on the trees. For three days the newspapers urged the weatherman for a change and the weatherman bulletined "Fair," but the rain ignored the program and kept coming as from an "exhaustless urn"

At 3 o'clock in the afternoon of the fourth day since the rain began I found the roads fairly dry and good as far as Salem, Ore., a pretty and prosperous little countrified city with wheat fields within its limits. The city was in its "glad rags" and heyday mood having its annual cherry fair. Doubtless no finer display of cherries and berries was ever got together.

Just south of Salem the next morning I found very good roads, and from worthy reports that the same kind of highways led practically all the way through the State, I was expecting a fine ride to far south of Eugene that day, when the most prolific source of a motorist's troubles belched forth a liberal supply. My carbureter set up a noise like a pair of cats trying to blind one another with saliva. The pump joined the chorus and failed to circulate the water, causing the engine to overheat and knock. I managed to get back to the garage in Salem, where both of the

One of the Beautiful Waterfalls Encountered En Route afflicted parts were overhauled. The pump was choked by a wad of leaves from the water I had poured in unstrained a few days before. But no evidence of disorder was visible in the carbureter, its secrecy remaining to cause the most serious trouble of my whole trip. I then started south again, but when I had gone the same three miles which I had made on my first start my carbureter spat like a Dowie flock of cats, and the engine would not budge the car, except on the low gear. I again turned back and in rampant disgust, and got "fixed up" by a good citizen who was a good mechanic, but who overlooked the salivated carbureter. As soon as he let me loose I "hiked" for Portland, hoping to there take a boat the next morning for Kelso, a town on the Lewis River just above the Columbia and about one-third the way from Portland to Seattle. I expected to make the return trip in two days, as the boat would reach Kelso about 1:30 p. m., and I had almost made Kelso from Seattle in one day. But I was told in Portland (on Friday, the day of blessings) that the boat would not leave for Kelso until Monday. Being determined not again to drive the road to Kelso, I remained in Portland, while it rained, until Monday, when the boat loaded three automobiles for Kelso. Two young men with a Studebaker and myself went ashore at Carroll, six miles from Kelso, and were in Kelso a full hour ahead of the boat. Crossing the Cowlitz River at Kelso we found the road very good to some distance north of Castlerock. Here my recurring troubles took a fresh start. My car balked on a hill of easy grade. I tested out all connections and found that both cylinders were firing well enough, but that the left cylinder would not run the engine. After more than an hour's probing for the trouble's throne (for the ailment was king), a family of three came along in a touring car southward bound, and the man and son, in their goodfellowship of the road, spent another hour helping me to ascertain that about a third of the left exhaust valve had broken off. Detaching it, I rode with the accommodating family to Castlerock, where I took the ferry across, the family continuing south to Kelso. The only machinist in Castlerock did not have his lathe set up and informed me that I would have to go to Kelso to have a valve made. If on time, the train for Kelso would have gone 15 minutes before, but, luckily (once) for me, it was an hour late. I took the train, engaged the well-equipped machinist in Kelso to make a valve, went to supper, which I was too fatigued to enjoy, returned to the shop and got the valve after a short wait, bought a ticket for return to Castlerock on the first train, waited in the depot until it came at 2.30 the next morning, reached Castlerock at 3 o'clock, rowed across the river in a boat I managed to detach from the ferry and walked nearly four miles to my docile car by full daylight.

With oiled emery powder I ground in the new valve as best I could, inserted it in place, then had to spend nearly an hour getting the machine from the slippery fern patch on the road. After some five miles of smooth going a wet red hill put a check to the steadiness of my speed. After three attempts on low and four on reverse gear I climbed the hill. The next hill, a few miles beyond, was still steeper, with the steepest part corduroyed and a stream of more power than grandeur trickled over the logs, causing my rear wheels to spin. At a nearby house I borrowed a shovel and bucket and carried gravel and dry dirt until the road was so that the wheels would take hold.

I had no more trouble with hills, for after about twenty miles of road, embracing bumpy corduroy, mud holes and deep sun-baked cattle tracks for most of the distance, the carbureter gave forth a belated Fourth-of-July sound, and both cylinders were without compression. The trouble was beyond my power to diagnose, so I at once sought help in the form of a wagon and team to tow me 14 miles to Chehalis. Expressing my willingness to pay well for it, I found a farmer with a light wagon and good team who let his son tow me over 14 miles of splendid road while I sat with one hand on the steering wheel, the other holding a handkerchief over my mouth and nose to shut out what I could of the dust. It was a lovely ride; but I persuaded myself that I was—sure to get where I started this time.

The mechanic at Chehalis found both washers jarred off the intake valves. This was done by the carbureter's holiday activity. That and a loose engine part was all the trouble he could find. Still the carbureter kept its secret like a Mason. After a night's good rest and good meals (the first since Portland), I started for Tacoma. When half the way and going well, but with diminished power of the engine, a rear wheel picked up a ten-penny nail head first. Two lads helped me spend over an hour trying to pump up an inner tube in which a broken spring, stowed in the car with it, had bitten a hole as big as a bean. I then started on a flat wheel to run five miles, but stopped and put in another extra tube. As a passenger from there to Tacoma I carried a man who had rendered some assistance and whose presence was a desirable offset to the likelihood of more trouble, for "croaking" points were getting numerous.

We made Tacoma at a good speed, and at my passenger's house we *enjoyed* a good dinner, and I left for the 41 miles to Seattle. As I reached the long hill about seven miles out of Tacoma my carbureter again got miserly with its gasoline, and I had to climb most all the way on low gear. After crossing the hills I discovered that the tire which I had inflated a few hours before was flat. Its flatness had likely caused the hard pulling up the hill. Caring not a whit for tires or any of the other adjuncts of my Pandora's box car, I went the next seven miles on the low gear and flat tire. Having expected to reach Seattle by 10 p. m., I crawled into Auburn, almost half way, at 12:30 a. m.

By 11:30 the next morning I had patched an inner tube and so adjusted the carbureter that I could run on the high on the best level roads. Then, when within one mile of the condensed-milk town of Kent, the carbureter put a quietus to the engine, the while I rested and ate a box of strawberries bought from the Jap pickers there. Cranking my engine, I ran but 100 yards when the gasoline gave out. By telephone I got a mechanic to bring a supply from Kent and we went in on low gear to his garage. Taking off the carbureter and pouring it full of gasoline, he ascertained that the cork settled too far down on the valve spring—that the cork was log-soaked, as he termed it. He so bent the spring as to overcome the trouble, and I came the 18 miles into Seattle at a rate that our Legislature recently declared an inhibited speed.

So ended the trip.

"Gone Some" would apply to my car, pocketbook, and self. Oh, the checks I drew; Oh, the gold I "blew" bringing my runabout through those ways called roads.

As a pleasure jaunt, of course, the trip was not worth while, but as an argument of the need of good roads—half-decent roads—it was most convincing. And here's a wee hint to automobile makers: A good road from Seattle to San Francisco would do more than oceans of advertising to insure motoring its share of popularity in this domain, and is quite a necessity to that end.

KENTUCKY CLUBS WORK FOR BETTER ROADS

Louisville, Ky., Nov. 1—In line with the growing sentiment all over the South in favor of better roads is the local automobile club's strong stand for State aid in highway construction. The roads in a large part of Kentucky are in very poor condition and badly in need of repair. Under the present laws this work is left to the individual counties, many of which, especially in the mountainous districts, are too poor to devote any considerable sum for the purpose.

To remedy this state of affairs, the Bosworth-Wyatt amendment has been proposed, and will be voted on Tuesday. Its purpose is to remove the constitutional obstacles to the appropriation of State funds for road-building. The amendment has been indorsed by commercial organizations and a practically united press. In response, to a letter from Senator Bosworth, who is president of the Kentucky Good Roads Association, resolutions in favor of the amendment were adopted at a special meeting of the board of directors of the Louisville Commercial Club, and the Louisville Automobile Club is, of course, in favor.

Building a Motor Parkway

How The Way Is Cleared

A Narrow Road Near Smithtown

Near Central Islip

Parkway Near Smithtown

EASTWARD the Motor Parkway will ultimately reach as far as Riverhead, if it does not actually go to the extreme eastern end of Long Island. For the present, however, the plans call for its construction as far as Lake Ronkonkoma, to which point the land has been secured. This vast undertaking is one which should interest others than those immediately concerned with it, since the work will be so thorough as to make it, when finished, a model for road builders of the better class all over the world.

In a great work of this character, the difficulties to be overcome are many and various; the necessary financial work preparatory to the actual raising of money must be completed; the money itself raised, land obtained at the least possible price and with the least possible friction; roads to cover this land planned; contracts let, and work started. Beyond all that, there are many petty points to be cared for in the letting of the contracts, the prosecution of the work and in many closely allied things.

More than all this, it is important that the contracts go to those contractors who will prosecute the work with the greatest vigor, since, in the present work at least, the element of time enters to a large extent and it is desired to finish the work as at present planned in the least possible time. So the contractor must be selected with this idea in view as well as from a full consideration of his ability to put onto the work the number of men and teams to push things along as swiftly as is desired. When all this has been done, and followed up continuously so as to make sure that the good work will continue, the road is in a fair way to assume shape as such.

The position just sketched out is the one in which the promotors and management of the Long Island Motor Parkway finds itself in to-day. The pictures above give some idea of the work as it is being pushed adong. To depict this in words as well as the pictures above would be to tell an interesting story.

Much of the ground which the parkway is to traverse is now covered with timber, tall and stately, if not actually virgin forest. This must be cut down, but since the land owned is but a narrow strip, a little more than the width of the road, care must enter into the cutting of this timber. The reason for this is not alone the value of the lumber, which the trees represent, but also the matter of trespassing on another man's land.

Then, when the trees have been removed and disposed of, the roots must be pulled out of the ground, so that the latter may be run over and plowed up by means of horse-drawn gang plows. This removal of the stumps is no easy task either and one in which some element of danger enters, for frequently dynamite must be used to get out all of the stumps and roots.

Back of the teams which grade and fill come more teams with broken stone, from which the real foundation is made. This is spread on roughly by wagons, after which gangs of men spread it to accurate levels. The first appearance of self-propelled machinery is noted at this stage, with the appearance of the huge and ugly rollers. They roll the leveled stone to pack it hard.

Wire netting is spread over the surface of the rolled stone to act as a binder. Then the large moulds for the cement must be constructed and set into place to limit the movement and extent of the nearly-liquid cement until it has set.

Coincident with this must come the appearance on the busy scene of the mixing machinery for the cement, as this work is not economical when done by hand. This would seem to close the story, but the cement must set, after which the molds are to be removed and bad spots, if any, in the surface must be removed or filled by the use of grout, which is but cement in a very thin liquid form. The cracks between the adjoining blocks of cement are similiarly filled, so that the whole finished surface is as smooth as the proverbial billiard table.

The second section of the Long Island Motor Parkway was opened to the public on Nov. 1. The new section is about half way between Broadway on the north side of the island and the Jericho Turnpike in the center. Its general direction is east and south, and is nine miles long, which, with the eleven miles previously opened, makes the total completed length of the parkway twenty miles. The new western entrance of the parkway is located opposite Deepdale, W. K. Vanderbilt, Jr.'s estate on the Great Neck Road. The parkway is being extended to the east from Bethpage Lodge, the present eastern terminus to Lake Ronkonkoma, a distance of thirty-two miles, on which a force of 400 men is employed. This latter portion will probably be opened next Fall, and will complete the entire distance of fifty-two miles, as now planned.

THE PATRON SAINT OF AUTOMOBILISTS

By FRANCIS MILTOUN.

MASCOTS and good-luck emblems have chiefly been wanting among automobilists. The writer had a friend who lived in Paris and went in for motor boating on the Seine, who had a Greek bronze of Narcissus which he had incorporated into a figurehead for his boat. It was a dainty sentiment, but incongruous. Still less does the automobile to-day, a sort of a cross between a decapod locomotive and a submarine (certainly no one will say that an automobile has really beautiful lines) lend itself to symbolic embellishment.

The Chenard-Walcker models for this year have had an eagle with outspread wings, cast in bronze, capping the radiator inlet, and the Royal Automobile Club of Great Britain and Ireland grants its members the privilege of having their radiator stoppers cast in the form of a royal crown, while the German Emperor has a similar emblem topping off the lamps and other accessories of his luxurious Mercedès and Benzes. But, all the same, it is forcing things a bit, like the gaudy red paint and brass trimmings of the before-the-war locomotives in America.

These interpolations are as nothing compared to what certain soi-disant patriots from America touring in France sometimes perpetrate. I have seen, at Aix-les-Bains, a "Teddy bear" as big as a Newfoundland dog perched on the canopy top of a big touring car; and a couple of square yards of American flag streaming out from behind is no unusual sight on the cars of those insatiate mortals to whom notorious conspicuousness is fame. Needless to say, they will pay for their fun when it comes to settling up their accounts, whether it is in souvenir post cards at two sous apiece—which every one else buys for fifty centimes a dozen—or cocktails at thirty sous—which is only a little Vermouth poured out of a bottle, with a dash of bitters in it—the same that a Frenchman at the next table gets for forty centimes.

One thing is perhaps permissible, and that is the adoption, if one chooses, of the inconspicuous plaque now so frequently seen on the dashboard of an automobile in France depicting the good Saint Christopher at his traditional occupation of safeguarding the traveler on his way. It is a pretty custom and in keeping with the spirit of things. The plaque, in bronze, silver, or silver gilt, costs anywhere from ten francs to a hundred and was originated by a "Boul' Mich" jeweler of the Latin Quarter, from whence so many things of taste come into being.

We are "traditionalistes" all of us, say the French, and we are, no doubt; each of us has his favorite legend, motto or saying, and, though the holy Christopher may have little or nothing to do with the mechanism of an automobile, he, of all the saints in the calendar, has ever been the best friend of travelers. Saint Fiacre could not be especially favorably disposed toward travelers setting out on a journey by automobile, and Saint Peter, with his ever-present sharp-pointed stones, is too suggestive of destruction of tires. Of Saint Clou (*quel horreur*) we will not speak; and Saint Denis, who lost his head, is the last person to be taken as an example by a chauffeur. There is, to be sure, Saint Eloi left, who was a blacksmith; he might be useful at times, fault of a better, but he was of a doubtful sobriety. In brief, then, Saint Christopher, by every right, is the ideal saint for the automobilist.

Saint Christopher is the ideal traveling companion; he never complained; he never spoke, except on suitably-called-for occasions, and, above all, he brought good fortune and timely aid to the weary traveler. All hail, Saint Christopher!

Transferring Trout from the Automobile Tank to a Can in the Epicurean District of Paris.

In an epicurean district, such as the Etoile quarter of Paris, freshly caught fish are a necessity. Unfortunately, trout streams and breeding beds cannot always be located near large cities, and although fish may be plentiful it is difficult to deliver them in the center of the city with all the freshness demanded by refined tastes. The railroad is far too slow for this class of work, for the Etoile clientele not only demands its fish fresh, but alive. The automobile, therefore, had to be requisitioned, and has very successfully solved the problem by bringing a daily supply of live trout from streams one hundred miles away to the doors of the fashionable hotels and elegant apartments of the Etoile quarter

THE AUTO AS SEEN BY THE MAN FROM KANSAS

By E. S. Graham

NO final word about the value of the automobile will be said until the people of the Middle Western States have risen in their places to address the chair.

Among them, of course, with his accustomed modesty and shrinking timidity, will be the man from Kansas—this citified countryman, this countryfied townsman—who, like the sunflower "the badge of all our race," equally at home in city street or country roadside—not only looks with unblinking eye at the sun of progress, but turns occasionally to observe the landscape.

This man may speak some day on the previous question, and not in flower language either. His words ought to have some weight, for out here in Kansas are all conditions favorable to the working out of the automobile question; long, straight roads, interminable distances, an out-of-doors worth while, and a people not only predisposed by heredity and cultivation to gadding about, but given to commercializing their pleasures. E'en

> "Though on pleasure bent
> He had a frugal mind."

It is not surprising, therefore, to see automobiles in great and ever increasing numbers scudding along our paved and tree-arched Kansas streets and past our league-long fields of corn and wheat.

"If that machine had a yoke of oxen and a tar bucket it would look like an old-time prairie schooner," said a pioneer.

"Prairie scooter, you mean, Grandad." "That is what she does, any way," was the answer. It voiced the case.

In justification of these remarks reference is made to the following extract from a report of the Kansas State Tax Commission, published in the Topeka *State Journal*, Aug. 3, 1909:

"In going over the lists of personal property in Kansas it was found this morning that at the present time there are 4,516 automobiles in the State. Last year the taxes took in only 2,156 cars. The value of the autos this year is stated at $2,619,300 compared with only a million last year. One of the surprising facts is that most of the motor cars of the State are owned in the central and western counties, and the farmers are at the top of the list."

But does there not exist in the West any prejudice against the automobile? Naturally, yes. Prejudice, prayer, and profanity have been the running mates of public carryalls on their first trips since man ceased going afoot. These vanished, however, with the convincing of the people that the vehicles were safe, pleasurable, and useful.

Steamboats passed through the days of scared and praying negroes on shore and swearing mate on deck unto eminent service to valley folk. Locomotives have long since tooted past —where, pitchfork armed, upon the right of way

"The embattled farmer stood"

—to comparatively safety and pleasure in railway travel. To quote a train advertisement: "He who rides may read" at dollars and dollars per read. May even ride, read, sleep, dine, or die simultaneously. Pay the porter, and he does the rest.

But this new machine of ours, called variously as you ride in or jump from before it, "a buzz wagon," a gasoline "buggy," a "joy" or "devil wagon," this automobile—has it no foe? Yea, truly, like the old-time prairie schooner it has a Man with a Musket. Unlike the old-timer he does not ride, but takes aim at the flying machine from the roadside fence. Prejudice? Yes. Prejudice a plenty everywhere against the automobile.

Why? Three reasons. First: the automobile has been heretofore too exclusively a pleasure vehicle; not a useful one. Second: it has become the greatest death-dealing machine in the world. Third: the absolute indifference of some drivers to the fate of persons injured.

What must be done? Three things: The auto must be adapted to the business uses of a busy people, as well as to the pleasure excursions of the idle rich. It must cease to be a "battle wagon." Last and, consequently, Western people must be reconciled to its universal use.

Nature has already done much to adapt her subjects to the demands of the auto. Our old hens have developed wings on their feet—Mercury-like, that they may rise to the occasion, so to speak, when caught red-handed—or red-footed, to be more accurate—in following their occupation of running for rods down the road ahead of the machine, the chauffeur of which, too far from his Presbyterian church to get out his letter, that he might do full and complete justice to the occasion, is swallowing to the point of explosion all sorts of unsayable things. Playful Western puppies are learning to respect the auto, and so seldom do they annoy the passing auto with that postlude of thrilling yelps with which ancient Fido went to his untimely reward.

Our respectable farm horses no longer indulge in unexpected comic valentine antics at scent of gasoline. The pedestrian, too, is acquiring eyes in the back of his head.

We all know that many of the evils referred to are passing, or never existed, in the West. We all know, and are very glad to say, that no more considerate, intelligent, free-hearted man ever took his neighbor out to ride or stopped to pick up a hurt puppy in the road than our average Western autoist. Long life to him, say we! May his gasoline never give out, may he bowl gaily up the hill of life, and coast softly down the other side into the garage of serene old age!

But before he goes we wish to speak to him a minute. He has some work to do, this man whose wealth, power, and influence are counted with his generosity.

Here is a part of it: If he would see public prejudice against his class entirely disappear, he must assist us in controlling the speed maniac—the man who, perfectly safe and considerate while driving the family Dobbin, is transformed at touch of brass lever into a "high gear" fiend, indifferent alike to the rights on King's Highway of trundling babyhood, jogging old age, or walking poor. This man must pass from our midst, and our good autoist should assist at the demise or transformation. The published statement of a Western motor club that would assist in detecting and prosecuting its own members who violated the speed limit is a case in point. Public prejudice disappears rapidly under such treatment.

Our good autoist has still another chore to do, if he would totally disarm public prejudice. His machine has been used too exclusively by pleasure seekers to make it popular with those to whom leisure and pleasure are denied. The toiling, digging public has unwittingly confounded the innocent auto with its laughing, sometimes jeering, pleasure-seeking burden.

What's the remedy? Set this great, upholstered, insolent-horned fellow to doing the world's work. Let the auto haul and peddle and pull loads; then will the people shake its lever with a brother's grip and accord it peerless precedence on the highway. Another case in point is that of a Kansas farmer. His auto is a part of his working outfit. In it he goes to market, to mill, and to fair. Little prejudice exists in his community against the auto. Little prejudice would exist anywhere if the machine were not only the people's pleasure car, but their business vehicle as well. We wait the early day.

Another way in which this good autoist, to whom we referred several miles back, may serve his State and self is in organizing State-wide motor clubs, such as are enjoyed in other countries, the members of which are devoted to touring the country over a finely constructed and popularized system of good roads.

What the Universal Use of Good Roads Would Do

As this is not a report of the Roosevelt Country Commission, only two effects will be given here. First—Sectional differences would be overcome. If oil men would take a run through the short grass country, if corn men journeyed thus through the wheat belt, it might not take half a session of the State Legislature to perfect an organization and get down to *legismaking*. Second—These good roads and the universal use of them would do more than anything else to break down the barrier between city and country life. Away with that invisible, unreasonable thing called "The corporation line," that depopulates our farms, crowds our cities, and saps our country's strength!. Let the only perceptible difference between city and country homes and people be that of distance, not of kind or quality.

Send out along these auto roads city people country-bound to discard inconsistencies of dress, undue restraint of manner, unashamed ignorance of common things, to learn something of the joy of out of doors, of the beauties and blessings of country living, and the work and worthiness of its people. Then "Edythe's" wigwam headgear and "Chawley's" pancake caput cover might disappear, and both young people refrain from telling their cousin Alfalfa Apple-seed what they know of the milk weed as a dairy by-product.

Send out along these roads more and more, the country people to learn, as have our Western farmers, that the automobile annihilates distance; that neighbor, theater, church, and school are now ten or twenty minutes away, as they say in Boston, instead of as many miles, and lo! country life is changed in the twinkling of an eye or the tooting of a horn from loneliness to companionship, from unlikeness to likeness in all material things, from a slavish grind to inspiring effort.

Even the farmer's wife who remains at home may from her kitchen window catch a glimpse of a new spring bonnet dashing past which may be the inspiration of her own Easter headgear; although the creation's artistic shape may be molded from clothes basket or milk crock, she smiles more sweetly on John when he comes in to supper.

Send out along these roads a tallyho load of college boys, waving their gorgeous pennants and emitting barbaric yells. They might scare the calves and colts to death, but they would bring trailing back to the college door many a farmer boy.

Break down the barrier between city and country life. No merchant should be patronized who keeps a special line of goods for the "country trade." No milliner should prosper who offers differentiating impossible hats to country girls. A clothing store should be closed by the police that wilfully and maliciously sells a country boy a coat that marks him as "Rural Route No. 3," ten miles out, as plainly as if 'twas chalked on the back of him. "Don't take the boy off the farm" has been the plea for a decade. There is only one answer to that: "Take the farm off the boy." These auto roads will do it, are already doing it in our State of Kansas, U. S. A.

When all our careless chauffeurs are deported; when all our gumbo roads are Roman highways; when all jayhawkers go a-motoring, a-marketing, a-journeying to and fro—then shall our modern prairie schooners, 1910 model, shorn of prejudicial opposition out here in this land of freedom, of business, of roads, and of distances come into its heritage of universal use.

These things are but visions of a wakeful slumber, do you say? Maybe so, but you get the time extended on your Western Homeseekers' limited life ticket, and wait and see.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers. Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 21-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 19-26......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show. D. H. Lewis, Manager.

FOREIGN

Nov. 12-20.......London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

AMERICAN

Races, Hill Climbs, Etc.

Nov. 6-8.........Phoenix, Arizona, Road Race, Maricopa Automobile Club.

Nov. 8-9.........Savannah, Ga., Georgia Highway Reliability Contest to Atlanta, Savannah Automobile Club.

Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.

Nov. 14-17.......San Antonio, Tex., Four-Day Track Meet, San Antonio Automobile Club.

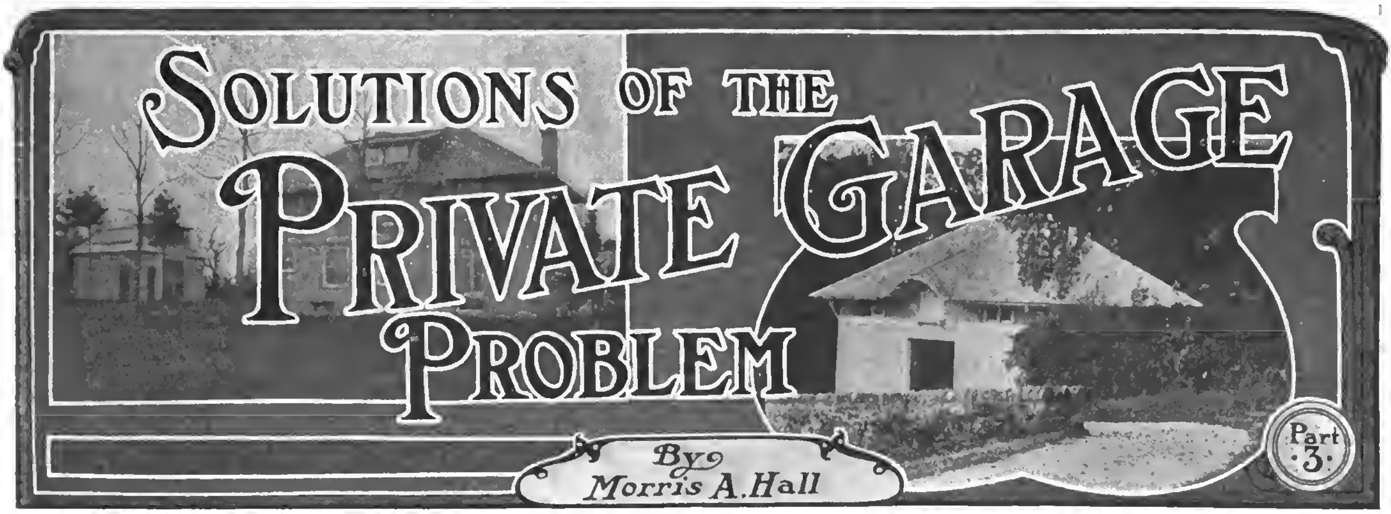
Nov. 19-25.......Redlands, Cal., Hill Climb, Mile High Hill Climb Association.

Nov. 20-21.......New Orleans, Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary.

Nov. 22..........Denver, Col., Start of "Flag to Flag" Reliability Run. G. A. Wahlgreen, Manager.

Dec. 29-30.......Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6.........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.



Small Concrete Garage Correctly Located and Well-Designed Neat-Looking Frame Structure

PRINCIPAL among the reasons why the personality of the owner should affect the size of the garage building, especially the private garage, is that one man can work in very small compass, while another must have a great deal of room. This was exemplified by a case which came to the notice of the writer some time ago. Two men shared a small frame garage, each having a car. The building was rather small, its dimensions having been dictated by economy as one could reason out from the fact of two men using one garage. Small as it was, there was room for both cars, each on its own side, and with about two feet all around. This sounds like a whole lot of room to work in, and was sufficient for one of the men. But for the other, it was not half enough, so that when he had to do any repairing of a fair day, he always did it outside, while on bad days he pushed his neighbor's car out and did his work. using that side of the garage for elbow room.

This explains how and why the personality enters into the matter of size, while the influence of size on the economy has been discussed previously. Summing up, then, the prospective builder arrives at the three sizes of his car, and adding to that the clearance dimension, as determined, has settled upon the inside size of the garage which he is to build.

It is important that the outfitting of the building with work benches, drawers, cabinets, and the like be planned out beforehand, since the size of all these things enters into the ultimate garage size. Thus, it would be more than foolish to figure on a three-foot clearance on each side, and then put a three-foot wide bench on each side, as that would take up all of the room, so that no work could be done inside.

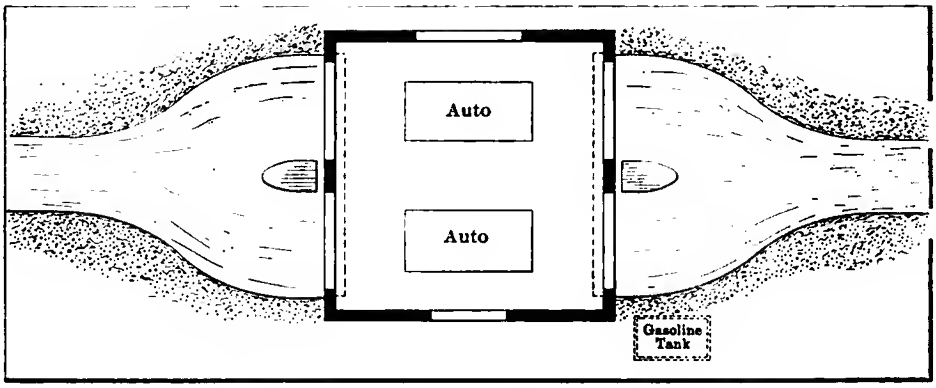
As the table published last week showed, the over-all length of cars varied from 12 ft. 6 in. for a 16-horsepower car up to 14 ft. 8 in. for a 50-horsepower car, or, in round figures, from 12 to 15 feet. The width, on the other hand, varied little, 5 ft. 2 in. being the minimum and 6 ft. the maximum. Then, if the latter figure be taken, one will be perfectly safe.

Size for a Single Small Car—Now, if the car be small, and the house be figured very close for just one car, it would seem as if not less than two feet would do for a working space, all around the car. These figures added to the smallest size give 8 ft. by 14 ft. 6 in. In addition, no one would think of building without a work bench, the least reasonable width being 2 ft. Moreover, hardly any one would think of building a special building without figuring on some sort of a locker for clothes, or parts of the car not in use. If a width of 2 ft. 6 in. be left along the back for this purpose, the whole inside size becomes 10 ft. by 17 ft.

Things done always carry more conviction than mere plans, hypothetical, or possible schemes, so it will be advantageous to consider a few more private garages which have been built with economy the paramount idea, and of a size which approximates the one just settled upon as about right for a single small car. To take these up before starting on the subject of plans for building as well as building materials, and the method of handling them, then, will be both logical and of more interest than would the reverse process.

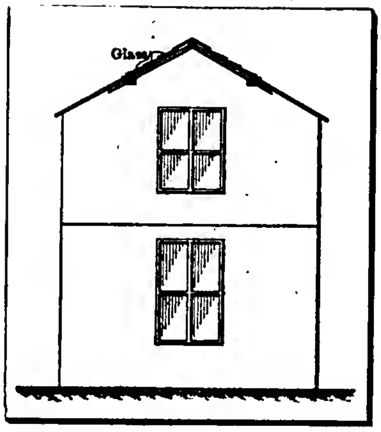
All three of the houses to be described were of wood; first, because it presented the least difficulty in construction, and, second, because it was the cheapest. The sizes vary somewhat, according to the various personalities. Thus, an eastern man built himself a garage of wood, measuring 16 by 24. Considering that he could use all of this space for himself and the car, the structure was made a story and a half high, the upper half story being utilized as a general storehouse.

Cement was used for the light foundation walls, as well as for the floor, to be described later. The building was regularly framed of dressed hemlock, and the sills, of 4 in. by 4 in. size, were bolted to the cement foundations. The outside of the frame was sided with a good grade of pine siding, regular cornice, window, and door frames being used. No sheeting was used, either inside or outside. To reduce the danger of the floor buckling, it was laid in squares, one at a time, like a sidewalk.



Plan of a Suggested Arrangement for Two Cars

Intelligent Placing Saved Maneuvering Space—By locating the house some 15 feet back from the driveway, and at right angles to it, so that the car could be driven in on a single turn and out in the same way but opposite direction, the owner saved building extra maneu-



End View of Garage Shown on Previous Page

vering space, as well as dispensing with the expense of a turntable, used by many where space is at a premium.

Doors were double and placed at the front end. The sides were lighted by means of two double-sash windows on one side, and a window and a door on the other. The loft had a window at each end. As to the utilization of the corners to the best advantage, the owner showed equally good head work. The two corners behind the doors were filled up by the stove and a big cupboard, respectively, while one of the back corners was occupied by the stairs up to the loft.

Clear across the back end ran the work bench, on which were placed both a wood vise and a machinist's vise. The anvil was located on a low bench about 1 ft. by 4 ft., and was portable, being moved around as needed. A hand drill press was attached to one of the side wall posts, as was also a corundum grinding wheel. Overhead, a light carrier track allowed of the removal of parts of heavy weight from the car to the work bench, without much manual labor, while suitable shelves and racks were set in all over the building, in various convenient places.

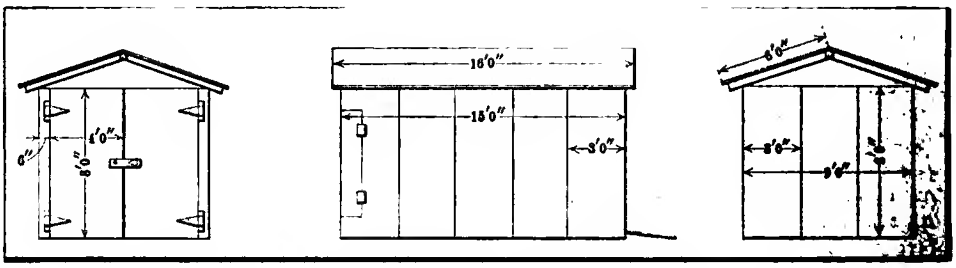
Placed in the center of the floor was the pit, over which the car stood normally. In case of using the garage for two cars, the dimensions being large enough to allow this, the pit was simply covered over with loose boards, a rather heavier one being selected to come directly under the one pair of wheels on each of the cars.

Gasoline was stored outside of the building, while the car was washed on the drive outside. No attempt was made to keep water from freezing in winter, as the owner did not use the car then, and the water from the jackets was drained off. The whole cost of this building, as described, but without any of the equipment, was just $200. This, however, was nearly three years ago.

Cost Depends Pretty Much on Owner's Constructive Ability—The above was one of the cases in which the owner did very little work himself. To take up another instance, we have the case of a man who built his own house complete, thus saving much money, and, as in a previous case, gaining much exercise and recreation from the process. Like several which have preceded, this man was a doctor.

The garage was built on the rear end of a city lot, and consequently was somewhat restricted as to size. The dimensions finally adopted were 13 ft. deep by 18 ft. wide, the latter being limited at that figure by the width of the lot. Since the floor space was not great, the owner built it two stories high, giving plenty of storage space. It was, as shown in the two figures, of frame construction, but set on a brick foundation. The walls were weather-boarded, and the roof covered with tin. In this there were two skylights, one on each side, while the floor was made of cement.

While the plan view shows a square house, the one as built, of course, was not square, this plan representing the owner's idea of his second house. The end doors are two in number



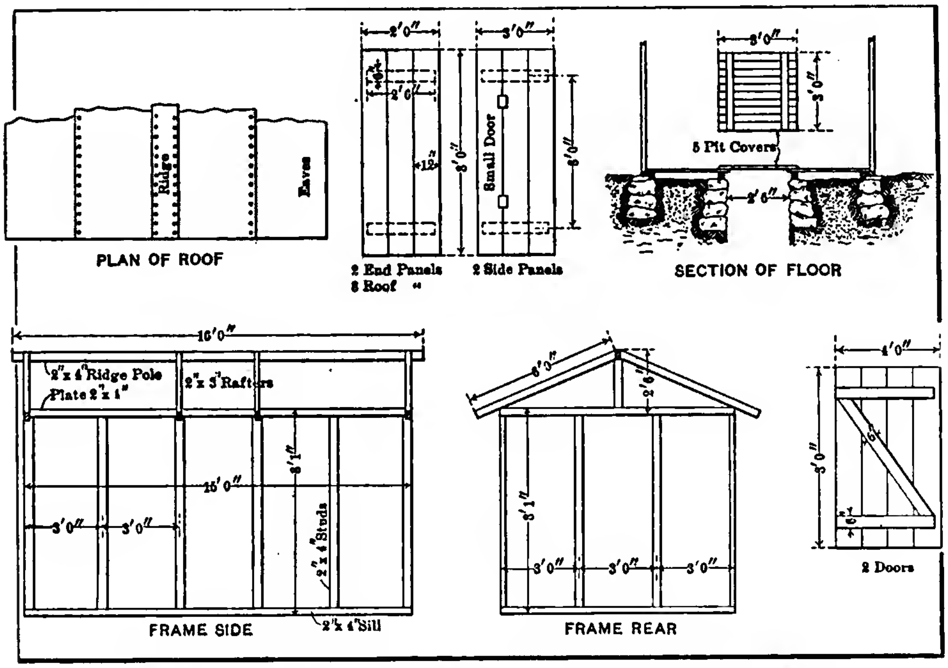
Three Elevations of Very Low-Priced Frame Garage of More Than Ordinary Merit

to allow of the individual entrance and exit of two cars, while the rear doors are the same, the arrangement being such that the cars came in at one end and went on through, out at the other.

In looking at the skylights something peculiar will be noticed about them. They are not regular, being glass laid flat on z-shaped galvanized iron members, without putty. This was an experiment, which has proved to be all right, keeping out rain perfectly. The whole cost to the owner was $100, but could not be duplicated for that, as he did every bit of the work himself, being a practical though not a practising builder.

Smallest Building at the Least Cost—What has been said before on the subject of economy has but led the way for the description of the smallest building yet described, which was built at the lowest price it has been the writer's fortune to come across. The actual size was but 9 ft. by 15 ft. outside, so that the available inside space was less than 8 ft. 6 in. by 14 ft. 6 in. While small, the owner has plenty of room, so he says, to do all necessary work upon the car.

Wood is the material of which it was made, this being built up on the panel system, for the reason that the owner did not own the house, but rented; therefore had to figure on moving the garage at some future time. The frame work, as the small constructional drawing shows, was of 2 by 4, set on sills of the same size, and surmounted by rafters 2 by 3, supporting a 2 by 4 ridge pole. Two sizes of panels were con-



Some of the Structural Details of Very Low-Priced Frame Garage

structed, one 3 ft. by 8 ft. and the other 3 ft. by 15 ft. The latter were used for the floor, two being used, one on each side of the pit. The former being used for the walls and roof, six for each side were necessary, three for the closed end, eight for the roof, two for the door, and the two for the floor, making twenty-one.

Two feet six is the width of the pit, and to cover it when not in use five panels, each 3 by 3 ft., were made with beveled ends. All material was bought at wholesale prices, being cheap Norway or Mississippi pine or hemlock. This is preferably dressed on one side to receive the paint or tar paper. The quantity of material used was as follows, this including everything:

One-Inch Lumber Required.

Twenty-one panels 8x3 feet.	Two gables 9x2 feet.
Two doors 8x4 feet.	Two door frames 6 inches by 8 feet.
Four-inch batten 140 feet.	Factory floor 150 square feet.
Two collar beams 6-in. by 8 ft.	

Hardware Required.

Two press T hinges.	Three hooks and eyes.
Two press 2x2-inch steel butts.	One clasp and staple.
One gross 2-in. No. 10 screws.	Twenty pounds wire nails.

Two by Four-Inch Timber Required.

One ridge pole 16 feet.	Two sills 14 feet 8 inches.
Two plates 9 feet.	Two sills 9 feet.
Two plates 14 feet 8 inches.	Four floor beams 14 feet 8 inches.
Four corner posts 7 ft. 9 in.	
Ten studs 7 feet 9 inches.	Eight rafters 2x3 inches, 6 feet.

Two squares Ruberoid roofing.

Made-Over Barns Are Convenient, But Show Their Ancestry

As will be noted from the above, the roof was covered with a patent paper, ruberoid, of which two rolls just made the roof. To put the whole together, the owner hired an intelligent laborer, superintending the work himself. The time consumed in this was five days. The whole cost of the house finished was $35, this including lumber, hardware, labor, but not paint, nor the tools which it was necessary to buy in order to have the laborer do the work, namely, a carpenter's level, a saw, hammer, and screwdriver. All panels were put together with nails, while they were fastened to the frame with screws.

Remarkably Low Cost Puts Private Building Within Reach of All—Figures of this sort, accompanied by drawings of the building as actually built, show that the private garage or motor house for every car, or for every owner, is within the range of possibilities, for it seems highly improbable that anyone could buy an automobile and run it, who would not be able to afford at least $50 for this purpose. Consulting the figures given above, this is seen to be enough above the actual cost as to allow a comfortable margin for tools, paint and a few additional small parts. The sum of $100, on the other hand, allows a very wide latitude in the finish of a house like this, enough perhaps to permit plastering on the inside or sheeting on the outside, to make it more warm in winter.

Many owners, however, look at the frame house as dangerous, as it is impossible to keep a car in a garage and not have gasoline in there also at all times. This keeps the danger of fire

Interior of Portable Frame Garage Showing Arrangement

always present. With any kind of a frame construction, this ever-present danger is so objectionable that many people will go without their own garage until they can afford one of stone, concrete or other strictly fireproof construction.

Of course, all that has been said on the subject of economy both relative to size and material, as well as to economy of construction in time and money, will not interest very much those well supplied with both. For this class, then, it will be necessary to take up the more ornate and sumptuous garage, properly designed and carefully constructed.

Between the two there is the extensive middle class, desiring a modest, yet ample structure, not entirely ugly, but not wholly given over to artistic effect. For this class, and this is the class owning the largest number of automobiles of to-day, and the largest prospective class of to-morrow, the garage must possess then a reasonable amount of appearance, a maximum of utility, and with the cost a secondary consideration.

For this class it will be well to give some few examples of larger sized garages, which should, however, be of equal interest to the little fellow, since from an inspection of the details of the more commodious places, he may glean many useful ideas to be worked out in his own garage in a less expensive manner.

(To be continued)

KICKS ON "LETTERS"

Editor THE AUTOMOBILE:

[2,073]—I have been reading your magazine for a number of years past and have tried to glean some information from the various answers you print to "Letters Answered and Discussed," as I think this feature could be made a most valuable one. I wish to be put on record in saying that you, and not only you but other magazines, fall short of just accomplishing the ideal. What excuse have you for publishing two pages of answers as your edition of October 21 did, with every name or information as to the make of car discussed eliminated or designated by "a well known make"? This elimination at once destroys the "public" interest in your letters which could be of incalculable value. Why not answer each letter personally, for, without the car's make known, how can it be of interest to owners and drivers? I could point specifically to the first two letters (2,059 and 2,060) that you have used two columns in answering.

As an old newspaper man, I can guess at your reasons for this elimination, but I don't think it "pays" in the end. Manufacturers are not hiding nowadays behind poor material or poor workmanship, and I think are not afraid of such publicity. Most of the "troubles" complained of, anyhow, are caused by want of experience and not by mechanical or material deficiencies. If you can do so, I hope you will include this letter in your above-mentioned department, and let us see if others do not feel as I do about the matter, which I hope I have not handled too roughly. JOHN W. FEW, JR.

Middletown, Pa.

If, as you say, most of the troubles complained of are caused by want of experience, and not mechanical deficiencies, it would seem as if there was nothing to be gained by giving the car name. If a man has starting trouble, for instance, what he wants to know is how to start that engine, why it won't start, and how to change or correct it so that it will start. He does not care a continental what make of car Bill Jones drives, but if Bill had starting trouble and fixed it readily, he will be interested to know what was done and how, so as to apply it to his own specific case.

Anyway, you are accusing us of something of which we are only partly to blame. As a matter of fact, few of those who ask for information under the heading of "Letters" give us the name of their car. For instance, in the issue you refer to, that of October 21, there are six letters. Of these we only had the car name of two, one-third of the total. Then, to turn back another week, in the issue of October 14, there were thirteen letters, all without car names. Of the thirteen, we had the name of just one car, one-thirteenth of the total number.

To go back to still another issue, in the October 7th issue, there were nine letters. Of these we had the car name in but one case, and that was accidentally given. More than that, we believe in all of the other cases, unless possibly the two you specifically mentioned, that the car name would be superfluous. This may be instanced thus: what good would the car name be in an inquiry for brass finish, ball-bearing applications, shipping a car to 'Frisco, making rubber cement, etc., as per the letters in October 7 issue?

In all of the letters handled for this (November 4) issue, but one gives the maker's name, and except in so far as it enables us to look up details in that maker's catalogue, which the troubled one forgot to give us, that is of no particular bearing. In short, if, like all of the others, he had forgotten to give the car name, we would have been able to answer the question just as well, and it would have been of just as much general use as it is in the shape given. Unfortunately this letter did not find its way into this issue.

ANOTHER STARTING CRANK

Editor THE AUTOMOBILE:

[2,074]—In letter 2,047 of your Oct. 14 issue was asked a question, which I hoped would be answered more fully, as I have had the same difficulty in starting engines, and in particular with a four-cylinder air-cooled engine. Precisely as this letter indicates, the engine is hard to start, but when by some accident it starts after being thoroughly cranked, then it will start on the spark nearly every time, or at any rate, at the first turn of the crank. On the other hand, when it has run an hour or so, or if it stops, it is as hard to start as at first. I cannot believe that it is in the wiring, as indicated in your reply; in fact, I am sure that is not the case with my machine, as I have had my wiring renewed once and examined a number of times, without in the least changing the result.

Vermillion, S. D. W. H. BEEDE.

In the issue following the one you mention will be found another letter on the subject of hard starting. In that case, as you will see by reading the letter in question (2,059) and our answer to the same, you will note that the suggestion is made that too much air has been used in trying to start, as the cold engine ad cold air will not vaporize much of any fuel. By putting in a large proportion of gasoline relative to the amount of air used, the engine and air, cold as they are, are still able to vaporize enough of the fuel to start. After starting, the heated cylinders, pipes and other parts help very materially in vaporization, and the second start is easily made, even, as you suggest, on the spark a number of times.

As for a recurrence of the trouble after the machine is thoroughly warmed up, that we cannot understand; in fact, from your description of the trouble we are unable to distinguish between the first case, when "she" starts on the spark, and the second, in which the motor will not start at all.

It is just possible that some of your trouble may be due to the exhaust valve being timed wrong, although on the basis of regular running (we assume this because you say nothing to the contrary) this would seem to be rather far-fetched.

If the machine is mechanically right in every respect, the trouble must be one of two things, poor or incorrect mixture, or poor or defective ignition. We suggested the latter in our answer to letter 2,047 because he stated that the fuel system appeared to be right.

TWO CYLINDERS BALK

Editor THE AUTOMOBILE:

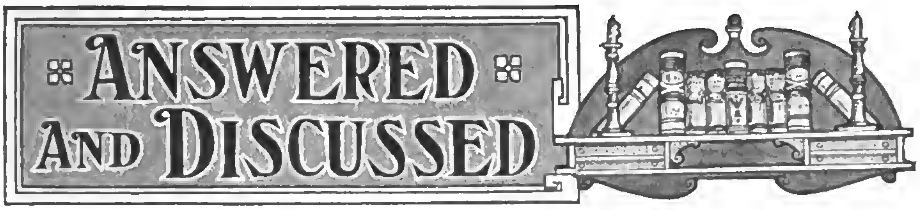
[2,075]—Will you please help me out in a peculiarly troublesome case of missing? I am using a Remy magneto on my four-cylinder car, also, five dry batteries to start the motor. When I test the dry batteries by detaching the cable from the spark plugs, trying one at a time with the engine running, I get a ½-inch spark from cable end to plug with characteristic crackling noise from each of the four. When I switch to the magneto and test in the same manner (other conditions exactly the same) I get a ½-inch crackling spark at the two outside cylinders, but little or none from the two inside cylinders. When on the road and things get warmed up a little, conditions are better, but still it is liable to happen at any and all times. What is the real trouble? Is there any A B C treatise on the magneto? GEORGE H. JEROME.

York, Neb.

If your magneto is of the old kind and worked through the coil on the dashboard, the trouble might lie in the coil, at least as you describe it. that is the first inference. On the other hand, if you have one of the newer self-contained coils of the inductor type, which do not use a separate coil, the trouble must be in the distributor. This is inside of the magneto at the front end, and may be reached by removing the hard rubber cover.

To be more specific, one of the contacts, or, rather, two of them, may be worn in an unusual manner, due to an unexpected flaw in the metal or something of that sort. These unusual flaws, or whatever they are, cause a poor contact at those points, so that the two cylinders connected up to them do not receive a full spark, due in turn to the impaired circuit.

Very few magneto books have been published dealing with that piece of mechanism exclusively. One of those is "The Magneto, Its Construction and Operation," by S. R. Bottone. Then, a number of books of a more general character treat of the magneto in some specific chapter on ignition. Some of these are well worth having. Among them are: "The Gas Engine," by F. R. Jones; and what will probably fill the bill best of all: "Automobile Catechism," in which are a series of questions and answers, all taking up the simplest parts of the automobile. In this latter you will find 20 pages on Ignition, 22 on Operation, and 17 on Troubles and Remedies, all of which contain much that will be useful to you. In the larger book, Chapter 3 contains 52 pages on Ignition, of which 12 pages deal specifically with magnetos and generators. Also, in Chapter 4, on Control, consisting of 47 pages, much of which deals with ignition troubles and remedies, you will find a great deal that will interest. All of these books may be obtained from the Class Journal Publishing Company, 231 West Thirty-ninth street, New York City.



GEAR BOX PLACING

Editor THE AUTOMOBILE:

[2,076]—Please advise me through "Letters" if the location of the sliding gear transmission on the rear axle gives satisfactory service, and is durable? Also, what about bearings, are plain the best, or roller, or are balls superior to the others?

Gordon, Neb. LOYD H. JORDAN.

To the best of our knowledge, the rear axle location for the transmission, whatever its type, is satisfactory. One might argue back to this conclusion from the fact that one of the oldest manufacturers, making the highest grade of car, adopted this location for the gear box in 1904, and is still using it. More than this, at the time it was adopted there were no others on this side of the ocean using this placing. To-day, after five years of use, this company still thinks as well of it as when first adopted. In the meantime the copyists of this location number scores, and the cars so outfitted run into the thousands.

No one can state absolutely that this or that form of bearing is best. Each one has some advantage of cost, wearing quality, lubrication, or lack of the same, adaptation to special designs, or others to fit it for some particular case. Each one of the three mentioned is in wide use on automobiles.

SOME STARTING QUESTIONS

Editor THE AUTOMOBILE:

[2,077.]—Will you kindly inform me as to the following through your excellent department of "Letters Interesting, Answered and discussed":

1. Are there any manufacturers who make at present a cranking handle which will prevent the severe blow given to the arm when a back fire occurs, due to cranking with the spark lever set in advanced position?

2. I have invented a cranking handle device, which will positively prevent any injury to persone cranking, no matter what may be the position of the spark lever. Will you kindly inform me if there is any market for such a device, and give your opinion of the extent of such a market?

3. Would it pay to take out a patent for such a device, and interest capital in the same, or do you think the average automobilist would say that he needs no such device, as he never forgets to set his lever back when he begins to crank?

4. Would the automobile manufacturers be inclined to put such a device on their machines as a regular equipment?

HENRY I. LURYE.
West New Brighton, Staten Island, N. Y.

Now, as at all times, the question of a proper and safe starting device is engaging the attention of both manufacturer and user. However, the maker of large and expensive cars wishes a starting device which may be operated without physical exertion from the seat. The maker of low priced cars, on the other hand, does not want anything very expensive, although a device such as you speak of should do very nicely, as it would give the manufacturer a strong talking point. This is a matter which has been discussed in these columns on several occasions.

As to your first question, there was a cranking device not radically different from the one spoken of, which was described in a recent issue of THE AUTOMOBILE, Sept. 23, 1909, to be exact. Aside from that, we know of nothing which answers this description.

Comment above should answer the second question, while as to the third, if you intend to make and sell these cranks, it would certainly be to your advantage to take out a patent, whereas, if you intend to sell out, it would be better to let the other party take out the patent, or else take it out yourself and sell for enough additional to more than cover the cost. This we spoke of in a recent issue, giving the Government fees as $35, with patent attorney's fees extra.

Once more, we would refer to the comments above as answering the fourth question, also.

DETAILS OF 1910 MODELS

Editor THE AUTOMOBILE:

[2,078]—Have you at hand or will you have any publication giving a complete list of the 1910 automobiles of American make, including detailed descriptions, price, and illustrations of each?

Northwood, N. D. H. H.

It is a little bit early for the publication of details of next year's models, but in this week's issue, elsewhere in the paper, you will find the first table of 1910 cars, this table being restricted to those cars which will be exhibited at the Atlanta show.

Later on, at the time of the two big New York shows, the descriptions and details of all of the cars will be given, just as was done last year. There is no publication that we know of which would give you this as soon. Both the A. L. A. M. and the A. M. C. M. A. publish handbooks, but these are not issued until long after the shows mentioned. More than this, these books do not include any non-members, so are not as complete, taken together, as are the tables printed in THE AUTOMOBILE.

TELLS HOW TO START

Editor THE AUTOMOBILE:

[2,079]—I have read with the greatest interest and benefit, for the past four years, "Letters Interesting and Instructive"; therefore let me contribute my mite for the relief of No. 2,059 and many another autoist who is not fool enough to lay up his car with the first frost. It is axiomatic that all cars start hard in cold weather, due solely to the low volatility of the fuel. The tyro gets busy with the nozzle adjustment and tries to correct by increased richness of mixture. This is wrong except very slightly in the coldest weather. Now, here is the remedy for balky motors on cold mornings or any old time. Provide a priming mixture of 50 % sulphuric ether in gasoline (equal parts mixture). In starting, first prime the carburetor in the usual manner, then moisten a silver dollar-sized spot on a piece of cloth and lay over the intake of the carbureter, open throttle well and "she" will go every time; or prime through the priming cocks in the usual manner. Explanation—ether is four times as volatile (and correspondingly explosive) as gasoline.

DR. CHARLES H. MILLER.
Chicago.

The attention of our readers is particularly called to the last sentence, in which it is stated that sulphuric ether is four times as explosive as gasoline. This should be borne in mind by all those using this scheme to start the car quickly on cold mornings.

Readers who do not possess a silver dollar might try this scheme using a smaller coin, such as a half-dollar.

COST OF GLYCERINE

Editor THE AUTOMOBILE:

[2,080]—Will you please give me the address of a first-class wholesale drug house from whom I can get glycerine for use in automobile water-cooling systems, to prevent freezing up in winter. I would be greatly pleased if you would also find out for me the price of this in quantities.

Greenville, S. C. E. F. BATES.

This inquiry was referred to Hegeman & Company, 200 Broadway, New York City, who kindly supplied the following: Glycerine is put up for quantity orders in two forms, one a 50-pound can and the other a 550-pound drum. The former costs 20 1-2 cents per pound, f. o. b. N. Y., the can being free. This makes the cost of that sized can $10.25 plus the freight charges. By taking the larger-sized drum the cost per pound is less, being only 18 cents, but a deposit of $9.00 is required on the drum. This deposit is returned upon the return of the drum. This form would tie up $99 plus the $9 deposit plus the freight charges on the full drum going and the empty drum returning. It should be borne in mind that both of these figures refer to No. 2 quality, which is suitable for the purpose mentioned, but not for all purposes where glycerine is used; being, in fact, a rather impure form, suitable for mixing with water to prevent freezing.

SUGGESTS GLIDDEN ROUTE

Editor THE AUTOMOBILE:

[2,081]—Please put the following suggestions for the 1910 Glidden tour route in "The Automobile": Start at Chicago, go to Indianapolis, French Lick Springs, the Carlsbad of America, Louisville, Abbey of Gethsemane, Lincoln Memorial Farm, which will be visited by President Taft and possibly again by ex-President Roosevelt, Mammoth Cave, which is the mecca of thousands of tourists every year, Nashville, Chattanooga, Chickamauga, National Park, Atlanta, then to New York City via the National Highway. The United States is honoring Lincoln's memory by having two presidents visit the farm, is it not fitting, and I might say, patriotic, for the A. A. A. to join in honoring the great war President's memory by having the Glidden tour pass through this section? What do you think of this route?

CLAUDE W. WILSON.
Bardstown, Ky.

There must be many others who have in mind some road or route which would be advantageous for tourists to follow this year. Such persons are invited to send it in.

NOVEL THERMO-ELECTRIC POWER INDICATOR

POWER readings of gasoline engines have hitherto been obtainable only in laboratories, at no small expense; and private owners of automobiles and motor-boats have always longed for some convenient instrument which would reliably indicate the performance of their engines. The Hopkins gasoline engine dynamometer, the invention of N. Monroe Hopkins, Ph. D., furnishes such indications, either for the complete engine or for any individual cylinder. By its use the driver can immediately determine whether his engine is developing its full power, and if it does not do so, can find which cylinder or cylinders are at fault. For determining the best carbureter adjustment, or locating troubles in the ignition circuits, the Hopkins dynamometer should prove invaluable.

The principle of the device is very simple. It has long been known that an electric current is generated by the heating of the junction of two strips of dissimilar metals, and that the magnitude of the current so generated is proportional to the temperature at the junction. The famous scientist Becquerel first suggested the use of this principle in constructing a thermometer, and such thermometers are used to-day in all places where extremely high temperatures must be measured.

Power Indicated by Thermometer—Professor Hopkins saw the possibilities of this thermometer in gasoline engine use. The gasoline engine is distinctively a heat engine. The temperature of the combustion of the mixture in its cylinders is proportional to the pressure, and consequently to the power developed. A Becquerel thermo-electric thermometer fitted in the cylinder will give an index to the performance of the cylinder. If the cylinder fails to fire, its temperature will fall off and change the reading, giving immediate indication of trouble.

The application is as simple as the principle. The two wires of suitable (different) metals are imbedded in porcelain, to insulate the electric current generated and protect them from the violence of the combustion in the cylinder, and are carried in a plug similar to a spark plug. The ends of the wires are connected to an electrical indicator, which shows the amount of the current. By a suitable switch, the indicator can be connected to any one cylinder, or to all in series. Much experimentation was necessary to develop the plugs and indicator to the point where they would withstand the high temperatures and hard usage incidental to gasoline engine work.

As the instruments must be used on widely varying engines, it is not practicable to calibrate directly in horsepower; instead, the scale is calibrated from one to 100, which may be read as per cent. of the maximum power. If the maximum power of the given engine is known, and the instrument is adjusted to read 100 when this power is being developed, then the power developed under any other conditions can be readily determined.

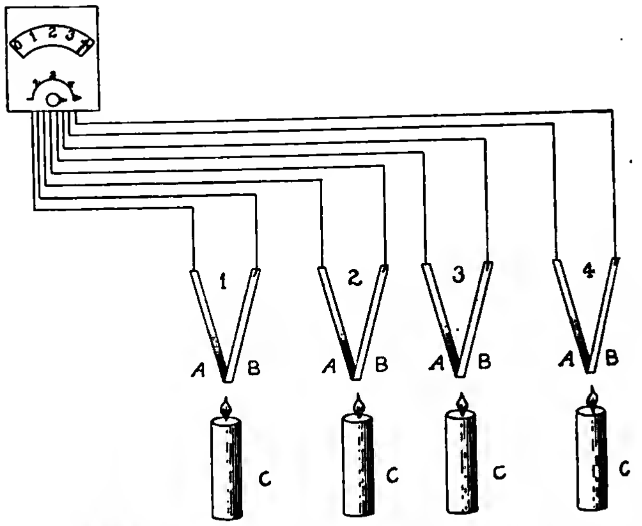


Diagram of Hopkins Thermo-Electric Indicators

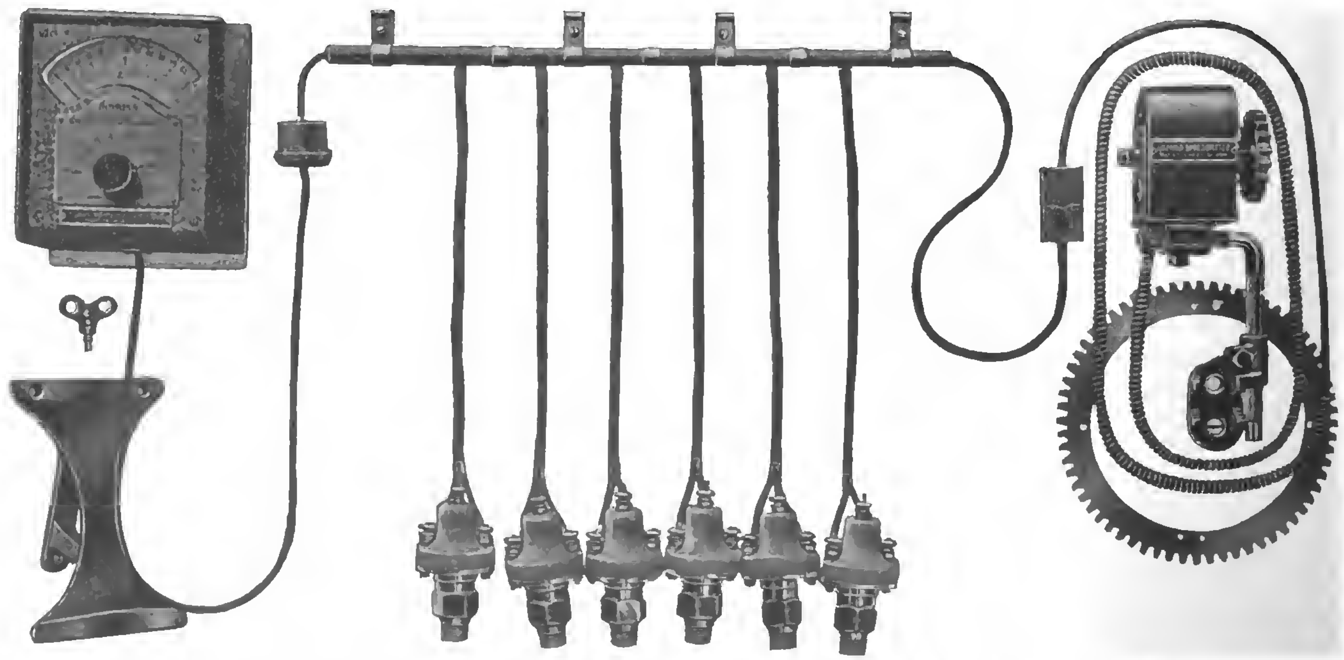
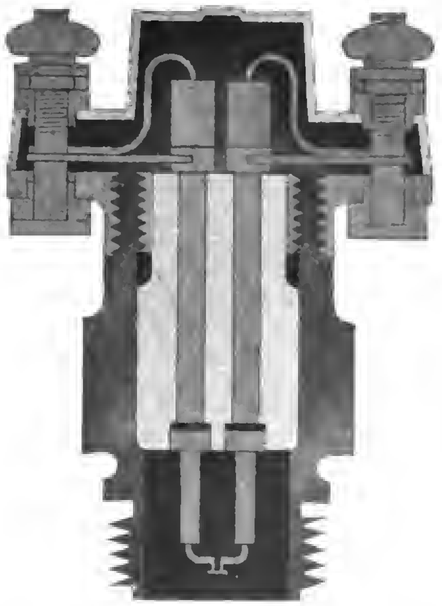
A and B indicate the pairs of dissimilar metals; C the sources of heat. All four indicators are connected in series, giving their combined reading on the scale.

Application to Autos and Boats—In its commercial form, as developed for the market, the dynamometer is combined with a speedometer. The latter consists of a very small magneto, enclosed in a water and dust-proof case, which is carried on the steering knuckle and geared to the front wheel. The current generated by this magneto is in proportion to the speed at which it turns, and this current may be read on the same indicator used for the dynamometer. The switch which connects up one or all cylinders has an additional position which connects with the magneto-speedometer. This instrument accordingly has two



Hopkins Indicator Complete: Plugs for Six Cylinders, Indicator Proper, with Bracket, and Electric Speedometer



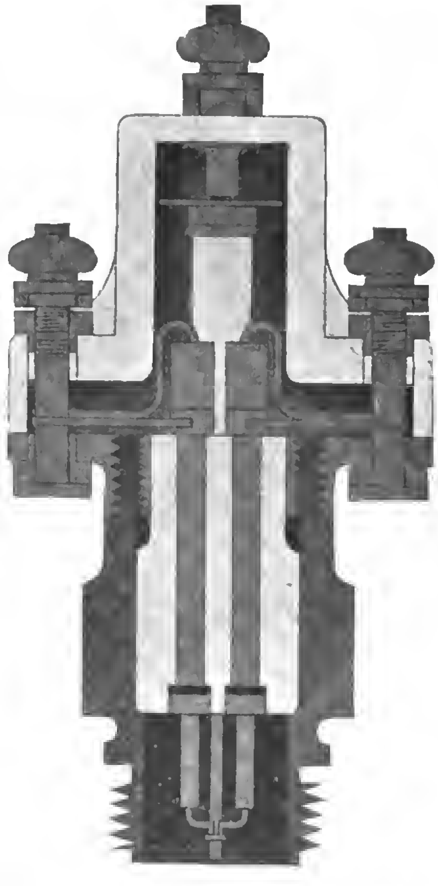
Cross-Section of Hopkins Plug

scales, one graduated in per cent. of total power, and the other in miles per hour or revolutions per minute, if for motorboat use.

The thermo-electric plugs—the little thermometers, as it were—are usually made in combination with the spark-plugs. That is, the plugs furnished with the instrument can be screwed into the cylinders instead of spark plugs, being connected to the ignition circuit on one side and to the indicator on the other. For use on engines with make-and-break ignition, or when desired from other reasons, the indicating plugs can be made separate. In this case they can be set into the cylinders through holes drilled in the valve caps.

Testing Individual Cylinders—It will be found for nearly every engine in good condition that the dynamometer indication for the maximum amount of work from a single cylinder will be about 10 on the scale—the lower of the two scales shown in the photograph of the instrument. This figure 10 for a single cylinder should be read as 100 per cent.; each single division from 1 to 10 on the scale should then be read as 10 per cent.—that is, 10 per cent. of the maximum work of which the cylinder is capable. When the engine is first started and running idle, each cylinder may show about one (10 per cent.). A well-designed gasoline engine should have its individual cylinders match up almost perfectly on the scale. If any cylinder lags behind, it is certain that that cylinder is not doing its share of the work.

Overheating of the engine, it might be supposed, would cause the plugs to give a higher reading than when the engine is running at normal temperature; but such is not the case. The plugs are insulated from the cylinder walls by thick porcelain bushings, which act as non-conductors of heat. The temperature of the cylinder walls has practically no effect whatever on the plugs; they show only variations in the temperature of the burning gases in the cylinder. The Hopkins dynamometer and speedometer is now being produced commercially by the Electric Speedometer and Dynamometer Manufacturing Co., of Washington, D. C., under the trade name of the "Dynatak."



Same, Combined with Spark Plug

RESULTS OF TESTS OF CAST-IRON BARS

MUCH interest has been aroused in the subject of cast iron and its strength in connection with a more extended use of this metal for automobile parts. The common and erroneous idea is that this is a very unreliable metal, so that its name has without reason gradually come to be used as a term of reproach. That such is far from the real situation may be deduced from a series of tests just concluded by A. F. Nagle at Bethlehem, Pa., and reported in a paper to be read before the A. S. M. E. at the annual meeting in December.

The bars tested were normally 2 inches by 1 inch by 24 inch centers for transverse tests, and the tensile bars were 1 5-8 inch by 6 inches, turned to 1 1-2 inch diameter and threaded, while the middle portion was turned down to 1.129 inch in diameter to give exactly a square inch breaking section.

All told, some 217 pairs of test bars were tested, of which 42 are designated as abnormal, the ratio of tensile to transverse strength being either much above or greatly below the average.

No particular care was taken to have the iron or the pouring different from what might be considered as an average case, the bars being cast from two patterns in the same mold, this being inclined about 30 deg. The iron for the bars was poured from a small ladle of iron taken as near as possible from the middle of the pour for the main casting.

Throughout the table will be noticed the unusual regularity of the figures, the differences from the average of 217 pairs of test bars taken and tested over a period of nearly two years being represented by the two extremes of 13 per cent. low and 24 per cent. high, an unusually even and regular result.

COMPARISON OF CAST-IRON TEST BARS

Number of Specimens	Limit of Breaking Load of Transverse Bars	Breaking Loads Pounds Transverse	Breaking Loads Pounds Tensile	Deflection Inches	Ratio of Tensile to Transverse
29	2,000 to 2,200	2,065	21,630	0.43	10.47 to 1
36	2,200 to 2,400	2,289	22,940	0.45	10.02 to 1
51	2,400 to 2,600	2,523	24,880	0.47	9.86 to 1
43	2,600 to 2,800	2,756	26,500	0.49	9.61 to 1
16	2,800 to 3,000	2,894	28,460	0.49	9.83 to 1
175	Averages	2,383	23,732	0.45	9.96 to 1
		Above 10 to 1 ratio			
10	2,000 to 2,200	2,088	27,143	0.41	12.95 to 1
10	2,200 to 2,400	2,294	28,530	0.43	12.44 to 1
4	2,400 to 2,600	2,436	29,600	0.49	12.15 to 1
0	2,600 to 2,800				
1	2,800 to 3,000	2,890	34,000	0.45	11.76 to 1

Assembling Place in the Old Royal City of Versailles

PARIS, Oct. 25—Over fifty commercial automobiles are engaged in a trial which will last one month and calls for a regularity run of nearly three thousand miles. The event is the annual industrial and military vehicle trials of the Automobile Club of France, with the army as a backer. The army influence is considerable, for the government, desirous of obtaining automobiles for transport work, has instituted a bounty system. The vehicles complying with the regulations in this contest can be offered to the public with the advantage of a bounty of $600 the first year and $200 each of three following years, on condition that the owner agrees to present his automobile annually for inspection and to hand it over to the army in case of mobilization. For a nation trained to compulsory military service the conditions are not onerous, while the bounty is sufficiently high to be a valuable asset to the user of commercial automobiles. The outcome will certainly be a large increase in the number of commercial vehicles in France. The record number of entries is able proof that manufacturers appreciate the importance of the government aid.

Versailles, ten miles to the west of Paris, has been selected as the headquarters of the commercial contest. In one of the wide avenues of the old royal city an immense garage has been erected, with boxes down each side for the rows of competing vehicles, and a separate portion in which fuel is stored, the committee have their offices, and accommodation is provided for visitors and the press. Although the building is erected in the main street, and will have to be pulled down in a month, no expense has been spared to fit it for its purposes. The roof of the building has been made double, with a thick layer of sand between the two, while fire hydrants are placed at intervals of a few feet down the full length of the building.

The official garage is rigorously closed to all but members of the jury; in this case the closing is effective, not equipped with the usual French loopholes and exceptions. Whatever your claims, no admittance will be granted by the artilleryman on guard unless you can show proof that you are a judge. As each driver brings in his vehicle, he is only allowed to back it into its box, stop the engine, turn off the oil and gasoline and come away without a moment's hesitation. When the morning start is given, the driver can enter the garage only at the official hour for commencing the run, starting, filling tanks, oiling or washing being included in the running time.

Two sets of regulations are in force, one being drawn up by the Automobile Club of France, the other by the army authorities. Some of the vehicles are competing under the two, others have made a selection. The army insists on certain conditions which are not absolutely necessary for ordinary commercial purposes, but they do not as a rule prevent the standard type of commercial vehicle from taking part. The military authorities have a preference for metal wheels, though allowing solid rubber, and barring pneumatics. The driver must always be protected, the width, length, and axle load are all determined, and among the running requirements are the ability to travel in convoys with and without load, to use gasoline, alcohol and benzol.

Economy is the basis of the test. During the month's running three different kinds of fuel have to be employed. For the first thirteen days, gasoline is supplied to all the competitors, and on two of those days, the consumption is officially controlled. For the following week the vehicles must consume alcohol, with one day a consumption test; and during the last portion of the trials benzol will be obligatory, with one day for the official control of con-

Marquis de Dion, Gen. Brun, Minister of War and M. Millerand, Minister of Public Works sumption. As there will be not less than a week on each of the different fuels, the ability of the engine to work with gasoline, alcohol and benzol will be fully proved, while the official consumption test only taking place after several days previous run will give an opportunity to tune up the carbureter on the road to the efficiency it would have if specially prepared to use only one of these three fuels. Of course whatever adjustments or modifications have to be made to suit the changing fuels must be carried out during the running time. Lubricating oil, which is generally neglected in competitions of this nature will be fully taken into account on this occasion. The amount used will be controlled from the commencement to the end of the trials and included in the efficiency formula.

De Dion Truck Negotiating the Route Beyond Larcelles

The final classification will be made on a ton mile economy basis among the vehicles that have made all the controls on time during the entire month of the competition. The formula is

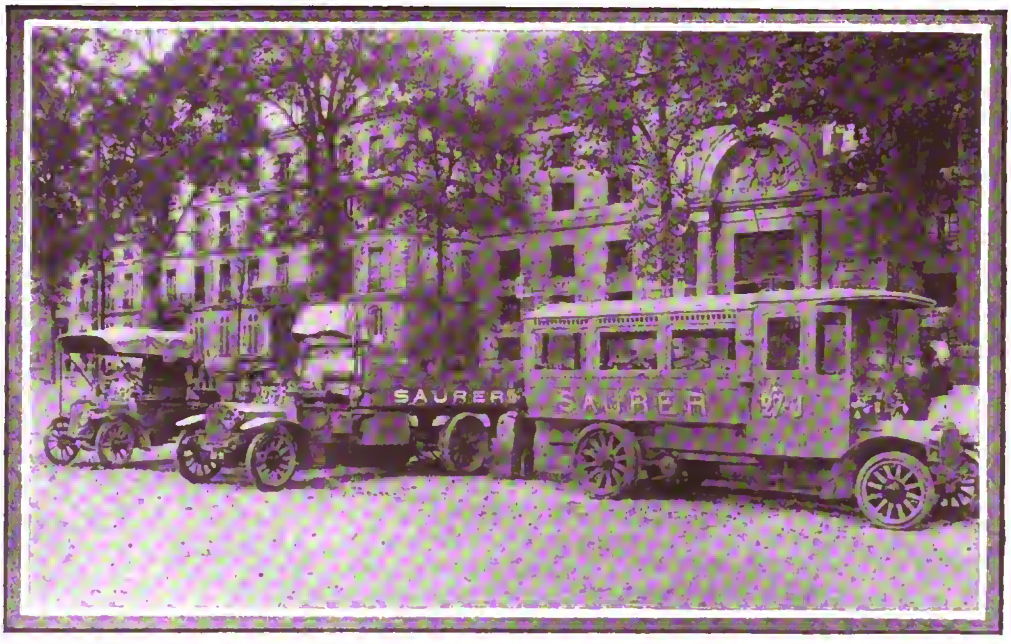
$$\frac{T}{P}\left(C + C'' + K\ P''\right)$$

in which T is the duration of the runs in minutes; C the fuel consumption per kilometer in francs; C" the consumption of lubricating oil per kilometer during the entire trials; K an estimated cost of the wear and tear of tires and wheels; P the useful load in tons, bodywork being included; P" the total weight of the vehicle in tons. No account is taken of speeds above the maximum allowed under the regulations. Thus the only advantage to be obtained from speeding would be time to make adjustments before going into the closed garage.

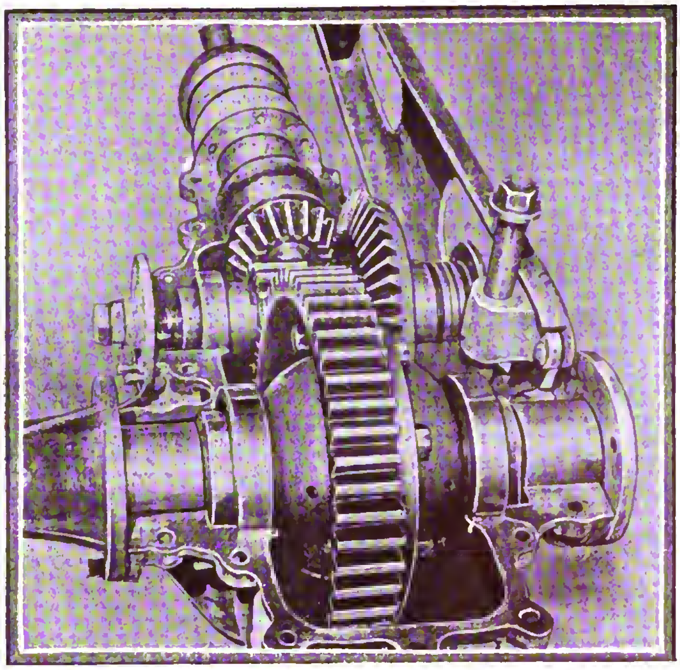
During the first days of the competition the runs were in the neigbborbood of Versailles, starting and finishing at the official garage. This was quite sufficient to test the abilities of the vehicles, for several of the hills in the neighborhood have grades of 10 to 12 per cent., with turns at tbe bottom that considerably increase the difficulty of climbing. After the first four days a run was made to Clermont-Ferrand, in the center of France, the trip being made in stages of 60 to 120 miles according to the class of vehicles. On the return, after an absence of seven days, the runs around Versailles are to be continued until November 15.

There are three distinct divisions in the competition, comprizing goods-carrying automobiles, road trains, and small omnibuses. Each of these are subdivided according to load capacity. In the smallest class, with a load capacity of 880 to 1,320 pounds, only one vehicle is entered. It is a two-cylinder Bayard-Clément identical, so far as the chassis is concerned, with the company's taxicabs in use in Paris. The bodywork is closed, suitable for such light trades as grocer, or baker. In the second class, carrying a load from 1,324 to 2,645 pounds, the entrants are De Dion-Bouton, Delaugère-Clayette and Vinot-Deguignand. All three have closed vans mounted on pneumatic tires. Delaugère-Clayette and Vinot-Deguignand use Michelin twins on the rear and singles on the front, all equipped with the latest type of Michelin dismountable rims. As a compressed air tank is carried for inflating tires, delays under this heading are not likely to occur. The outfit is such a one as would be adopted by a firm desirous of obtaining a fast delivery service with every guarantee of regularity.

It is somewhat of a surprise to find a single cylinder in a commercial vehicle class with a useful load of about one ton. It is De Dion-Bouton who have made this entry, their vehicle being one of the models used by some of the largest dry goods stores



Saurer Omnibus of Characteristic Type, and Two Trucks



Rear Axle Construction of the Vinot-Deguignand

in Paris for long distance delivery service in the suburbs of Paris noted for their steep grades. As the one lunger has satisfied its commercial users for one year under normal working conditions, there is no reason why it should not come through this severe public test with highest marks. The single cylinder is carried under a bonnet that could accommodate three other units without any difficulty whatever. It transmits through a disc clutch to a three speed sliding gear set, and has final drive, as in all De Dions, by transverse cardan shafts. There are two separate axles, a solid one carrying the load, and another one, broken by the differential, taking the drive to the rear wheels.

There is also a novel feature about the Vinot-Deguignand rear axle construction. Instead of the large bevel being on the rear axle, it is mounted on a lay shaft within the differential housing, and parallel to the rear axle. The bevel gear on the end of the propeller shaft meshes with the crown bevel on the lay shaft, while a plain gear in the center of this shaft engages with a pinion on the center of the rear axle. Incidentally this places the differential exactly in the center of the rear axle. The engine on this car is a four-cylinder type of 14-horsepower with an arrangement for sending cold air into the cylinders during runs on down grades. Only Saurer and Bayard-Clement have entered in the 2,647 to 4,400 pounds load class, the former having a four-cylinder engine in one casting with an open type of body, while the latter has a two-cylinder engine of 14-horsepower driving a stout chassis with a closed body. The vehicle is mounted on a special type of cushion tire known as the Ducasble.

In the two classes for vehicles carrying a load of 4,400 to 6,613 pounds, and those taking more than 6,613 pounds, entries are numerous, these being the types of automobile required by the army. Nearly all the leading French firms are represented, the list comprising such well known factories as Delahaye, Schneider, Aries, Panhard-Levassor, Berliet, De Dion-Bouton, and Malicet & Blin. There is a remarkable uniformity about the vehicles, although plenty of differences exist in details of construction. In every case gasoline motors are employed. Steam was represented on the entry list, but at the last moment, difficulties arose between the entrant and the committee regarding the fuel to be used. Unable to come to a settlement, the owner of the steamers withdrew from the test. It may safely be said that steam is dead in France. Last year two firms appeared, but both of these have practically gone out of existence since, and the firm that entered and withdrew is a newcomer of very little importance.

There are two cases of electric transmission, but this does not change the general rule that gasoline is all supreme in France, for the Kriegers employ a four-cylinder internal combustion motor driving a dynamo, the transmission only being electric and final drive by side chains. Another point of uniformity is in the final drive by side chains. With the exception of the De Dion-Boutons, with their special type of rear axle, side chains are found on every commercial vehicle entered in the heavy classes. Engines are invariably carried forward, and although in a few cases under a bonnet are more often placed under the driver's feet, or below his seat, in order to gain room for useful load. The only novelties in engine cooling were shown on the Malicet & Blin and Berliet vehicles. The former had a plain copper-tube coil radiator, with a belt driven fan placed directly in the center of the coil of tubes. Berliet adopted a radiator composed of plain vertical copper tubes uniting an upper and lower tank. This type of cooler has been employed on the firms taxicabs, but it is the first time it has been used on a heavy commercial vehicle. A useful addition was a steel guard across the front of the radiator to preserve it from shocks. Engine control has generally been simplified to the operation of a throttle lever or an accelerator pedal operating on the intake. The sparking point is fixed and engines are generally governor controlled to prevent racing.

Constructors have been left free in the matter of tires and wheels. While the army would prefer metal bandages, they are not made obligatory, the rule being that metal or steel can be used, and an estimate will be made of the wear and tear at the end of the test. Very few risk mounting their vehicles on metal bandages. Berliet, for instance, along with two or three others, adopts solid rubber in front and steel bands on the rear wheels, thus giving, so they claim, all the necessary protection to the mechanism, while reducing cost on the rear wheels. The great majority prefer to equip their vehicles all round with solid rubber tires. Saurer, who has the only trailer in the competition, adopts rubber for the wheels of the trailer in addition to the tractor.

Berliet, with Plain Tube Radiator, Novel Guard, and Distinctive Type of Steering Gear

What the Clubs Are Doing These Days

A. A. A. TO HAVE NATIONAL LEGISLATIVE CONVENTION

In Washington, in January next, the first national legislative convention under the auspices of the A. A. A. will take place. Announcement comes from Charles Thaddeus Terry, chairman of the association's legislative board, after consultation with the A. A. A. directors.

This will be the first legislative convention of its kind ever held. The summer meeting at Buffalo in 1908 considered both laws and good roads, though chiefly devoted to the latter proposition.

Plans are now under way to invite the Governors or their representatives from all the States in the country, and in view of the increasing interest in the subject of good roads throughout the Southern and far Western States, it is believed that the delegates from these localities will be particularly large. It has been found wherever the good roads subject becomes prominent it is at once followed by a demand for better laws regarding the use of the highways. The two chief matters that will be brought before the coming national convention will be the national registration motor law and the uniform State law. The national registration act will be reintroduced into Congress by Congressman Cocks, who had charge of the bill last year, and it is proposed to secure a hearing upon the bill before the judiciary committee during the time of the convention in Washington.

A. A. A. HAS THIRTY-ONE STATE ASSOCIATIONS

Thirty-one State associations are now included in the membership of the American Automobile Association, though one of these is the Hawaiian association.

According to figures provided by Secretary F. H. Elliott, in preparation for the annual meeting the latter part of the month, the New York State Association leads with 4,518 members, the Pennsylvania Motor Federation coming next with 3,113, and the Associated Automobile Clubs of New Jersey, third, with 2,156. Six organizations have a membership of over one thousand: Minnesota, Ohio, Southern California, Illinois, Massachusetts and Connecticut. Among the large number of clubs affiliated with the national body the latest statistics show that 40 have a membership of over 100. The Automobile Club of Buffalo heads the list with 1,827 members, followed by the New Jersey Automobile and Motor Club with 1,800, while the Automobile Club of Philadelphia is just short of 1,000. The Automobile Clubs of Chicago, Minneapolis, Cleveland, Long Island and Rochester each have over 500.

PHILADELPHIANS PLAN TO SAVE TOLL

Philadelphia, Nov. 1—The Automobile Club of Philadelphia continues its good roads work despite the near approach of winter. It has just issued an appeal to automobilists generally, asking subscriptions to a fund for macadamizing a stretch of road running from the second toll-gate on the Live Lexington pike to Sellersville. When completed, this bit of good going will enable automobilists to avoid a particularly bad stretch of road on the Hilltown-Sellersville pike, and incidentally save 30 cents toll.

PITTSBURG DEALERS' ASSOCIATION ELECTS MURRAY

Pittsburg, Oct. 25—The Automobile Dealers' Association of Pittsburg has again chosen W. N. Murray, of the Standard Automobile Company, as its president. The other officers are G. P. Moore, treasurer, and J. K. McKeogh, secretary and vice-president. The association is already making plans for the 1910 show, to be held in Duquesne Garden.

QUAKERS PROTEST AGAINST WILD-CAT MEETS

Philadelphia, Oct. 26—The Quaker City Motor Club does not purpose to allow future invasions of its particular bailiwick by outside promoters. A few weeks ago a combination aeroplane-automobile speed-fest was held at Point Breeze track, which, owing to a variety of causes, proved frosty, and the 6,000 spectators were decidedly sore when they filed out of the gate at sundown, having witnessed nothing more than a few mediocre match races, the aeroplane end of the meet having been abandoned owing to the high wind. At a meeting of the club's board of governors the following self-explanatory resolution, introduced by Richard Sellers, was unanimously adopted:

"We hereby enter a protest against the American Automobile Association granting sanctions to any individual or individuals to carry on a race meet such as took place on Saturday, October 16 last, at Point Breeze track, Philadelphia, for the reason that all such race meets are detrimental to the sport of automobiling, as they bring discredit to allied clubs and place the national organization in a compromising position before a patronizing public."

At the same meeting the contest committee took up the matter of Chairman Hower's recent edict compelling promoting clubs to make announcements on or before November 1 of their programs for the coming year or suffer the penalty of having their chosen dates considered of "secondary importance." As a result, it was decided to announce the following program, and put in bids for the dates specified: January 1-2, midwinter endurance run, subject to change, as the 2d falls on Sunday; April 30-May 1-2, roadability run; June 4, spring track meet; August 6, midsummer track meet; October 8, Fairmount Park race.

ENJOYABLE RUN OF BLUE-GRASS AUTOISTS

Louisville, Ky., Oct. 23—Members of the Louisville Automobile Club participated in an enjoyable sociability run recently. Starting from Third Avenue and Chestnut Street 15 cars went humming off to Fisherville over the Taylorsville pike. Dinner was served at the Blue Rock Hotel, Fishersville, and the return trip was made over good roadways via Frey's Hill and the West Point pike, arriving home at 6 o'clock. The route covered some of the most picturesque territory in Jefferson County. It is planned to inaugurate a series of such trips during the winter.

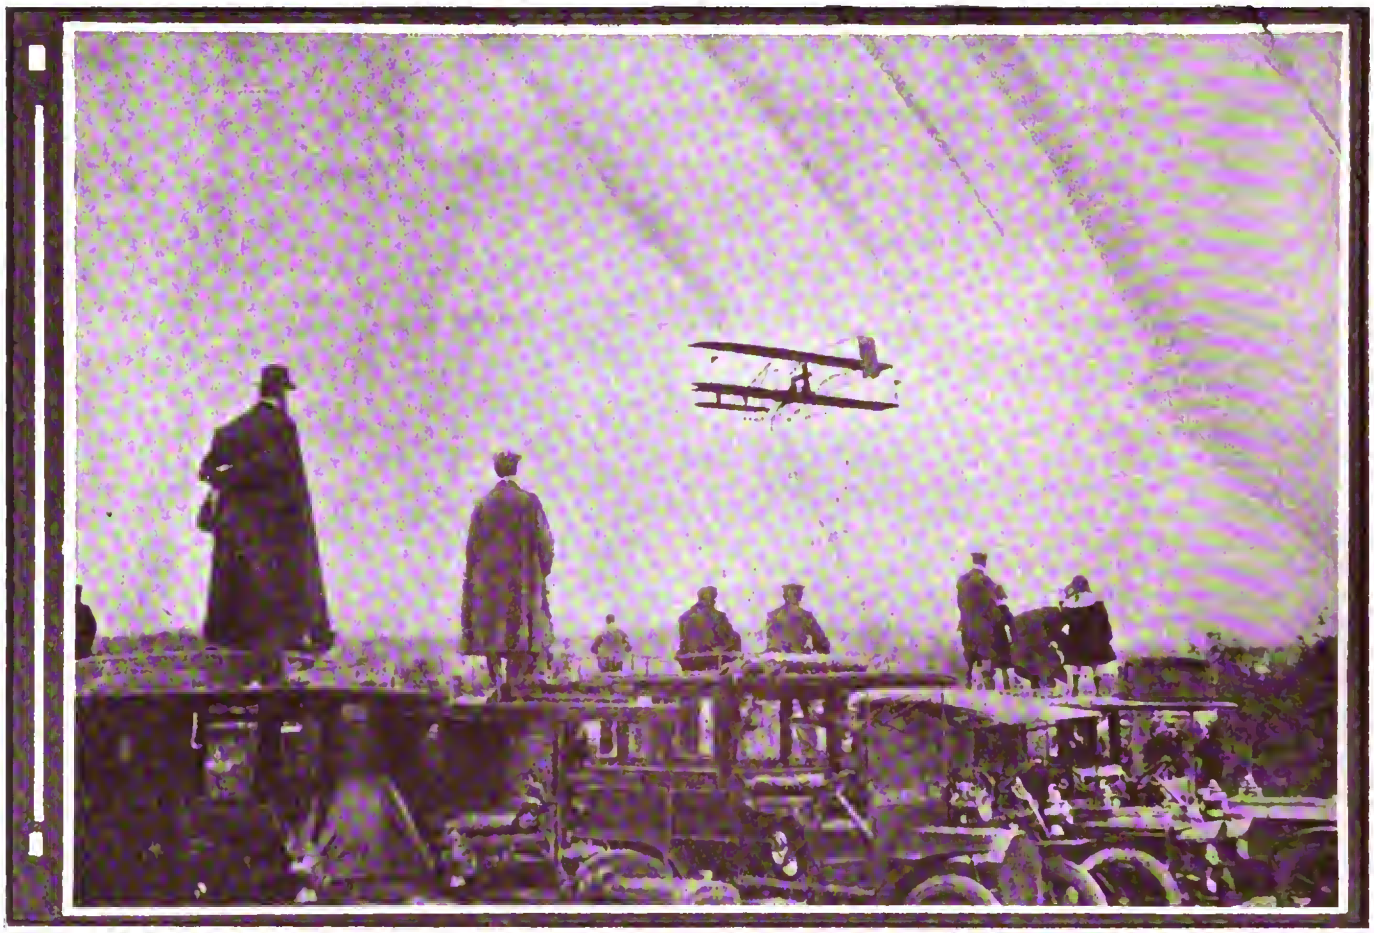
A vigorous campaign to increase the membership of the local club is under way. The membership is now 250, and it is hoped to increase the figure to 400. If this is successful the club will probably vacate its suite in the Louisville Hotel and build a home of its own.

SUCCESSFUL RACE MEET IN OKLAHOMA CITY

Oklahoma City, Okla., Oct. 25—The first race meet of the Automobile Association was a decided success, and most encouraging to the promoters. There were nine races, all match events between two cars except one, which was a five-cornered pursuit race. The most interesting was between a Hupmobile and a Ford, won by the latter in two out of three heats. The pursuit race was won by an E.-M.-F.. which also won two match races.

BALTIMORE CLUB LEARNS ALL ABOUT STEAMERS

Baltimore, Nov. 1—The last Tuesday evening of each month has been set aside by the members of the Automobile Club of Maryland as lecture night. The speakers will be prominent authorities on automobiles. At the first of these meetings Dr. H. M. Rowe, former president, discussed the White Steamer, during which he gave the club members some interesting and important technical points regarding the car.



Comte de Lambert, in His Wright Biplane, Rising from the Plain of Juvisy for His Journey Over Paris

LAMBERT'S FLIGHT WHICH STARTLED AVIATION WORLD

PARIS, Oct. 18—Paris was engrossed in its business and pleasure when the cry went up "an aeroplane." Instantly duties and pleasures were forgotten, every neck was craned, every eye was directed skywards towards the unknown aviator who had dared to fly over the most crowded city in the world. Advancing from the south, at a height of over one thousand feet, the identity of the aviator was at first unknown, and for some time the make of the machine was indiscernible. As it approached, advancing so steadily that it did not appear to move, but merely to grow larger, it was seen that it was a Wright biplane. But who could be its pilot? It was a nerve-racking exploit such as a Lefebvre would have loved to make. But Lefebvre is no more, and Comte de Lambert, the only other Wright pilot in the neighborhood of Paris, would never attempt such a supremely daring flight.

But it was Comte de Lambert. Less than half an hour before he had risen from the aerodrome at Juvisy in the presence of several thousand spectators, evidently for the purpose of making his usual mediocre flight in their presence. But, unknown to any one on the ground, Comte de Lambert had resolved to escape from the narrow limits of this flying ground hidden in a hollow. Fifteen miles away, in the center of Paris, Paul Rousseau was perched on the top of the Eiffel Tower waiting for the American biplane and the Russo-French pilot. He was the only man in the secret.

The wait was not in vain. After a couple of rounds of the field Comte de Lambert had risen to such a height that he was able to pass over the tops of the surrounding hills, had escaped to the vast plateau beyond, and was making a bee line for the Eiffel Tower, clearly visible in the center of invisible Paris. At the aerodrome, the spectators looked at the surprise written on one another's faces. They waited fifteen minutes, then half an hour, finally dismissing the subject with the reflection that the aviator had gone beyond the limits of the field and had been obliged to descend. Even Orville Wright, who had arrived on the field at the moment Comte de Lambert shot into the air, had no idea where the aeroplane had gone to.

Meanwhile a straight course was being made for Paris. The aeroplane passed over the flat, uninteresting country devoted to intense market gardening. It approached the crowded suburbs, causing the street traffic to stop and the factories to empty.

Gasoline Into Paris Without Duty

Now it had passed over the fortifications, while the octroi officials looked on helpless at the man who was taking gasoline into the city for the first time without paying duty. Now it was over the working class district on the south side of the River Seine. Thirteen hundred feet high it towered above the Pantheon, Les Invalides, even the Eiffel Tower, the highest monument in the world, the point of which had never previously been passed by other than spherical balloons. Paris gazed in amazement, too surprised to cheer the human being who was perched high up on those wood and canvas frames hovering over the city.

The tower was reached, the aeroplane passing over the point with a margin of about three hundred feet to spare. Then it appeared to turn westward, as if about to descend on the Issy-les-Moulineaux plain, where Henry Farman first flew a circular kilometer. Now it was heading east, now it was off due south. Evidently Comte de Lambert had been seeking his bearings, which he had lost while rounding the summit of the tower, and was now bound to his shed at Juvisy, fifteen miles away.

Comte de Lambert Circling the Eiffel Tower in Paris, in His Epoch-Making Flight in a Wright Machine

Again over the working-class portion of the city, over the fortifications, over the open country, parallel with the long, straight, pave-lined road becoming busy with automobiles returning to Paris, the artificial bird winged its way to Juvisy. As it left Paris its height increased until it was a mere speck in the sky with a large, gray cloud as a background. The tower is practically one thousand feet high. Comte de Lambert had cleared this by 300 feet. As he had risen still higher, it is safe to estimate that he was 1,600 feet from the ground. Formerly experts had quarreled as to whether Rougier or Orville Wright had risen 600 feet from the ground. Now a man had beaten all official records hollow.

As quietly as he had gone away, Comte de Lambert settled down on the aerodrome after encircling the ground twice in order to decrease his height gradually. He had been away exactly 50 minutes, during which time he had covered 30 miles, and performed the most astounding feat ever witnessed in aerial navigation.

Machine Was Standard Type Wright Biplane

The machine with which the flight was made is the standard type of Wright biplane, built for the French Company at the Astra workshops. It was the first flight of importance it had made, for this particular machine had only been delivered at the aerodrome a few days before to be tested by Comte de Lambert before being handed over to its owner, a Russian sportsman. The owner must have been satisfied with the trial flight. The motor employed was also the standard type built at the Barriquand & Marre factory from Wilbur Wright's own designs. It was the same type of motor as the one with which Wright made all his early flights in France, with a few minor improvements and rather better workmanship than the Wright brothers had been able to furnish with their limited resources. The first motor, built in America, perished in October, 1908, when a connecting rod broke and went through the bottom of the crankcase. The Barriquand & Marre company had already been at work and were able the next day to supply the same type of motor built in their shops. Since then this motor has been used on all French-built Wright machines. It is of the four-cylinder type, cylinders cast separately, and cooled by force feed water circulation. There is no carbureter, the gasoline being injected into a collector and aspired from there into each cylinder. Ignition is by high-tension Eisemann magneto, this being one of the changes made since the engine came into France, the original one having low tension ignition. Valves are in the head, the inlets being automatic.

BISHOP RE-ELECTED AERO CLUB PRESIDENT

With a vote of 205 to 13, Cortlandt Field Bishop was Monday night last re-elected to the presidency of the Aero Club of America, at the meeting held in the clubrooms on East Forty-second street. The somewhat limited quarters were crowded to suffocation, which elicited the oft-repeated statement that now and then a contest is a good thing in the life of any club. These were the directors elected: Cortlandt Field Bishop, Charles Jerome Edwards, A. Holland Forbes, J. C. McCoy, and Samuel H. Valentine. The selection of these five means the naming of Mr. Bishop as president, Mr. Forbes as first vice-president, Mr. McCoy as second vice-president, and Mr. Edwards as treasurer.

The opposition failed to obtain the strength anticipated, for the belief was general that Mr. Bishop's excellent services abroad this year deserved a continuance in office in 1910, when the two big aeronautic events of the world will take place in America and under the auspices of the Aero Club of America.

Strange Italian Dirigible Accident—When the Italian military dirigible Uno Bis landed near Rome after a successful voyage from Naples, Lieutenant Rovetti, in keeping the crowd back, stepped too near the whirling propeller, which struck and killed him.

LATEST FROM GENERAL MOTORS

Detroit, Nov. 2—Michigan holders of General Motors common stock have been notified of the action of that company in declaring a dividend of 150 per cent., payable in common stock November 15. Present common stock of the General Motors Company amounts to $5,500,000. With the dividend just declared the outstanding common stock will be increased to $13,750,000, still leaving more than $26,000,000 of the $40,000,000 common stock authorized by the stockholders some time ago in reserve.

Cause for rejoicing on the part of stockholders is not alone dependent on the dividend just announced, the showing in other directions during the first year of the General Motors Company's existence being decidedly favorable.

According to W. C. Durant, president of General Motors Company, at the close of business September 30, marking the end of the year, there was a surplus in excess of $7,000,000. Charging off all depreciation, patents and doubtful accounts, there still remained a surplus of $1,040,000, a decidedly comfortable showing for so short a period.

During the year just closed constituent companies making up General Motors produced an aggregate of 28,550 automobiles, the volume of business represented being $34,000,000. Forecasts for the coming year are even more favorable, Mr. Durant stating that orders have been secured for 68,000 cars, representing a sale value of $60,000,000.

Rumors are rife regarding further additions that are to be made to the long string of automobile manufactories throughout Michigan comprising the General Motors Company. Every time news gets dull it is safe to speculate on what Mr. Durant and his associates are about to do. So far as the local field is concerned there appears to be little opportunity for further enlargement, unless it might be through absorbing some of the newer concerns. Furthermore, the General Motors Company now is in a position in its own plants to manufacture any and every size of car on the market, thereby eliminating one reason for further extensions that existed even a few months ago. However, with its past record still fresh in mind, it is not safe to predict absolutely what will happen. The Elmore Manufacturing Company is the latest reported addition to the General Motors list. but this has not been confirmed by official announcement.

FOR AUTOMOBILE INSURANCE ONLY

Indianapolis, Nov. 2—With private wealth estimated at $50,000,000 behind it, and with an authorized capitalization of $1,000,000, the Automobile Insurance Company of America has been organized in this city. The general offices will be located in Indianapolis, while branch offices will be located in all of the principal cities in the United States.

It is believed that the company is the first to be organized exclusively for automobile risks. The officers are: President, D. M. Parry, of the Parry Automobile Company, Indianapolis; vice-president, L. N. Littauer, a millionaire glove manufacturer of New York City and former Congressman; secretary, Ernest B. Thomas, of Rushville, and treasurer, John W. McCardle, of this city. a member of the State Board of Tax Commissioners.

REGAL WILL HAVE CANADIAN BRANCH

Detroit, Nov. 1—Another forward step has been taken in the foreign invasion planned by Detroit automobile manufacturers, the Regal Motor Car Company having decided to establish a Canadian branch in Windsor, just across the border from this city. A new company is being formed, including the officials of the present concern and E. N. Richards, of Windsor, who will be manager of the Canadian factory. For the purpose of supplying the Canadian trade a $100,000 plant will be established, with a capacity of five cars a day, the output to be increased as conditions warrant. A new factory will be built as soon as a suitable location can be found.

MASSACHUSETTS AUTO TRAFFIC 33 1/3%

Boston, Nov. 1—The results of the road census taken by the Massachusetts Highway Commission, the week beginning Oct. 10, which are being compiled at the offices of the board in this city, indicate that under normal traffic conditions on the State roads, automobile travel is not as heavy as in mid-summer, when there is much touring. At the census taken in August the tabulations and calculations showed that 42 per cent. of all the traffic was motor-driven, but from the results that have been calculated in the October census it is apparent that the motor-driven traffic is about 33 1-3 per cent. of the total. The October census was taken at 237 stations scattered all over the State, their locations being the same as in the case of the August census.

The point of heaviest motor-vehicle traffic revealed by the October census was the Saugus River bridge connecting the Lynn State road with the Metropolitan boulevard along Revere Beach. There the enumerators counted an average of 715 vehicles a day and 90 per cent. of them were automobiles. The point of least motor-vehicle traffic was in Nantucket. As this place has a special automobile exclusion law, the traffic registered 100 per cent. horse drawn. Along the Cape there were several points where above 80 per cent. of the traffic was horse drawn. and in not a few places in the vicinity of Boston the automobile traffic was from 50 to 70 per cent. or more.

The heaviest traveled point in the State according to the October census was in Beverly, where an average of 1,475 vehicles were counted each day, 58 per cent. horse drawn and 42 per cent. motor driven. In the August census the heaviest traveled point was in Lawrence, where the average daily traffic was 2,440 vehicles, 66.39 per cent. horse drawn and 33.61 per cent. automobiles. In the October census this point showed an average of 1,222 vehicles.

PHILADELPHIA SHOW IN INSTALMENTS

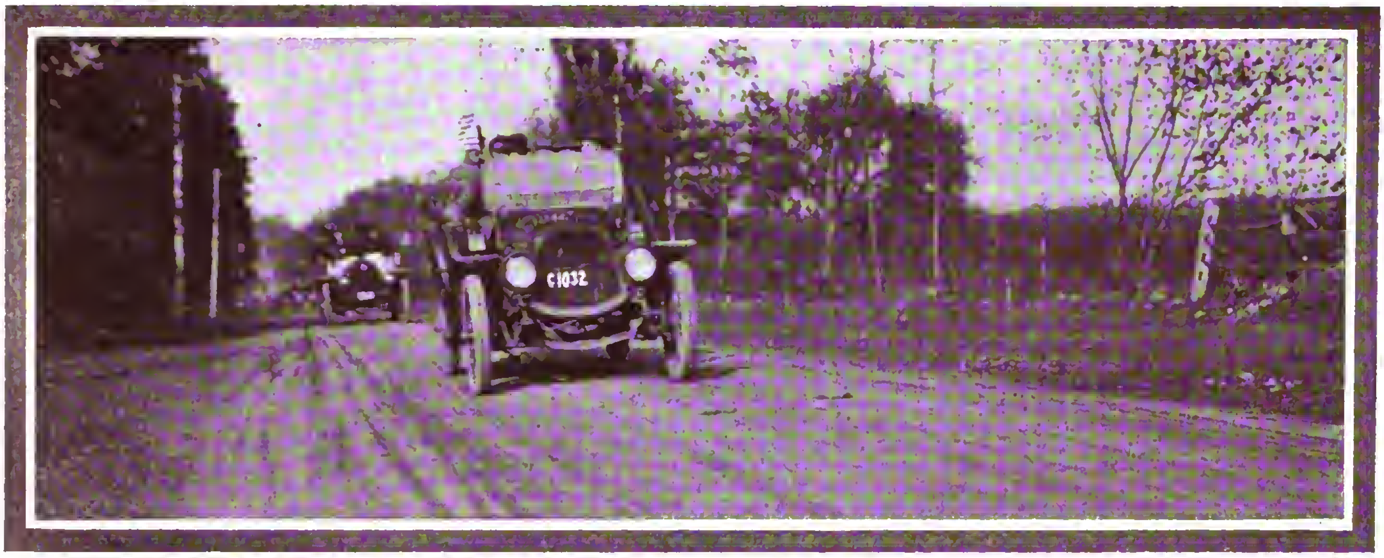
Philadelphia, Nov. 1—Blocked in their desire to get the use of the Second Regiment Armory for the annual exhibition, the show committee of the Automobile Trade Association of Philadelphia made arrangements last week for holding that affair in the Third Regiment Armory, at Broad and Wharton streets. A trifle smaller than the Second Regiment building, the downtown structure is half a mile nearer the center of the city. The inadequacy of the building to the purpose will be partially overcome by the decision of the show committee to erect on an adjoining lot a temporary structure, 40 x 200 feet in dimensions. And even with this addition, the amount of space at the disposal of the committee will fall so far short of the requirements that it has been decided to run the show two weeks—January 15 to 29—instead of one, as originally intended.

At the end of the first week the exhibitors will be rooted out, bag and baggage, to make room for the second instalment of the show. It was the only solution of a problem which, with each succeeding year, has become more difficult.

A movement is now afoot to provide Philadelphia with a suitable building, and it is the hope of the committee, Messrs. J. A. Wister, W. J. Foss and J. L. Gibney, that the 1911 exhibition will hold forth therein. Secretary J. H. Beck has established offices at 216 Odd Fellows' Building.

DATE SET FOR WASHINGTON SHOW

Washington, D. C., Oct. 30—A meeting of the local automobile dealers was held to-night and it was decided to hold an automobile show at Convention Hall during the week beginning January 24, which is the week following the close of the Philadelphia show. B. C. Washington, Jr., who has managed the last three shows, has again been placed in charge and is rapidly getting his plans in shape. The fact that more than sixty-four different makes of cars are handled in this city would seem to insure the success of the show. Decorations will be uniform.



State Highway Commissioner MacDonald Leading the Procession at Opening of Berlin Turnpike

EXTRA ENTHUSIASM OVER NEW ROAD

HARTFORD, CONN., Nov. 1—"Obey the law," is the edict of the Hartford police, who have been very active of late in nabbing offenders on the new Berlin turnpike which was opened recently. A few days ago a New London chauffeur came through town without a front license tag. He said that he did not know that one was required. A special session of the police court was held for his benefit, as he wished to leave in the morning, and he was fined $7 and costs. George A. Pickett, a prominent New Haven automobilist, was arrested in Maple Avenue, the Hartford end of the Berlin turnpike. He was fined $15 and costs, and took an appeal to a higher court. The commission intends to stop those who are trying to make the seven-mile stretch a race course.

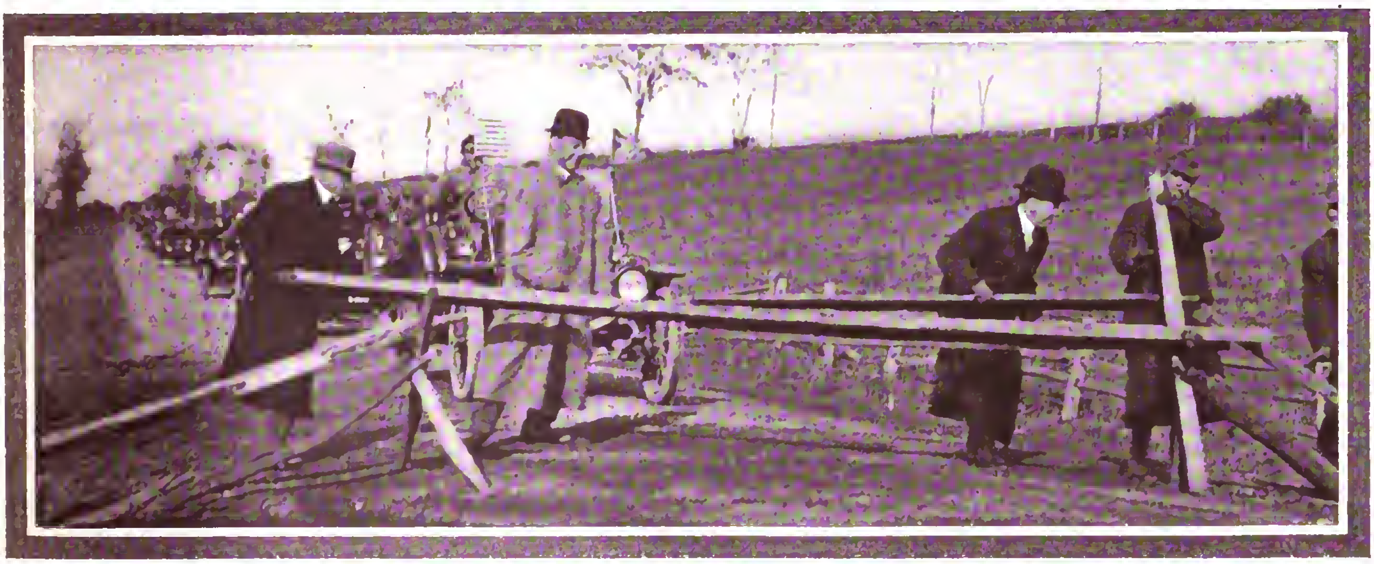
PLANNING FOR 1910 CONNECTICUT RUN

HARTFORD, CONN., Nov. 1—The all-Connecticut endurance run is the latest topic in the contest committee of the Automobile Club of Hartford. At a meeting held Friday evening the committee discussed a run to last four days, in the itinerary of which nearly every city in the State would figure. The meeting was called at the request of the American Automobile Association, which wished to know just what the Hartford club had on the board for 1910. The idea of a long endurance run seems to meet with popular favor, and it is believed that such a run could be successfully promoted, with a possibility of over 100 entrants. The distance would be divided into day's runs, radiating from Hartford as central control, the cars returning there every night. Connecticut offers all sorts of going; level country with good roads, steep hills and an occasional mountain ascent. The total distance would in all probability be 500 miles or more, and the club would offer a trophy valued at $300 to $500.

DETROIT'S VICINITY MAY HAVE ROADS

DETROIT, Nov. 1—That the good roads movement is to be given impetus in this vicinity the coming summer is manifest from the fact that a committee including representatives from various automobile manufactories and retail establishments has perfected arrangements for the building of several miles of good roads in Wayne County. The Michigan State Automobile Association has also interested itself in the matter, and tangible results of a decidedly welcome nature are promised.

The rumor that Detroit is to have a speedway solely for automobiles, built along the lines of the one in Indianapolis, is strengthened by the resignation of E. A. Moross, manager of the Indianapolis Motor Speedway, for the avowed purpose of returning to Detroit to become associated with a company that is to build a speedway here. Moross has for several years been a prominent figure in automobile racing circles.



Highway Commissioner MacDonald Breaking Down the Fence, Berlin Turnpike Opening

In the Woods of Washington State with a Franklin

This photograph, taken near Pomeroy, shows W. W. Richardson and party in their Franklin touring car. Mr. Richardson is the owner of a large grain ranch, and in June, 1908, he drove his car from the H. H. Franklin factory in Syracuse, N. Y., to his Washington home.

More about Bumper Patents—The temporary injunction obtained by the Turner Brass Company against the Vanguard Mfg. Co., restraining the latter from manufacturing bumpers infringing on a certain patent, has brought from the Vanguard Company an authoritative statement of its position in the matter. According to this statement, the Vanguard Company has long since discontinued the manufacture of the style of bumper claimed to be an infringement, for the reason, it is said, that this style was found unsatisfactory in service. Nevertheless, the injunction will be contested in court, in order to establish the fact that the Vanguard Company is not and has not been infringing on any patents whatsoever.

Baldwin Buys Auto Truck—The Baldwin Locomotive Works has joined the users of auto trucks. The first machine bought by this company is a Saurer, which is to be used between the company's works in Philadelphia and one of the foundries and branch works some thirteen miles distant. It is expected that the truck will be able to make three round trips a day, when necessary. The features of the truck include a compressed air system, which operates one set of brakes and also a self-starter for the engine. It has a four-speed gear, the highest gear giving fifteen miles an hour.

New Kline-Kar Scores—Two Kline-Kars took part in the sociability run of the Harrisburg, Pa., Motor Club from Harrisburg to Cornwall and return, and both acquitted themselves creditably in the gymkhana contests which were held at Cornwall. Robert Morton, the manager of the Keystone Motor Car Company, won the vibration contest with his six-cylinder, 40-horsepower Kline-Kar, and J. A. Kline, general manager of the B. C. K. Motor Car Company, which makes the Kline-Kar, won the potato race with his 6-40 roadster.

White Concentrates in Cleveland—On November 1 the advertising office of the White Company will be moved from its present location, 1402 Broadway, New York City, to the White factory in Cleveland. R. H. Johnston, who for the past six years has been in charge of the advertising of the company, will continue his duties at the new address. Mr. Johnston will change his place of residence from the Engineers' Club, New York, to the Hollenden Hotel, Cleveland.

IN AND ABOUT THE AGENCIES

American Simplex, Boston—New salesrooms in the Hub City have just been opened at 261 Dartmouth street, one of the best locations in the city. This branch will be in charge of W. Mason Turner, as manager. The recent victory of this car in the Munsey tour has done much to advance the sales in this part of the country, and the new branch was opened to take care of the increased business resulting from that victory. This company has done much explaining to counteract the impression that it was its car which won at Lowell.

Miller Supplies, Atlanta, Ga.—Chas. E. Miller, manufacturer and jobber of automobile supplies and accessories, opened a branch house in Atlanta November 1, at 66 Edgewood avenue. It is expected to carry on hand a large stock of supplies to meet the Southern demand. Prices will be the same f.o.b. Atlanta as at the other branches, in this way saving customers the freight and express charges, as well as several days' time.

Cadillac, Pittsburgh—The McAlister Motor Car Company has succeeded the Imperial Motor Company as agent for the Cadillac. The firm is composed of R. P. and William J. McAlister, and will retain the location at 5906 Penn avenue.

Mitchell, Grand Forks, Mich.—A. O. Anderson and M. L. Strong have formed an automobile company to handle the Mitchell, and have been assigned ten counties in northeastern Michigan.

Marmon, Chicago—W. G. Tennant, of Tennant Motors, Ltd., has taken the agency for the Marmon line in Chicago and northern Illinois, and has contracted for 75 cars.

Croxton-Keeton Agencies—Contracts for the sale of Croxton-Keeton cars have been made with the Sanford Automobile Company, of Denver, and the Rooklidge-Gilmer Company, of Salt Lake City.

Moon, Pittsburgh—The Agency for the Moon Motor Car Company in this city has been secured by L. A. Randal, who already handles the Hupmobile.

Overland, Detroit — The Overland Sales Company has ben organized to represent the Overland in Detroit, with a salesroom at 295 Jefferson avenue.

PERSONAL TRADE MENTION

L. Isenberg, junior member of the Roman Automobile Company of Philadelphia, has gone to Washington, D. C., to take charge of the branch house which the concern recently opened there.

"Tom" **Berger,** the noted Philadelphia driver, has signed with the sales force of the Motor Company, agents for the Premier car.

RECENT INCORPORATONS

Rambler Automobile Company of New York, New York City—Incorporated with a capital stock of $25,000 by T. H. Beardsley, G. Tiernan and F. H. Purcells, to manufacture and sell automobiles.

Midland New York Company, New York City—Incorporated with a capital stock of $50,000 by M. Boyle, A. F. Britton and E. M. Boyle, to manufacture and sell automobiles.

RECENT TRADE PUBLICATIONS

Peerless Motor Car Company, Cleveland—The last word in the development of automobile catalogs as works of art must be granted the Peerless. Many delightful country scenes form the head and tail pieces, and these are printed in colors, giving the effect of water-color paintings. Even the mechanical illustrations are tinted to emphasize the points. There are 36 pages, 8 by 10 inches in size, of which a third are occupied by full-page illustrations. The covers are double, of stiff, heavy paper in terra cotta, with an ornamental design in shades of brown and gold. In pardonable enthusiasm over the artistic side of the catalog the mechanical side might well escape notice, yet this has not been neglected. The reading matter is straightforward exposition, and is all devoted to the car, without the high-flown verbiage which is so often allowed to obscure the points which the reader really wishes to have made clear.

The Rambler Magazine—The "Dealers' Number" of this product of Thos. B. Jeffery & Company seems rather above the average of house publications. Its 60 pages, of fine glazed stock, contain descriptions of the 1910 Rambler models, a story of the five thousand-mile test runs of the first two of the new series cars, and an exposition of the selling system of the company. Illustrations are good and unusual in number, including photographs of many of the machines and processes in use in the Rambler factory, pictures of garages and agencies, cars in various contests, etc. A signed photograph of Thomas B. Jeffery forms the frontispiece.

The Locomobile Company of America, Bridgeport, Conn.—The 1910 catalog of this well-known maker is a splendid example of commercial literature, being modest in size and design and at the same time attractive in its neatness and simplicity. It is bound in a double cover of brown linen, the front of which bears the title "Locomobile—1910" in red. The type is small but distinct, and set off by red side-heads. The illustrations, although not numerous, are well chosen and clearly printed, always emphasizing the right point. Specifications are complete and conveniently arranged.

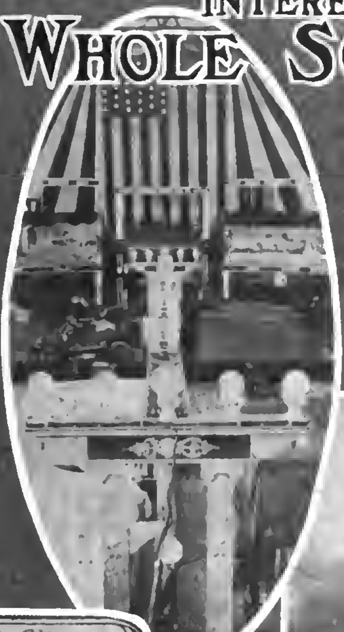
Gilbert Mfg. Co., New Haven, Conn.—The advance catalog for the season of 1910 contains an extraordinarily varied line of supplies, all of which are manufactured by this firm. Tire cases are a specialty, as well as irons for holding spare tires; but also included are inner tube cases, spark plug cases, tire sleeves, starting crank holders, storm aprons, tool kits, waterproof magneto covers, fan or oiler belts of coiled wire, joint and steering connection boots, lamp covers, robe rail boots, racing helmets, and spare tire locks. The Bowers carbureter is also listed.

VOL. XXI NEW YORK—THURSDAY, NOVEMBER 11, 1909—CHICAGO No. 20

THE AUTOMOBILE

ATLANTA'S NATIONAL SHOW INTERESTS THE WHOLE SOUTH

Mayor Maddox, Asa S. Candler, Clark Howell and other Members of the Chamber of Commerce, who Officially Opened the Show



A Glimpse at the Inside

Exterior View of the Auditorium Armory Where Show Is Being Held

ATLANTA, GA., Nov. 8—This wideawake city is undoubtedly the busiest place in the whole South, and the coming of automobiles explains the whyfore. In giving the "Gate City" a National Show the N. A. A. M. acted wisely, for the event has involved the pride of the municipality, which is exceedingly great, and involves the inhabitants as a whole, besides all officialdom and a thoroughly surcharged press. Such universal enthusiasm is a revelation to the follower of the show circuit whose experiences began with that exhibition in New York's big amphitheater when the bicycle grudgingly gave not much more than a corner to the rival who soon gained the center of the stage in prodigious bounds.

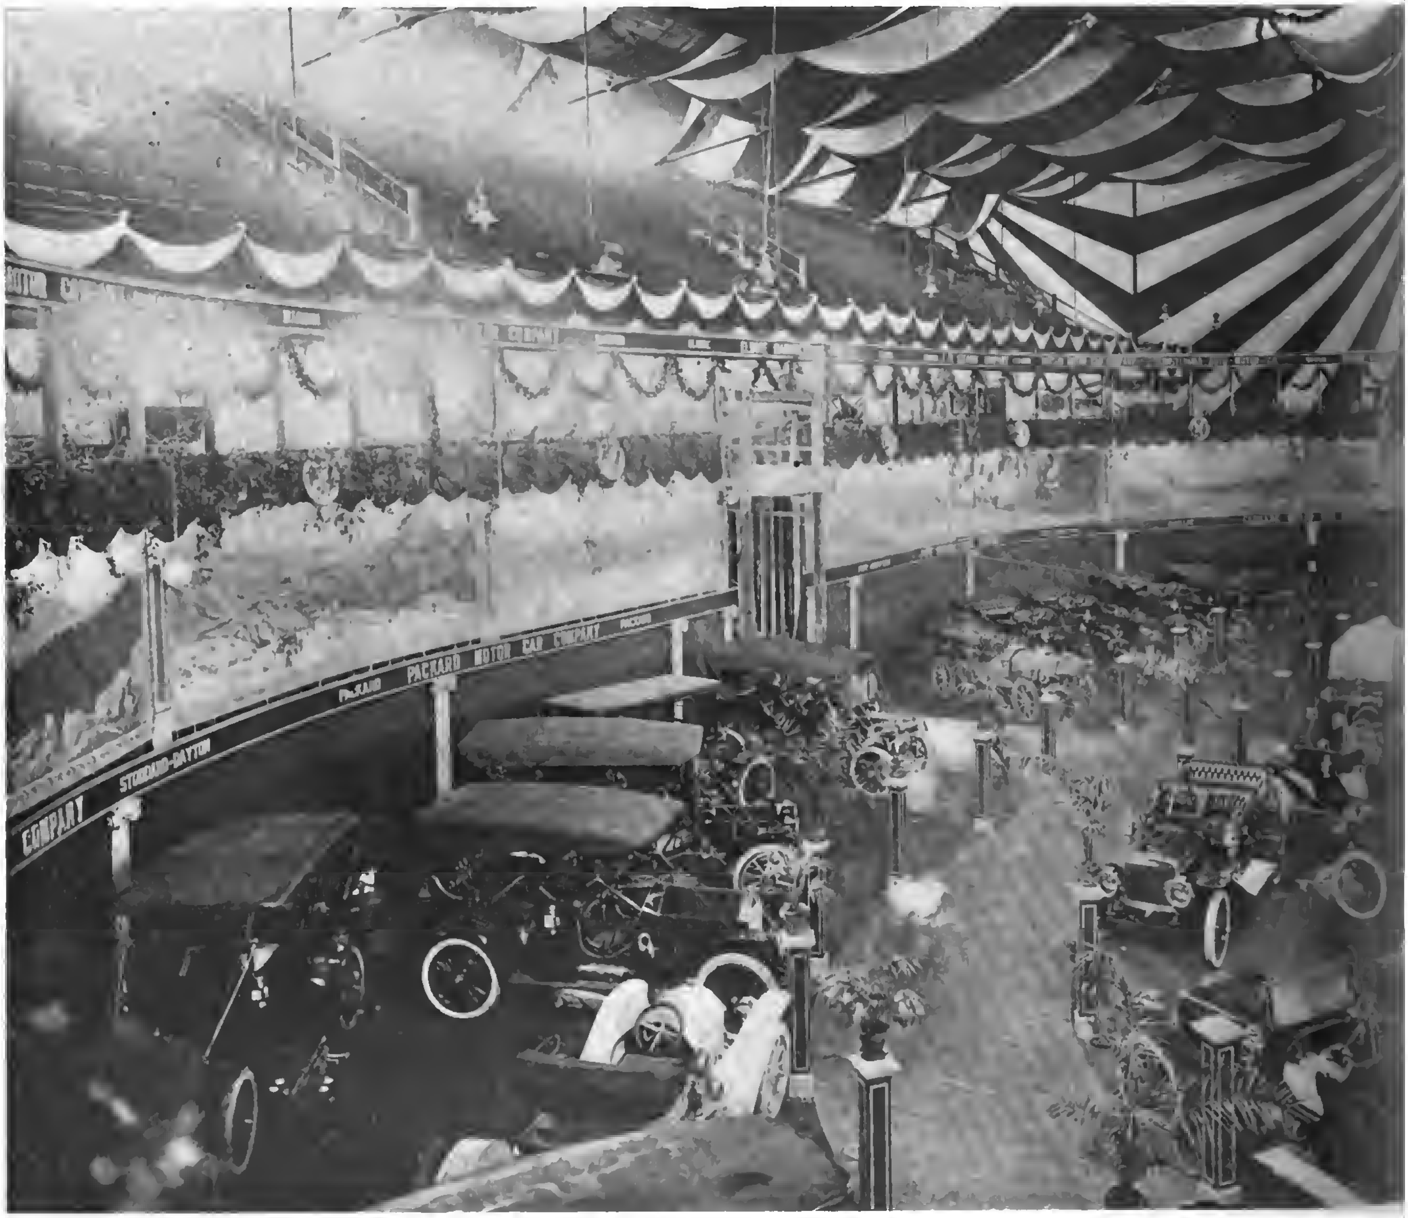
When the new Auditorium-Armory opened its doors on Saturday afternoon last and invited the public to have its first look at the segregation of 1910 models, the persistent efforts of Managers Miles and Reeves had netted the installing of all exhibits but three, with decorations complete and artistic. The prevailing colors are red and white, and a plenteous use of American flags, the effect being pleasing and enlivening, and further embellished in the main hall with paintings depicting the automobile in varied settings.

Of course, all could not have spaces in the heart of the building, and considerable ingenuity had to be employed to take full advantage of all the opportunities scattered about the structure, which, however, is being explored to its most inaccessible parts by seekers for automobile information and instruction, for please keep it in mind that this is the first National Show ever held in the South, and the aforesaid South is filling Atlanta's hotels and rooming houses to full capacity.

Down here, coincident with the resultful cry for good roads, is the buying of autos to travel over the highways before they are built. Again, while it is true that the cotton crop is only a two-thirds one, the Georgia yield is in excess and the deficiency is in Texas, and with the price hovering around 15 cents there is going to be some sixty million dollars ahead of previous years. The deduction is that there will be some dollars with which to buy autos; and the large attendance is an indication that the prophesy stands an excellent chance of fulfillment. Before the show was a day old there came the usual reports of sales, and, discounting the zeal of the salesmen, there remains enough fact to prove the wisdom of those who argued in favor of a Southern display of up-to-date models.

In the opening of the show on Saturday afternoon there were some introductory festivities such as are dear to the heart of the Southron, which means that speeches figured therein with musical accompaniment. Mayor Maddox contributed the words of welcome in language befitting the occasion, followed by Asa G. Candler, president of the Chamber of Commerce, who was flanked by prominent members of that body. These included a notable contingent of the leading business men of the city, prominent among them being Clark Howell, editor of the Atlanta *Constitution*, and one whose efforts did much toward bringing a National Show to Atlanta.

Asa Candler is an Atlantian who has hewed his way to success and fortune, and now he is ever ready to do big things for his home city, though the story of his life tells of Georgia "Cracker" antecedents. But now he is rated by many as Atlanta's best asset from a business standpoint, and his belief in the place is indicated by his enormous real estate holdings. In the course of his speech opening the show Mr. Candler said:



In the Vast Amphitheatre of the Atlanta Auditorium-Armory, Where This Week Is

"Atlanta's automobile exposition marks an era in the development of the wealth and in the quickening of the progress of the Southeastern States. When the matter was proposed we undertook to make it an exposition such as no city of equal size in the world has ever had. We are here assembled to formally open this exposition in the fulfillment of that purpose. This exposition is setting forth in motion forces which will do more for the construction of good roads than has hitherto been accomplished. To increase interest in the exposition two great newspapers undertook to locate a great national highway, over which a successful contest tour has taken place from New York City to Atlanta. Another great paper of this city has aroused marked enthusiasm in roads building by inaugurating a series of tours from every part of the State to the capital. In furtherance of the same great end, and moved by an impulse characteristic of Atlanta's great public-spirited citizens, a company has constructed a speedway unsurpassed, if indeed we may not say unequalled, by any similar track in the world.

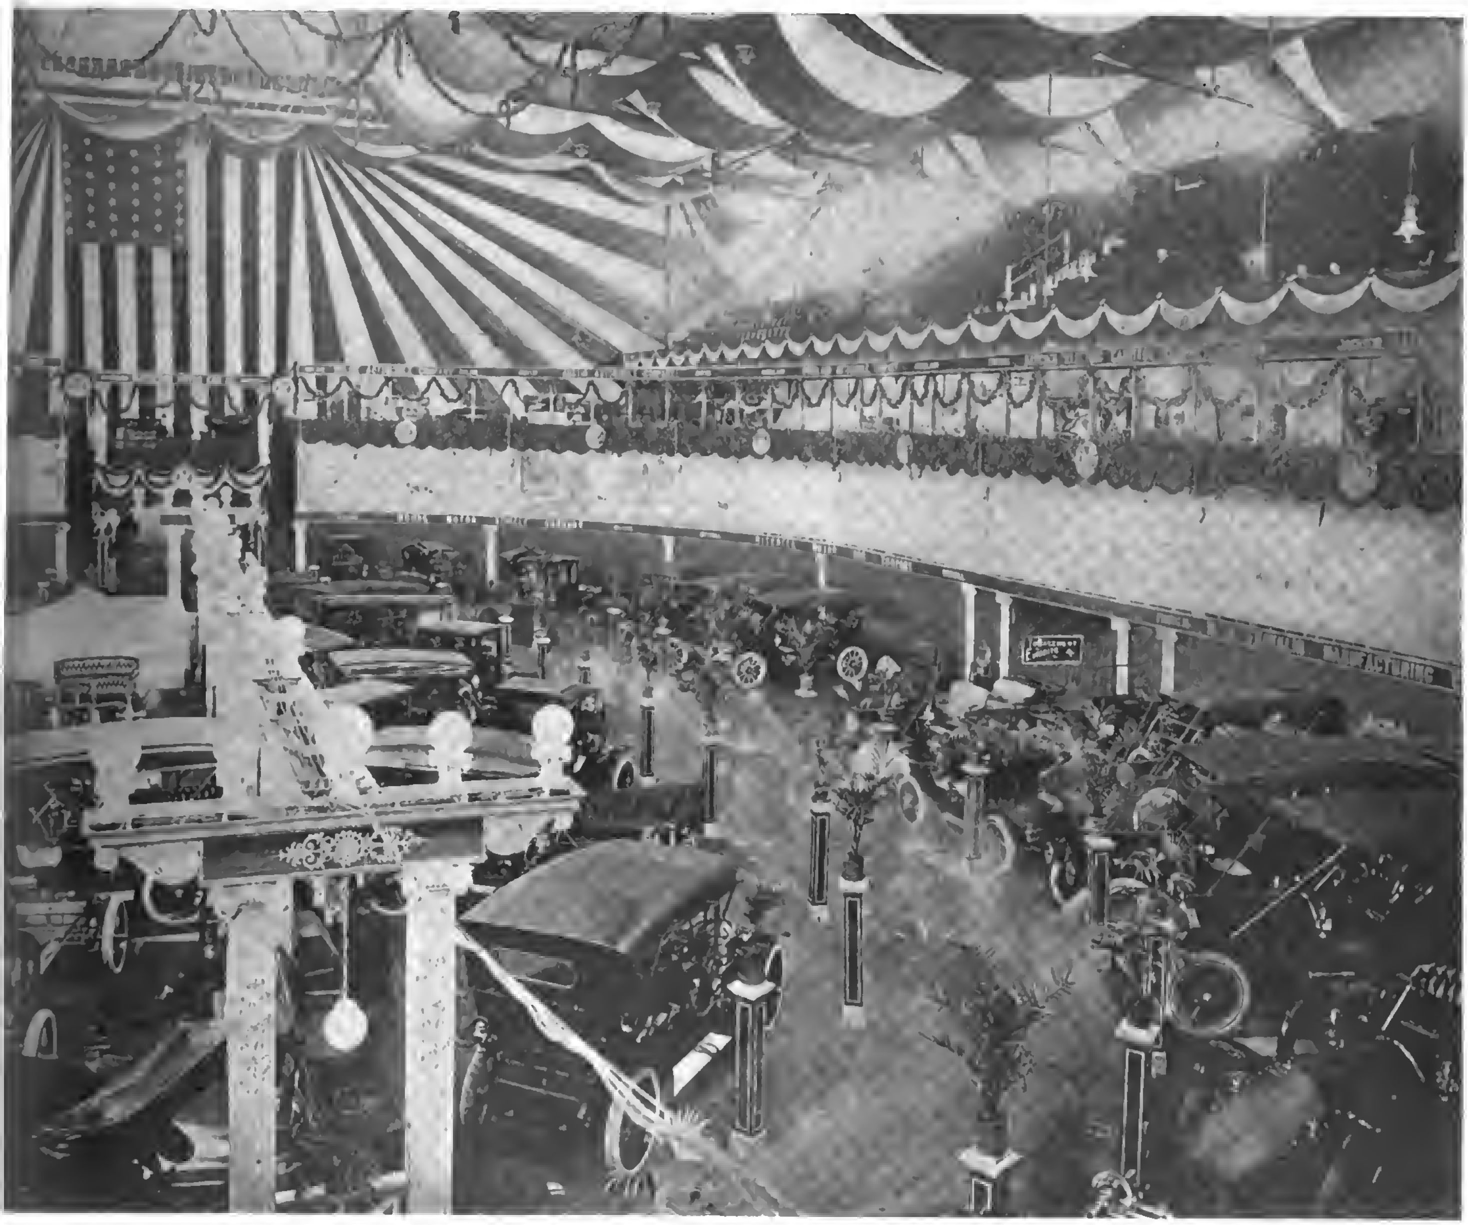
"If time permitted it would not be difficult to show that influences flowing from this exposition will promote more general and intimate association and a better understanding among the people. Distance divides, and that which sets distance aside begets acquaintance, which in the end ripens into friendship. Antipathy between town and country is removed when a method is found, and has come into common use, which brings the people from the country to the town quickly and safely, and sends the townsmen into the country with equal speed and facility. It was but yesterday when it was scarcely safe to operate an automobile in some parts of the country, so great was the prejudice against the horseless carriage. This prejudice is rapidly passing; in fact, is about gone. The people are coming to see that the automobile is an admirable and efficient instrument for promoting both the happiness and usefulness of their families. Besides the contribution which the automobile may thus make to the improvement of family and social life, it will do more to increase the wealth of the country. Man can never be in two places at the same time, nor command the sun to stand still; but by this invention he can cover more ground between suns and thereby bring more things to pass before dark."

Following the speechmaking the Fifth Regiment band played in succession "America," the "Star-Spangled Banner" and "Dixie," the latter selection, of course, evoking the real thing in the way of the old Rebel yell. Then the show was in full swing.

All this happened in the afternoon with a full house, which was renewed in the evening with an even larger attendance, though in connection therewith it was to be noted that the Atlantians are early seekers of their beds, for by shortly after 10 o'clock the crowd had thinned out most perceptibly.

In the main hall the luckiest drawers of spaces were Peerless, Oldsmobile, Ford, Premier, Pierce and Winton, which makes occupy the center. Around the outer circle are Cadillac, Pope-Hartford, Packard, Stoddard-Dayton, Maxwell, Stevens-Duryea, Franklin, Mitchell and Woods, while under the tiers of seats are Ohio, Studebaker, Selden, McIntyre, Standard, Columbus, Cartercar, Moon, Metz, Rauch & Lang, Renault, Hupmobile and Speedwell. In Taft hall there is a comfortable arrangement of Glide, Rambler, Reo, White, Locomobile and Mora.

Attracting immediate attention as one enters the building in the main lobby are Marion, Knox and Lambert. Down in the basement are the ones who rate themselves unfortunate, but there is light and room. This contingent includes Petrel, Wav-



yed the Choicest Products of America and Europe's Leading Automobile Manufacturers

Looking Down the Aisle in One Section of the Mezzanine Floor Where Many Prominent Exhibitors Had Space

erly, Streator, Sultan, F-A-L car, Cole, Inter-State, Great Western, Randolph, Autocar, Black and Rapid.

The mezzanine floor occupants in the main hall are happy in looking down upon the others, and to their elevation it is an easy climb. These include Matheson, Brush, Pennsylvania, Hudson, Stearns, Elmore, Marmon, Chalmers-Detroit, Pullman, Apperson, National, Baker, Jackson, Babcock, Overland, Austin and Moline. The entire list makes clear that the show is a representative one of the industry, and the South is not having a look at a skimpy lot of cars, for scarcely a name of note is among the missing.

In the accessory division it was not to be expected that the list would be complete, though leaders in each line are to be seen. But the patrons of the show are to be observed spending a goodly amount of time at the accessory booths which are scattered here and there to fill in any advantageous opening left over after the car allotments had been attended to.

Commenting upon the show now in progress, Manager S. A. Miles had this to say:

"The manufacturers are looking forward to a satisfactory business during this first National show in Atlanta, and it is fair to assume that if the event is as successful as they anticipate, the industry will be called upon to support three instead of two annual National events—New York for the East, Atlanta for the South, and Chicago for the West."

Telling of the preparations for the show here, Alfred Reeves, who has shared the management jointly with Mr. Miles, gives facts and figures that compare with the other National exhibitions. "Handling an automobile show simply adds to the old story of perfect organization, made a bit more difficult by the fact that plans for these affairs are somewhat of a temporary sort, hastily devised and carried out by men trained quickly for their work, somewhat as artists are trained for a big stage production put on after a short rehearsal. Since the adoption of uniform decorations the work of preparation has been greatly reduced, and the beauty of the exhibition as a whole has been increased most perceptibly. This show is effectively neat and artistic."

HOW ATLANTA ENTERTAINS HER AUTOMOBILE GUESTS

ABILITY to meet unusual conditions has always distinguished Atlanta and her people, but no better instance of their readiness can be recalled than the preparations that have been made for the guests of automobile week. The Chamber of Commerce was the rallying center, but President Asa G. Candler called a meeting of business men irrespective of membership. Committees were appointed on information and public comfort, public safety, and entertainment, and liberal appropriations were made for their use.

The committee on information assumed the duty of finding lodgings for the visitors. Local newspapers contributed space for announcements urging those willing to take boarders to send in their names. These notices, however, brought replies offering accommodations for but one thousand people. Then canvassers were sent out. They visited every reputable residence portion of the city within two blocks of a car line. Each canvasser was armed with blanks, which he filled out at the dictation of the householder. The particulars recorded were the family name, street number, nearest car line and cross street at which the visitor should alight, whether or not meals would be furnished, and the price of lodging or the price of meals and lodging. Those who could offer storage for one or more automobiles were also listed.

The canvassers visited about 3,500 homes, and with rare exceptions met with interested listeners. The result of their efforts is that more than 2,800 homes, besides regular boarding houses, were opened to visitors, and quarters for more than 10,000 people have been provided outside of the hotels. The information was tabulated in such a way that it was but the work of a few seconds to refer an applicant to half a dozen names in any desired neighborhood and at any price. In the hands of Chairman S. C. Dobbs and Secretary G. M. Chapin this information bureau has given invaluable service.

The public safety committee has had in charge the protection both of the citizens and of their guests from the professional pickpockets and criminals who are always attracted to such gatherings. Naturally, the work of this committee cannot be made public, but its efficiency has already been made plain. This committee consists of John E. Murphy, chairman; Carlos Mason, J. L. Barnes and John J. Woodside.

SOME RANDOM OBSERVATIONS OF ATLANTA'S SHOW

NOT AS RADICAL as many of the more conservative expected is the 1910 crop of new models. Of the cars on exhibition in the Auditorium there is not one case of a maker who exhibited a year ago having made such startling alterations that one cannot recognize his product at a glance. In some cases a new type of motor has been fitted, with the transmission system left unaltered; in others the motor has not been disturbed, but an improved axle has been added; and again, in not a few cases, the lubrication of the motor has been changed or a new carbureter added.

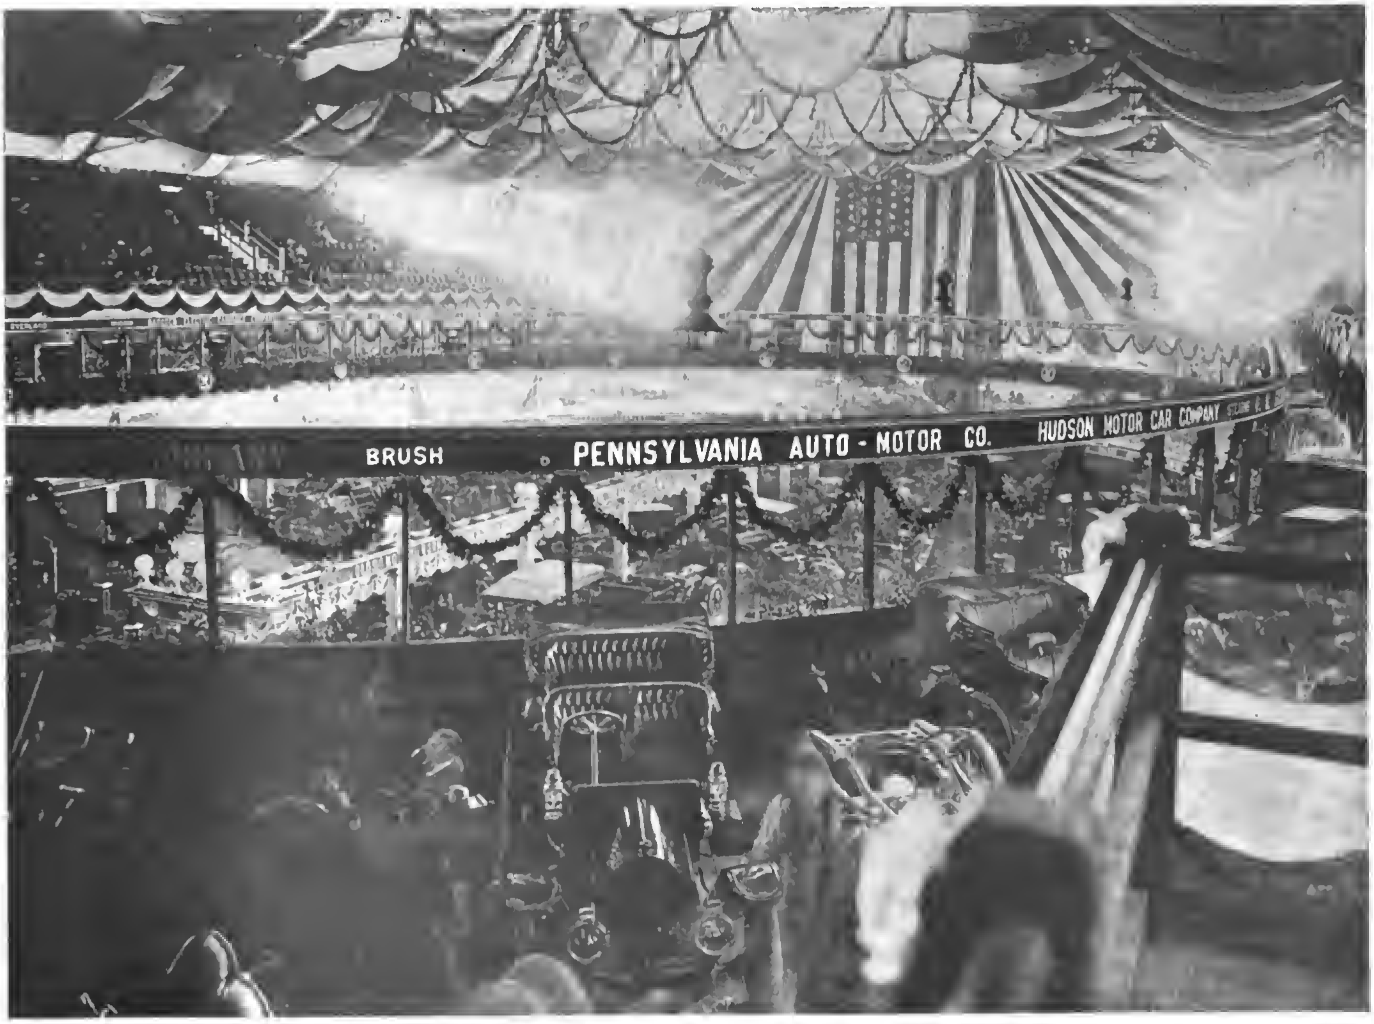
There is very little of the upsetting of old lines and the launching of new ones that was so common a few seasons ago. At that time it was imperative for many makers to turn completely about in order to remain on the market. The trouble with not a few of them was that previously their cars were the conceptions of one individual who refused to change until the salesmen began to resign in despair.

A maker two or three seasons ago deemed it necessary to have something different in order to sell; but to-day a designer or sales manager does not show even the semblance of a blush in acknowledging: "We have not tried to make anything freakish; we have aimed to take what other makers have proved reliable and better it in detail." This is a good indication, for it shows that the makers have confidence in one another, and are willing to admit that the other factory, too, can build cars.

Trustworthy Inferences Possible—In a general résumé of the tendencies as revealed in this show it is well to bear in mind that conclusions from them can be regarded as fairly correct, because nearly all of the old-time makers are on hand. There are 153 cars on exhibition, with three or four exhibits not yet installed. Besides this number of cars with varied types of bodies, two dozen polished chassis are in place. Not so many chassis are shown as will be on hand at Chicago and New York, as such firms as Packard, Pierce, Peerless, Stevens-Duryea and Mitchell are not exhibiting them here, although they have conscientiously displayed them at other national shows. On the other hand, Locomobile shows a highly finished chassis of the shaft-driven model, obtaining a beautiful effect through the combination of polished, painted and brass-finished surfaces. Other spaces showing chassis are those of Stearns, Chalmers-Detroit, Marmon, Winton, Elmore, White, Rambler, Mora, Premier, Oldsmobile, Inter-State, Lambert, Reo, Speedwell, Selden, Standard, Studebaker, Pennsylvania, Hudson, Cole, Carter, Hupmobile and Rapid trucks.

Toy Tonneaus Find Favor—The percentages of bodies favor the present type of five-passenger touring car, but the miniature or toy tonneaus are as prominent now as the roadster types were two years ago. The three-passenger roadster or speed car is not much in evidence, not a dozen of them being shown. This would indicate that the uncomfortable rumble seat has at last fallen from favor. On the other hand, the toy tonneau has progressed and the close-coupled body is growing stronger.

In visiting the many booths it is difficult to name the different types of bodies to suit the several salesmen. In some cases a certain design is designated a close-coupled in one stand and a



From the Mezzanine Floor the View Was Inspiring, a Grand Circle of Signs Encompassing the Whole Auditorium toy tonneau in the next; whereas, a glance shows the tonneau accommodation in each to be two and the rear seat's relation to the rear axle is identical in each. A type of body that is gaining in favor is the four-passenger surrey, this being but a tonneau without doors and with a lower back and sides.

This makes a light type of car, with good seating space.

Tops are generally shown, more than heretofore, and windshields are being made a standard part of the equipment more than heretofore. Not a few makers are adding their own type of windshield, and others have arranged with a windshield maker to build a special type for them best suited to the car's design.

The equipment story might be carried to the lamp, horn, and gas tank realm, all of which are now stock on many cars which heretofore charged extra for them. The double gas headlights are being added in many cases. Stearns is attracting attention because it fits as stock Continental demountable rims. This marks a new epoch in equipment, although some cars, notably the Knox, have been equipping Fisk demountables this year as

"Atlanta at the Wheel This Week!"
—From the "Atlanta Constitution."

stock. Shock absorbers are being furnished on many of the highest prices machines, and one maker, Winton, has added an absorber of home design and make. This action suggests a new angle in the line of equipment.

Improvements in Running Gears—In analyzing the chassis, the running gears naturally present themselves first. For next year frames are invariably heavier; by this is meant that the channel steel side members are made with a greater vertical depth, the channel lips are wider, and not infrequently the stock is 1-32 heavier. A commendable change is the increase in the size of gusset plates at the angle where cross pieces unite with the side members of the frame. These gusset braces are generally stamped integrally with the cross piece and are large, offering real strength.

The dropped frame is now general. Three years ago when Peerless showed this type of frame little imitation was indulged in, but last year it got good assistance and this year has witnessed a veritable landslide to it; so great in fact, that now the cheapest price model has it, and any new car must perforce adopt it. The drop is invariably in advance of the rear axle and varies from two to three inches. Chalmers and the Stearns 15-30 have adopted the double drop, the Stearns having brought out this with the advent of the small car a year ago.

Hand in hand with the drop frame is the three-quarter elliptic rear spring. This type is taking the place of the semi-elliptic type in rear, but it is very noticeable that those makers who have used the platform type for several years are slow in changing, so that the prestige of the platform is equally as strong as it was a year ago. Peerless, Stevens-Duryea on its six-cylinder model, Mitchel also on its six, Mora, Ohio, Standard, Studebaker-Garford, and the National six are a few examples of the use of the platform spring.

Compared with these, however, is a long line of three-quarter devotees, including Pierce, Stoddard, Oldsmobile, Premier, Reo, Inter-State, Pennsylvania, Hudson, Stearns, Elmore, Chalmers, National four, Matheson, Overland, -F-A-L- Car, Mitchel fours, Maxwell model E, and Stevens-Duryea XX. The Oldsmobile has changed from full elliptic to the three-quarters; Stoddard has changed from the semi-elliptic, and, in fact, the majority of the three-quarter converts move from the semi-elliptic class. Jackson continues to use full elliptics in front and rear, as does the Franklin and Maxwell, Cole, Lambert, Black-Crew, Marion, Reo two-cylinder types, Marmon, Overland, and E.M.F. are examples of the full elliptic type. On the Ford the tranverse spring in front and rear is continued. The Ramblers are fitted with triple action springs in the rear, and the Brush runabout uses the four vertical coal springs, one at each corner, acting as they do in conjunction with shock absorbers.

An Era of Big Wheels—The Oldsmobile "Limited" sets the pace for big wheels, this six-cylinder car carrying 42 by 4½-inch tires in front and rear. Next comes the Pierce 6-66 with 37 by 5-inch tires in front and 38 by 5½-inch in rear. On the 6-48 Pierce 37 by 5-inch sizes are used in rear with the standard 36-inch in front. These constitute the only examples of big tires, but there are scores of examples of other machines that have promoted themselves from the 32 to the 34-inch class; and others advancing from the 34-inch ranks to the 36. This has been a year of large tires, and next year gives promise of eclipsing it.

The motor situation is changing very slowly. In the $2,000 to $3,000 class there has been not a little increasing of the bore and lengthening of the stroke. It is questionable what has prompted this, and it may be that the present classifications of cars for contests by cylinder volume, as decided upon by the Manufacturers' Contest Association, has had not a little to do with this. At least it may be designated a coincidence that so many of the new sizes come closer to this classification limit, but few if any cases are on record where the increase of motor size has promoted the car into a higher class.

Prominence of the Long Stroke—The long stroke is gaining in favor. The new White gasoline car has set the pace in this respect, with its bore of 3 3-4 inches and a 5 1-8-inch stroke. This is in direct accord with European dictates at the present time. Not a few other makers have altered their motors to bring them into the long-stroke category. One example is the Premier, in which the stroke has jumped from 4 1-2 to 5 1-4 inches, with the bore remaining at 4 1-2 inches. In a rather graphic way this has resulted in giving a car which with the longer stroke gives as good service on a 3 1-2 to 1 gear ratio as it used to give on a 4 to 1.

One of the most pronounced motor trends is that toward forming four cylinders in one casting, *en bloc* as the Frenchman calls it. Ford led off with this construction, but now there are seven makers showing it, with a total of 22 cars on exhibition. These include, in addition to the Ford, such names as Chalmers 30, Stearns 15-30, White, Hudson, Lambert, and Black-Crow. All motors of this design bear a striking similarity to one another, because of the lack of intake, exhaust, and water piping. All of them are of the L-type, having both sets of valves on one side, excepting the Chalmers, which has the intakes located in the cylinder heads and opened by a rocker-arm action. The new White encloses both the intake and exhaust manifolds, so that only a single pipe connects from the muffler to the cylinders and but one inlet pipe is seen. Nearly all of these motors use forced water circulation.

Next to the *en bloc* comes the six-cylinder type. It cannot

be argued that the six is losing ground, although its progress is very slow. It has some new supporters this year, although a few of its old-time exponents are not exhibiting their sixes. The Mitchell is a new one, so is the Knox, and to these can be added the Standard. Pierce remains in the six-cylinder field only, building nothing else; Winton is in the same boat with two six types; Stevens-Duryea, one of the "six" pioneers, shows two sixes, one being model AA with 4 1-4 by 4 3-4-inch cylinders. Franklin continues its six-cylinder model, as does Oldsmobile, Premier, Matheson, National, and Pennsylvania. All told, there are 24 six-cylinder models on exhibition, representing 13 different factories.

There have been very few additions to the valve-in-the-head army of builders during the past year. The new Standard six is one example, however, and to this might be added the Mora 20. The new four-cylinder Reo with intake valves in the head and exhaust valves in offset ports must not be overlooked. The valve-in-the-head ranks now include such names as Pope-Hartford, Stoddard-Dayton, Franklin, Chalmers 30, Mitchell, Pennsylvania, Matheson, Great Western, Moon, Jackson and Knox. Of this number but one, the Moon, uses the one rocker arm for the intake and exhaust valve of each cylinder. The Stoddard used to do this, but now has a rocker arm for each intake and also for each exhaust. The Moon and Jackson are examples of carrying the camshaft over the cylinder heads, all of the others locating this shaft within the crankcase.

Unit Construction Now a Question—Closely associated with motor design comes the problem of unit construction, by this being meant either locating the motor and gear box together as one, or a similar arrangement of the gearbox and rear axle. Many builders have concluded that it is best to have but two units in the power and transmission systems. The Stevens-Duryea and Maxwell have been originators in this construction, as well as in three-point support. A count shows that there are 58 cars on the stand employing unit construction of either of these types.

Thermo-syphon cooling of the motors has not progressed as many enthusiasts had reason to expect that it would. It is appropriate that at the first National show in the South the father of thermo-syphon cooling should be on hand, namely, Renault. It is also interesting to see shown for practically the first time the Mora 20, which is a low-priced runabout carrying the same general lines as the Renault and using thermo-syphon water circulation. This new star in the motoring firmament uses a Renault type of hood, and has the radiator located where the dash ordinarily is placed. The two and four-cylinder Maxwell cars all remain firm with thermo-syphoning cooling, as do the Overland, the Jackson and Moline, and one model of Cartercar.

In the field of positive circulation by either a gear or centrifugal pump the latter is claiming more and more attention at the hands of the makers. In some cases this is due to the fact that it is quieter, and in others owing to the lack of gears and the consequent avoiding of gear stripping.

Magnetos Are Universal—The magneto equipment may now be considered practically general, even the $800 car not being complete without it. The dual ignition system is gaining rapidly in popularity, by dual being meant that system with one set of plugs and two current sources, a magneto for general use and a dry or storage battery for starting and emergency purposes. This system is simpler than the complete double outfits.

The ranks of make-and-break ignition have not suffered a change for the better or worse during the year. Locomobile and Premier are the two exponents of this class, although in the Studebaker-Garford the make-and-break spark is created in the magnetic spark plug. This will be the second season for this plug on the Studebaker-Garford.

The Franklin is one example of the single ignition system, these motors having the magneto only, and no storage or dry cells for starting purposes. The Ford flywheel magneto is still in use. A few examples of special systems are the Atwater-Kent, fitted on the Elmore and other cars, and the Delco system shown on the Stoddard and Cadillac. The Delco, generally speaking, resembles the master vibrator system in that for a four-cylinder motor there are four non-vibrating coils with a master vibrator electromagnetically operated. On both the Stoddard and Cadillac the coils with vibrator parts are carried on one of the cylinder castings.

Carburetion for next year is much where it was this year. The automatic carbureter is very general. In the Schebler and Stromberg spring-controlled auxiliary air valves perform this function; in the Kingston, Planhard and others, bell valves are used. The water-jacketing of the mixing chamber has come in for general adoption. Many of the cars fix their own makes of carbureters, notable in this class being Pierce, Peerless, Packard, Pope-Hartford, Locomobile, Studebaker-Garford,

One of the Finely Lighted Galleries Where the Parts and Supply Makers Displayed Their Various Products

Franklin, Stearns, Reo, and others. Pressure feed of gasoline to the carbureter has gained, in a few instances, all of the Stoddard models now carrying the gasoline tank under the rear of the chassis. Nearly all high-priced cars, and many of the cheaper models, have fuel tanks designed to contain a reserve supply of three or five gallons, which can only be drawn upon by turning a special valve.

Circulating Lubrication is Prominent—A review of the new motors would be incomplete without at least passing mention of the lubrication systems. In a word, it is the crankcase contained circulation system which is forging to the front, and now the mechanical oiler mounted on a leg of the crankcase is comparatively rare. The big Stearns has come into line with the circulating system; the Pope-Hartford has installed a combination of this and mechanical system, and so have some others. The oiler on the dash, where it overflowed to the floor boards, is now obsolete. For next year the only indication on the dash of a lubrication system is a bank of two or three sight feeds, and in not a few cases only one. The custom of carrying reserve oil tanks on the chassis is growing. A pump to inject it into the crankcase is used.

Considerable activity has been displayed in the matter of clutches for next season. A notable departure in this line is the introduction of dry disk clutches by the Packard and Stearns companies, the later only in its 30-60 cars. The Stevens-Duryea was the pioneer in the dry disk clutch field, bringing out the multiple disk clutch with leather facing five years ago. The Stevens has continued to use the dry clutch ever since, although the leather has been replaced by thermoid, raybestos, and other wire-asbestos combinations. In the new Packard a comparatively small number of disks is used, and these are faced with wire-asbestos. On the Stearns one set is faced on each side with this material.

The selective gearset has increased in favor during the year. As yet the three-speed set is in the majority, but there is a big array of sets giving four forward variations. In this category are noted Pierce, Peerless, Winton, Locomobile, and some Apperson models. The Maxwell model Q and Hudson are examples of the three-speed selective set entering into the make-up of cars selling at below the $1,000 mark. The planetary is still used on the one and two-cylinder Reos, Ford, Brush, Buick 10's, etc.

There are four or five examples of friction transmission, these including the Lambert, Cartercar, Petrel, Metz, and a part chassis shown by the Acorn Motor Works. The aluminum disk on a continuation of the crankshaft and the fiber-faced wheel on the crosshaft continue to be the conventional friction system.

In final transmission of power to the rear axle the shaft is in the supremacy, There are a few examples of chain, these being the Locomobile 40, some of the Apperson models, Brush runabout, Cartercar, Lambert, Petrel, Metz, and one and two-cylinder Reos. The floating rear axle is also firmly established.

FRENCH CONSTRUCTORS SEE MONEY IN THE AIR

PARIS, Nov. 2—The fact is indisputable that the manufacture of aeroplanes has now become a real industry. Six firms are actively engaged, each one turning out flying machines in regular series. Since he made his flight across the English Channel, Louis Blériot has booked orders for 150 small, one-man aeroplanes and for 12 passenger-carrying machines. By the end of the year he will have sold 200 aeroplanes. At the present moment six completed machines are being turned out per week, and contracts have been booked or are about to be booked which will absorb the output for several months ahead.

Voisin, who has been in the business longer than anybody else, has sold 40 machines during the past year, his total production being about sixty. Henry Farman has sold, or has orders in hand for 40 machines, and Antoinette declares that it has produced or has under construction 60 monoplanes. Bayard-Clément, the well-known automobile constructor, has made arrangements for producing one thousand aeroplanes similar to the one with which Santos-Dumont made his cross-country flights, but equipped with Clément engines. Santos-Dumont will personally supervise the construction. It is not known how many of these machines have been secured by private users and agents, but two hundred will probably be a safe estimate.

The Wright Brothers, who are represented in France by the Société Générale de Navigation Aerienne, do not figure largely on the sales list. As the aeroplane with which Comte de Lambert made his cross-Paris flight is the twelfth of the regular series, the total number given to customers cannot exceed a score. The smallness of the number is not occasioned by lack of orders, but by the initial difficulty in obtaining just the right quality of raw material from America. As this difficulty has now been overcome, construction in large series will commence at once. In view of the flight recently made by Comte de Lambert, it would not be surprising if an important announcement were made shortly regarding the use of Wright machines for military purposes.

French aeroplane builders, like the early automobile manufacturers, have had to make arrangements for training their pupils. Blériot has secured a large stretch of open moorland within three miles of Bordeaux, on which he will establish an aeroplane school before the end of the year. Purchasers of the large machine, selling at $5,200, will be trained free; those securing the small machine at $2,200 can be taught to fly, without being made to pay for smashes, at an inclusive fee of $200.

Antoinette, Farman and Voisin have each established aeronautical schools at Mourmelon, near Rheims, the ground being a magnificent plain, with a surface like an English lawn, loaned to them by the army authorities. Sheds have been erected along the edge of the ground, each one being very completely fitted with power-driven tools, comprising everything necessary for repairing the most serious smash. Henry Farman, unlike the others, has erected his main works on the edge of the aerodrome.

The Société Générale at present trains Wright pupils at Port Aviation, the Juvisy aerodrome to the south of Paris. A larger and more suitable ground exists, however, at Pau, and will be used by Comte de Lambert and Paul Tissandier next year. Bayard-Clément appears to have made no arrangements yet for training clients, but as the first series will not be ready until March there is really no hurry.

In addition to aeroplanes, French constructors are convinced that there is money to be made in aeronautical engines. Thus, with very few exceptions, the automobile firms have devoted themselves to the construction of special light-weight engines. It would be much easier to give the names of those that have not produced an aeronautical engine than to state those that have. The list is sufficient to prove that French constructors are convinced that there is money to be made in the air at no very distant date.

Santos-Dumont's Demoiselle—The October 30 issue of *Omnia* contains detailed drawings of Santos-Dumont's small aeroplane, from which the following figures are taken: width, 18 feet 3-4 inch; length, 20 feet; depth of wings, 6 feet 6 3-4 inches; wings cut out in front 7 feet 4 inches across and 11 3-4 inches deep to give room for propeller; wing tips are 4 feet 6 3-8 inches above ground; wings in middle are 3 feet 11 5-8 inches above ground; supporting surface 108 square feet; motor has two cylinders, horizontal opposed, 5 1-2 inch bore by 4.73 inch stroke, weighing 114.4 pounds complete.

Atlanta's New Track Auspiciously Opened

Grand Stand and Homestretch of the Famous Motordrome Which Was Opened Tuesday With 20,000 People in Attendance

ATLANTA, GA., Nov. 9—Speed in abundance, no serious accidents, and an attendance conservatively estimated at 20,000 made the opening meet of the great two-mile speedway at Hapeville an immense success. Although the 200-mile race was the real event of the day, the spectators took the keenest interest in the mile trials and the two-mile open, in which Strang and his recently imported racing Fiat twice outran Oldfield and the Benz once handled by Hémery. Strang drove his 175-horsepower car around the track at a rate that exceeded 95 miles an hour, and he could not conceal his elation at romping away from the older campaigner.

Christie had some of his usual hard luck. Robertson, who was to have appeared in two events with his 60-horsepower Fiat, broke an oil pipe coming to the start, and was out for the day.

It looked like a runaway for Chevrolet in the 200-mile race; after he once took the lead he held it to the finish. Once Dingley's Chalmers-Detroit did the best pursuing, and then Stillman's Marmon moved up. Unfortunately a dip in the track caused the latter to throw a rim and tire on the 166th mile. His car went into the ditch on the backstretch and turned turtle, but neither he nor his mechanic was hurt. Chevrolet completed the double century in 2:46:48, which is a new record for the distance in competition.

Great interest centered in the mile trials which opened the speedfest. Here the honors went to Strang, driving the Fiat which on Brooklands, with Nazzaro at its wheel, unofficially covered a 2 1-2-mile lap at better than 121 miles an hour. Strang made the mile in 37.71, according to the timing machine, which now works out hundredths of a second. This displaces Oldfield's record on the Indianapolis track of 43.6. Strang's speed in miles per hour figures out at 95.5. Next best was the Benz of Oldfield, covering the distance in 40.13, with a skate to the top of the upper turn banking that made the spectators start apprehensively.

Christie's front-drive monster may have been the fastest craft engaged, but it made a slow performance of only 48.82. Its builder and driver, who had been working on it most of the night, said that a pinion gave way. John Rutherford's 30-60 Stearns was the only stock contender, and its mile in 50.85 was good traveling.

Again in the two-mile free-for-all Strang triumphed, his trip being accomplished in 1:31:63, with Oldfield six seconds in the rear. Aitken with a National six outstripped Christie, who had had trouble in getting away, and his team-mate, Kincaid.

In the stock chassis event of the largest class, two Nationals, in charge of Aitken and Kincaid, ran one-two, with an Apperson in the third place. In the smaller stock class Joe Matson appropriated the honors with a Chalmers-Detroit, with another Chalmers the closest kind of a runner-up and Joe Nelson's Buick a near third. The proverbial blanket could almost have been thrown over the three cars at the finish.

The handicappers were too liberal with the two Marmons in the ten-mile handicap. They made a runaway of the first two places, with Aitken's National third, coming from scratch with an actual time of 9:12:41, a new competition record.

The most spectacular event of the day occurred in the 200-mile, when Chevrolet's Buick caught fire on its eighteenth lap. Harding, the Apperson driver, who was in the press stand, was the first to detect the flames, and shouted a warning. Chevrolet did not hear, and completed another mile before the smoke blew into his face. In the brief stop while extinguishing the blaze Dingley regained the lap which he had lost and took the lead. His triumph was short-lived, however, for Chevrolet started again with more speed than ever, and after passing the Chalmers driver was never headed.

The track, as may be judged by the times made, was in good condition, and showed no sign of the haste with which it has been rushed to completion in the last few months.

ONE-MILE TIME TRIALS—FREE-FOR-ALL

Pos.	Car	H.P.	Driver	Time
1	Fiat	120	Louis Strang	37.71
2	Benz	120	Barney Oldfield	40.13
3	Christie	130	Walter Christie	48.82
4	Stearns	30-60	J. M. Rutherford	50.85

TEN-MILE STOCK CHASSIS (451 to 600 Cubic Inches)

1	National	40	John Aitken	8:27.22
2	National	40	Tom Kincaid	8:27.71
3	Apperson	50	Hugh Harding	8:50.65
4	Renault	45	Charles Basle	Did not
5	Stearns	30-60	John Rutherford	finish
6	Fiat	60	Louis Strang	Dropped out

TEN-MILE STOCK CHASSIS (161 to 230 Cubic Inches)

1	Chalmers-Detroit	30	Joe Matson	9:49.46
2	Chalmers-Detroit	30	William Knipper	9:49.84
3	Buick	18	Joe Nelson	9:50.18
4	White	20	James Rodger	Did not
5	Fuller	22	Louis Schroltzer	finish

TEN-MILE FREE-FOR-ALL—HANDICAP

1	Marmon	35	Harry Stillman..(60 Sec.)	8:54.96
2	Marmon	32	Ray Harroun ...(70 Sec.)	9:05.67
3	National	60	John Aitken....(scratch)	9:12.41
4	National	40	Tom Kincaid ...(25 Sec.)	9:18.25

TWO-MILE FREE-FOR-ALL

1	Fiat	120	Louis Strang	1:31.63
2	Benz	120	Barney Oldfield	1:37.18
3	National	60	John Aitken	1:43.72
4	Christie	130	Walter Christie	1:51.40

TWO-HUNDRED-MILE STOCK CHASSIS (301 to 450 Cubic Inches)

For Coca-Cola Trophy and $600 to Winner; $300 to Second; $150 to Third

1	Buick	30	Louis Chevrolet	2:46:48.47
2	Chalmers-Detroit	30	Bert Dingley	2:53:33.92
3	Chalmers-Detroit	30	L. B. Lorimer	2:55:15.62
4	Renault	45	Charles Basle	3:05:10.31

Note:—Timing of seconds involves hundredths.

Strang the Star on the Second Day

Atlanta, Ga., Nov. 10—Interest to-day centered in the special match race involving Strang, Oldfield and Christie. The big Fiat again defeated the Benz. Strang covered the 10 miles in 7:21.94, which is another competition record, displacing Oldfield's figures of yesterday. Oldfield gradually fell behind as the laps were reeled off, his time being 7:27.71. Even this, however, was better than his record of the day before.

The 10-mile stock chassis brought out George Robertson for the first time during the meet, with his 60-horsepower Fiat, and Strang apeared with its twin brother. Marquis was at the wheel of a 30-60 Stearns and Harding drove an Apperson "Jack Rabbit." Strang led at first, but on the third lap his engine required attention. The other cars quickly passed him, Harding in the lead. Strang finally withdrew, followed by Robertson, and Harding won handily from Marquis by a full minute.

The closest finish of the day took place in the 10-mile amateur free-for-all. John M. Rutherford with a Stearns, William E. Oldknow with a Buick and Calvin Travis with a Chalmers-Detroit were the starters. Rutherford took the lead at the start, closely followed by Oldknow. They set a hot pace, and Travis was soon distanced. Then followed the prettiest race of the meet. Rutherford held the lead until the last lap. Coming down the home stretch Oldknow drew up even with him, and to the spectators it looked like a dead heat. The electrical timing instrument showed that Oldknow was 1-100 of a second, amounting to 17 inches, ahead. For the final event, the four-mile, Strang brought out his big Fiat and again trimmed Christie.

The 100-mile stock chassis race was the hottest kind of a fight between Knipper's Chalmers and Nelson's Buick, until the latter ran out of oil and had to slow down.

TEN-MILE SPECIAL

Pos.	Car	H.P.	Driver	Time
1	Fiat	120	Louis Strang	7:21.94
2	Benz	120	Barney Oldfield	7:27.71
3	Christie	130	Walter Christie	Dropped out

Note:—Strang's time is a new record; average speed per hour 81.46 miles.

TEN-MILE STOCK CHASSIS

1	Apperson	50	Hugh Harding	8:30.68
2	Stearns	60	Louis Marquis	9:30.67
3	Fiat	60	Louis Strang	Dropped out
4	Fiat	60	George Robertson	Dropped out

TEN-MILE FREE-FOR-ALL—AMATEURS

1	Buick	30	William E. Oldknow	8:52.56
2	Stearns	30	John Rutherford	8:52.57

100-MILE STOCK CHASSIS—161-230 IN.

1	Chalmers-Detroit	30	William Knipper	1:40:46.82
2	Chalmers-Detroit	30	Joseph Matson	1:41:52
3	Buick	18	Joe Nelson	1:43:10

SUCCESSFUL RADIAL TOURS TO ATLANTA

Atlanta, Ga., Nov. 9—One hundred and sixty-two cars took part in the five good roads tours which centered in Atlanta today. The starts of the tour were made from Albany, Fitzgerald, Dublin and Savannah on Monday, and from Augusta on Tuesday. The cars from the first-named three cities spent the night at Macon, and picking up additions to their number, pushed on to-day to their destination. The Savannah tourists made their night stop at Milledgeville, where they, too, gained new recruits.

There was much fast driving in the tour, and the highway was marked by disabled cars at more than one point. No serious accidents were reported, however. The survivors checked in at an early hour. In each run there are prizes to be awarded according to Glidden tour rules, and the technical committee still has much work to do before the winners are decided. The prizes total close to $5,000, so competition is keen.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H Beck, Secretary, 216 Odd Fellows Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Autuomobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 21-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 19-26......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show. D. H. Lewis, Manager.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

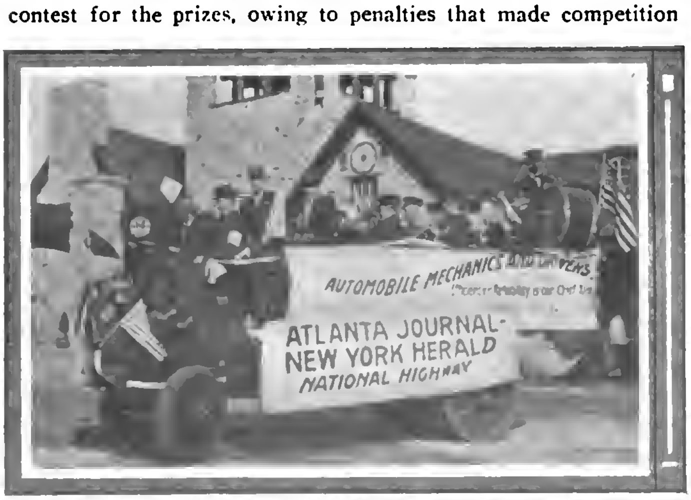
When the Tourists Reached Atlanta a Warm Southern Welcome Awaited Them On All Sides

NEW YORK-ATLANTA TOUR COMES TO TRIUMPHANT END

ATLANTA, GA., Nov. 4—After nine days' running the participants in the New York *Herald*-Atlanta *Journal* good roads tour reached the Gate City of the South, triumphantly ending the marking out of a new national highway. Their course has stretched through nine States, covering 1,063 miles, over roads of every degree, good, bad and indifferent.

The tourists in their progress have rubbed elbows with city and country folk alike, bearing to all their gospel of good roads. Through commercial and industrial centers, over mountain trails and across broad tobacco and cotton fields their way has been a demonstration as well of the necessity of highways as of their possibilities when completed.

Of the 28 clean-score contesting cars which left Commerce, Ga., yesterday morning, 26 finished with their records untouched; of the 38 which left Herald Square a week ago last Monday, 35 reached the final haven. Seven had formally withdrawn from the contest for the prizes, owing to penalties that made competition useless, but their continuance with the tour showed the stuff they were made of. Their passengers won the esteem of all fellow-tourists by their goodfellowship and sportsmanlike behavior in the face of breakdowns and hardships.



The Band That Led the Procession Into the Gate City

Two Eleventh-Hour Delinquents—Jacques Futrelle, who had been handling the steering wheel of his Jackson only two months before he left Boston to participate in the tour, was one of the unfortunates. He bent an axle Tuesday, and after repairing it was forced to send the machine full tilt into the ditch at a sharp turn to avoid ramming a team driven by a dreaming negro. The Maxwell, which had withdrawn from Class 4 several days before, pulled the Jackson out, but in the act broke its own differential. After righting his car, many parts of which were bent and disordered, Mr. Futrelle took the Maxwell in tow as far as Anderson, S. C. Then by an all-night drive he succeeded in reaching Commerce at 5:15 yesterday morning in time for the start for Atlanta.

The two cars withdrawn on the last day's run were the White Star, the only representative of Atlanta's automobile building industry, and the Knox, entered and driven by W. A. Kelly, of New York City, which was reported to have broken its steering gear.

List of Perfect Score Cars—The cars which finished the entire run with perfect scores are as follows:

CLASS 1—Cars Costing $4,001 and Over

Thomas, John J. Woodside, Atlanta, Ga.
Thomas, J. L. Barnes, Atlanta, Ga.
Thomas, C. I. Ryan, Atlanta, Ga.
Renault, Renault Selling Agency, New York City.
Matheson, Matheson Automobile Company, New York City.
Benz, Chamber of Commerce, Atlanta, Ga.
Apperson, Official Automobile Blue Book Publishing Company, New York City.

CLASS 2—Cars Costing $3,001 to $4,000

Franklin, W. C. Cleveland, Greenville, S. C.
White Steamer, W. C. White, New York City.

CLASS 3—Cars Costing $2,001 to $3,000

Premier, City of Charlotte, Charlotte, N. C.
Pennsylvania, Pennsylvania Sales Agency, Atlanta, Ga.
Oldsmobile, E. B. Douglas, Miami, Fla.
Corbin, Chamber of Commerce, Roanoke, Va.
Selden, Evelyn Harris, Atlanta, Ga.

CLASS 4—Cars Costing $1,251 to $2,000

White, Board of Trade, Commerce, Ga.
White, Board of Trade, Moultrie, Ga.
White, Chamber of Commerce, Anderson, S. C.
Buick, Chamber of Commerce, Spartansburg, S. C.
Buick, William Oldknow, Atlanta, Ga.
Maxwell, Maxwell-Briscoe Motor Company, Tarrytown, N. Y.
Chalmers-Detroit, Read Holliday, New York City.

CLASS 5—Cars Costing $851 to $1,250

Maxwell, Automobile and Commercial Association, Charlotte, N.C.
Studebaker, W. J. Stoddard, Atlanta, Ga.
Reo, R. M. Owen & Company, New York City.
Regal, E. D. Crane & Company, Atlanta, Ga.

CLASS 6—Cars Costing $850 or Under

Maxwell, Maxwell-Briscoe Company, Tarrytown, N. Y.

Others who finished the run, although under penalty, were the Studebaker, entered by the Board of Trade of Winston-Salem, N. C., which was delayed two days ago by a broken axle, and the Oldsmobile, driven by Henry J. Lamar, Jr., of Macon, Ga., which was penalized on tbe first day out for delays due to three tire blowouts and a bold-up by a freight train on a grade crossing back in New Jersey.

Story of the Final Day's Run—At Winder, Ga., after a 24-mile run from Commerce, the caravan was held up bodily by the town police force, and compelled to choose between the alternatives of partaking of sandwiches and coffee in the public square or going to the calaboose. Naturally enough, all of the tourists chose the former, although they saw in prospect many other such lunches during the day. Let it not be thought that their detention was on account of breaking the speed limit, for a banner crossing Winder's main street bore the inscription:

"Welcome! Reduce Speed to Sixty-nine Miles per Hour!"

Tbis announcement set the horns to honking and the sirens to screaming, but the invitation was not accepted.

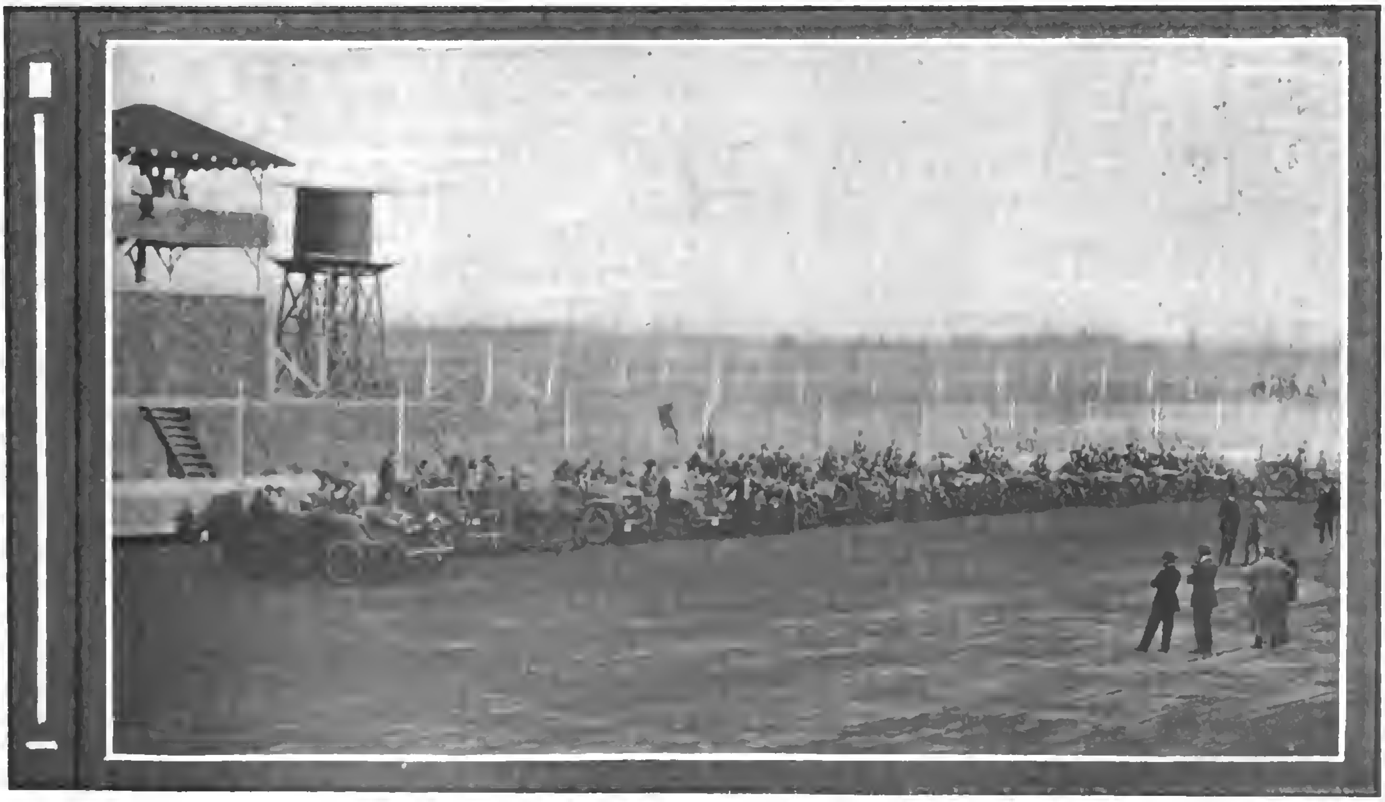
Luncheon at the Club House of the New Motordrome

Near the village of Snellville, 55 miles from Commerce, roadside enthusiasts had menageries of 'possums arranged along the roadside, with welcoming banners and more sandwiches.

All along the line the tourists were bombarded with garlands of flowers and fleecy bolls of cotton, until they looked like so many Santa Clauses. And that, too, with cotton selling at 15 cents a pound!

Near Snellville the Benz car, driven by Ernest Stoecker, who had handled its wheel in races, broke a front spring. It took just 25 minutes for Stoecker and Count W. von Gienauth, his passengers to replace the fractured part, and they rejoined the procession before it reached Decatur, 20 miles away. The Stearns official car snapped one of its rear springs, but with the assistance of a village blacksmith mended it by the insertion of a wooden block.

Mrs. F. D. Hughes, of New York City, suffered the only accident which has occurred to any member of the tour. While cranking her Chalmers-Detroit near Stone Mountain the motor back-fired and broke ber right forearm. Mrs. Hughes was carried to Decatur, 10 miles away, in the tonneau, and had the

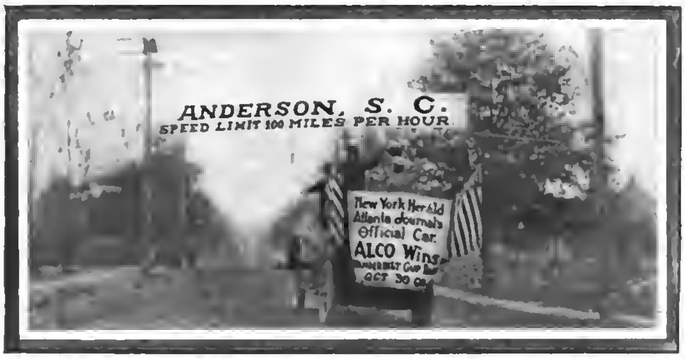


Good Roads Tourists Lined Up On the Broad Expanse of the Homestretch of Atlanta's New Motordrome

School Children at Commerce, Ga., Greet the Cavalcade

bone set. It was an unfortunate ending to the plucky struggle of the Hughes party, which after being put out of the running by the illness of Mr. Hughes a few days ago, still managed to catch up.

Mayor R. F. Maddox, of Atlanta, together with nearly every vehicle in the Southern capital propelled by gasoline power, met the caravan at Decatur. The tourists and their escort formed a procession about five miles long, and swept into the city like a Roman triumph. A hundred thousand persons lined the streets in the business district, overflowing the sidewalks and leaving only a narrow lane, through which the dust-coated tourists passed at a snail's pace. Finally the column was headed for the Piedmont Driving Club, where luncheon was served on the terraces flanking the clubhouse. When the parties returned to their hotels the New York-Atlanta tour had passed into history.



There Was Practically No Speed Limit in This City

PRIZES FOR 26 WINNERS IN TOUR

ATLANTA, GA., Nov. 5—The awards of trophies for the Good Roads Tour over the new national highway from New York to Atlanta were finally decided at a meeting of the judges held this morning in the Piedmont Hotel. Twenty-six cups were awarded to those who finished with perfect scores. The prize fund amounted to $1,700, and was divided as follows:

Class 1—Seven perfect scores; $301 to the class, $43 to each perfect score.

Class 2—Two perfect scores; $300 to the class, $150 to each perfect score.

Class 3—Five perfect scores; $300 to the class, $60 to each perfect score.

Class 4—Seven perfect scores; $301 to the class, $43 to each perfect score.

Class 5—Four perfect scores; $300 to the class, $75 to each perfect score.

Class 6—One perfect score, $198.

Confederate Veterans Welcome Tourists at Decatur

The fortunate ones were those enumerated above as having finished with perfect scores, for Referee Scarritt did not inflict any of the conditional penalties which he has held over the heads of a few drivers whose conduct was not always as considerate as it might have been. The awards, ranging from $43 to $198, in the case of the little $850 Maxwell, will be made in the form of souvenir cups or trophies.

The festivities reached their climax in the banquet to the good roads pilgrims given last night by the Atlanta Reception Committee in the ballroom of the Capital City Club. Two loving cups were presented by the city of Atlanta to the two newspapers which promoted the run, the New York *Herald* and the Atlanta *Journal*. Mayor Robert E. Maddox presented the cup to the Southern member of the newspaper alliance, and it was accepted by James R. Gray, editor and manager of the paper. Ex-Governor Hoke Smith presented the *Herald* cup, which was accepted in behalf of the paper by Hamilton Peltz. Toasts were drunk by all, amid the cheers of the guests, while the band played "Dixie" and the "Star-Spangled Banner."

"Official Blue Book" Car a Clean Score Survivor

PRECISION IN PARTS PRODUCTION

By Thos. J. Fay

ELKHART, IND., Nov. 8—History, as it relates to the building of automobiles, holds in its maw many half-baked attempts, some flat failures, and much of success. When a car indicates that it is not going to make good history, and it happens to have a few parts (from some outside shop) in its make-up, the parts are condemned as beeing the faulty members, and parts makers are ladened with the odium.

Perhaps the maker of the parts followed directions, made them agreeably to the drawings and of the materials indicated in the various clauses of the automobile maker's specifications. If so, who is to blame? Certainly, the designer should take all the responsibility of failure if the parts made and furnished are as per drawing and up to the requirements as respects materials. There is still another phase of the problem, entirely besides the story of who should shoulder the odium when failure is the reward of lack of quality of material or due to a surfeit of poor designing. If, when parts makers are requested to bid on work, they find that it is a cheap and incompetent product that is wanted, and the skill of the same parts makers is interjected so that the work is moved up to a higher plane, it is assured that the end will be far more satisfactory and the business will grow and prosper. It may take a little tact to successfully interject a discussion of quality, especially when the work is to be done for inexperienced, but ambitious (possibly), makers of automobiles, who may think that anything is good enough to serve the purpose. If tact fails, and it will betimes, is it not then time to respectfully decline to participate in what is sure to be a flat failure?

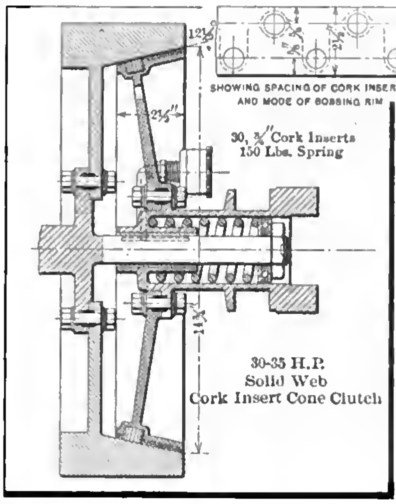


Fig. 1—Cork insert clutch with leather facing, aluminum drum and ball thrust bearing behind spring

Wise Parts Makers Decline to Make Poor Units—The makers of parts are fast learning the futility of doing inferior work, and many of them flatly decline to deviate from what they have learned by sad experience to be a safe course. It is all very well for some company to say (in advertising): "We are building 1,000,000 automobiles of the $5,000 class to sell at $300." If it can be done, the sooner some clever concern accomplishes the task the better for the ultimate consumer. If it cannot be done, then the question is, will it pay parts makers to reduce quality below the point of safety to help "put over" a projeect which is deceptive?

The class of parts makers who expect to survive say no, absolutely no!

In all fairness, it is difficult to discover any experienced concern at the present time which will lend itself to any such undertaking, and it is now the settled policy of the parts makers of acumen to keep well away from the class of work the nature of which will not survive a critical inspection and a road test.

Concrete Illustrations Will Tell the Story Best—Let us sojourn into a shop, examine the product, and learn in so far as experience and a close examination will serve the end, what is a reasonable expectation; for the purpose the product of the General Manufacturing Company, at Elkhart, Ind., will be illustrated and deescribed. This concern makes transmissions, clutches, and such other parts as would seem to be in strong demand, having for customers companies who assemble cars.

Cone Clutches Are in Brisk Demand—Despite the wide variety of multiple disc and other forms of clutches which found favor in automobile designing in recent times, there is still a vast liking for the more simple form of cone clutch, especially in view of the utility of cork, in "insert" form, in conjunction with leather, for the facing. Fig. 3 is of this type of clutch as produced by the General Manufacturing Company, under license from the National Brake and Clutch Company. This clutch is rated at 50 horsepower, and the line comprises sizes from 20 horsepower up. It is claimed for this type of clutch that it will not slip, even if oiled, and will not act "fierce" in starting. Then, it is of great advantage to know that the leather facing will not heat and char, which the cork prevents.

In the absence of the cork inserts it is necessary to place springs behind the leather facing, which is done in the manner as shown in Fig. 4, there being six of these springs evenly disposed around the periphery of the clutch. Among the mechanical features of note, the double universal joint J J, with a slip-member, S, between, offers a means of eliminating the ills of road inequalities to a marked degree. The clutch spring S1 is under and concentric with a shell, and the pressure is sustained by a thrust ball bearing, B.

The spider is of aluminum of a suitable grade, taking into account the character of the work, which included centrifugal forces as well as thrusts, compression and angular distortions. In machining, it is appreciated that the clutching members must engage with precision, and care is exercised to have them meet fair, hold to concentric relations and assemble to a nicety.

Mechanical Differences Are Manifold—Without attempting to depict within the confined limits of this article even a small measure of the deviations in mechanical details which attend the designing of clutches, it may be advantageous to show something of the possibilities. Fig. 5, for illustration, represents an important difference, since the pressure on the spring S may be increased or reduced by screwing up on the cap screw C, which is threaded into the shank of the shaft S1, and the ball thrust B served

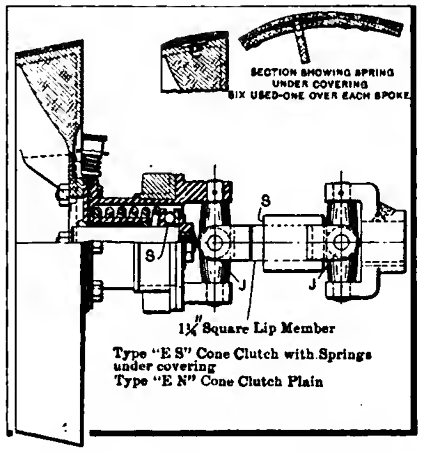

Fig. 2—Cone clutch using springs under the leather facing to assure contact, and defeat fierceness and charring of the leather

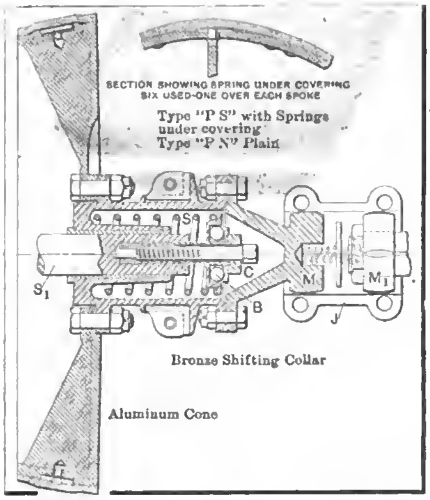

Fig. 3—Leather-faced clutch with means for adjusting the pressure of the spring at will

to sustain the reactive pressure.

The universal joint J, back of the clutch, consists of a housing with a broached (square) hole, and the male members, M and M1, engaging. The spring S2 serves to keep the members M and M1 separated, and in assembling the power plant into the chassis the joint, so made, offers sufficient end-play to enable the units to be lifted out.

The clutch as shown, including all its detail, represents stability, and the cost of the finished product is well within range, even considering cars which sport a modest price tag. What the situation portrays is that it is not necessary to reduce quality below a certain deserving level, and a little ingenuity, properly enlarged upon will generally suffice for the purpose.

As an illustration of the class of work done, referring specifically to transmission gears, reference may be had to Fig. 1, of the Model M system, giving three speeds and reverse, selective. Attention is directed to the short, large diameter main and lay shafts, rolling on Hess-Bright ball bearings of the annular type, in housings of bronze, with closures, thus eliminating the silt of the road and rendering lubrication as a normal expectation.

In this transmission the high speed is "direct," and a roller bearing, R, is placed at the telescope joint of the main shaft and its extension. In going into direct on the high gear, engagement of a pinion, P, with an internal gear. It has the virtue of rendering the shift easy and noiseless, while the work falls on many teeth, instead of (in some examples) four jaws. The extension shaft rolls on two sets of ball bearings, B B, so far apart that displacement is quite out of the question, and the universal joints, when they are to be adjusted into place, may be forced up on the taper ends of the shaft at T and the extension at T1.

The mountings of the bearings, while they are anything but costly, conform to accepted practice, in that the inner race is locked and the outer race is free to slide in the axial plane, being a "sucking fit," however. As an example of this, refer to the two bearings on the extension shaft, and observe that a sleeve, S, serves as a spacer between them, and pressure induced by a threaded member, N, is assured, due to reaction of the shoulder S1.

The selective means is so contrived as to manipulate the racks R2 and R3, and they, being of good diameter, sliding in liberally proportoned phosphor bronze bearings, stand up to the work, sliding freely because they do not deform. The case is of aluminum of suitable thickness, noise considered, and is machined so accurately that it is grease-tight, while ribs are placed at points service, pinch the bearings, and render the case leaky. Careful design makes highly practical the use of this material.

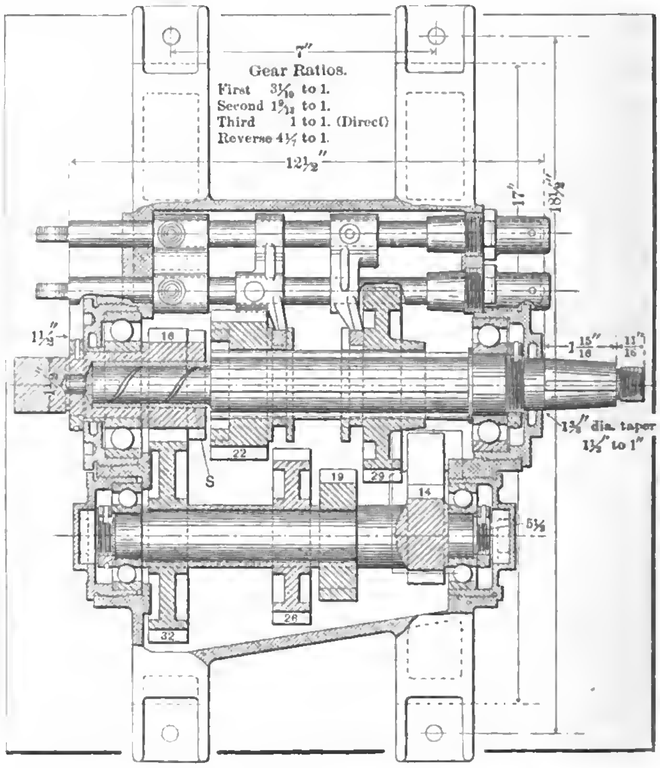

Fig. 5—A modification of the Model M idea, differing in details, among which is the telescope joint bearing

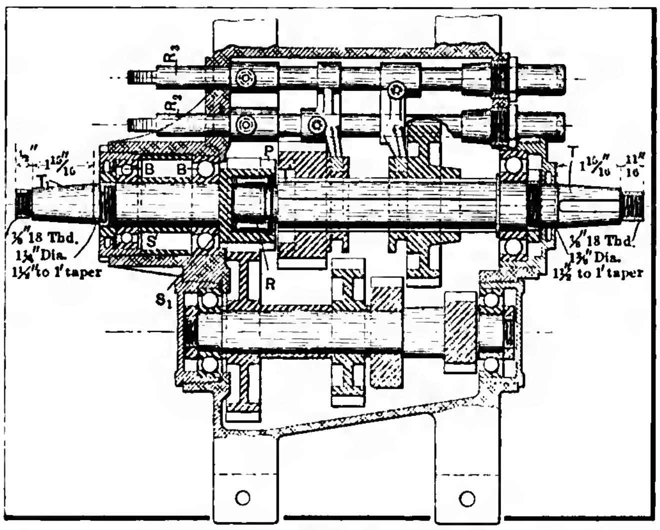

Fig. 4—Model M three speed selective transmission gear with silico-manganese gears and shafts

In this type of gear the ratios of reductions of speeds are as follows:

Direct on high	1 : 1
Hill climbing	1 9-13 : 1
Low	3 1-10 : 1
Reverse	4 1-7 : 1

When Cost Must Be Reduced—With a view to showing how cost can be reduced without eliminating quality, Fig. 2 is offered, and in this example the materials used are the same in every particular, excepting that the roller bearing at the telescope joint is displaced and a bronze sleeve, S, is substituted. The sleeve is long, made of a fine grade of bearing bronze, and is properly fitted into place. This telescope joint is used on many cars of proven quality, and some makers prefer it to ball or roller bearings for this duty. It is less expensive to make, works very well indeed, and in the absence of any diminution in quality of material or workmanship, a difference of opinion is legitimate.

In this example the gear ratios are the same as in Fig. 1, and experience has shown that it is a good disposition of this important phase of the problem. The gears in this, as well as in the example Fig. 1, are of heat-treated silico-manganese steel, and, besides great hardness, kinetic ability is a marked quality. It has been proven, time after time, that teeth of gears made of this material, if they are properly hardened, are not only "file hard," but they may be deformed by exerting great pressure in a testing machine without showing signs of fracture. The "test" fracture is that of a fine grade of material, of great reliability under shock conditions, and shafts of the same material seem to complete the undertaking from a quality point of view.

In the plant of the General Manufacturing Company, pyrometers, annealing equipment, methods of cementing and means for quenching are available, and uniformity is one of the necessities that the company recognizes. In the process of manufacture, hobbing machines, gear-cutters and other equipment of the latest and most available form are used, and additions are being made as rapidly as the situation would seem to warrant. Testing equipment and metbods of inspection are all that good practice demands, it having been found that when the work is well executed, filing and fitting are eliminated and cost is reduced in proportion, so that costly machines which induce interchangeability soon pay for the excess initial cost.

CAUSE OF EXPLOSIONS IN GAS GENERATORS

By CHAS. B. HAYWARD

ACETYLENE gas generators, to give tbe service which may normally be expected from them, must constantly be maintained in good condition. Private owners, as well as professional drivers, have a habit of permitting the generator to go unattended for several days after it has been used. Then, when the generator is opened, it is found to be more or less obstructed with the residue of carbide that bas become caked to the copper, and is accordingly difficult to remove. The first thought of the average man is to take the nearest piece of metal, a file, or a scraper, and set to work to remove the deposit. It is not generally realized that such a proceeding may lead to a serious accident.

The residuum left by the carbide after the generation of acetylene gas attacks tbe copper of the receiver and chemically combines with it, forming a new substance known as acetylid of copper. This is a highly explosive product, which does not require much excitation to set it in action. Several instances are known where simply bending the copper tubing employed to conduct the acetylene gas from the generator to the lamps gave rise to a series of explosions of a startling nature. The whole interior of the tubing was coated with a light, hard film of copper acetylid, and a report was heard every time the tubing was bent.

In tbe case of a generator, striking the deposits with a tool or piece of metal of any kind is apt to explode this deposit, particularly as the residue frequently contains silicious impurities that are hard, and will either spark or generate considerable heat when struck. The violence of the explosion will naturally vary; the worst penalty of carelessness will probably be burnt hands or face. The best protection against this danger is naturally to clean the generator at a sufficiently short interval after using to avoid the hardening of the deposit on tbe copper surface; but when this has already taken place the cleaning sbould either be done with a metal tool under water or a piece of wood.

VENTURI TESTS SHOW WIDE VARIANCE

So many carbureter makers and experimenters bave taken up with the Venturi tube shape for the vaporization chamber, that it will undoubtedly make many sit up and take notice when it is stated that the Venturi tube, *per se,* does not show constancy, its efficiency for hot water measurements (its original use was measuring purposes solely) differing widely with its efficiency on cold water. More than that, the efficiency is a variable quantity, differing for various degrees of heat.

Thus, in a series of tests made at Worcester Polytechnic Institute, and presented in a paper to be given at the annual meeting of the A. S. M. E. in December, this point is brought out very prominently. In the tests, the following test temperatures were used, and from the results obtained at those temperatures a curve of efficiencies was plotted which includes all temperatures possible with water as a medium: 80 deg., 120 deg., 140 deg., and 180 deg.

These figures were approximately .942, .949, .952, and .959, respectively. Although actually the efficiency of the Venturi tube at those temperatures, the writer of the paper in question, Prof. C. M. Allen, designated these quantities as Venturi coefficient. Plotting these, a curve was obtained which was a straight line starting from .927 efficiency at zero degrees and running to .962 at 200 deg.

FRENCH LEADER TURNS TO STEEL

Tbe discussion of some years ago as to the suitability of steel for automobile engine pistons will doubtless be renewed with the announcement that the French leader in small-car construction, Sizaire-Naudin, has adopted this material for all pistons. This use in small cars of modest price is epochal, for if there is any place wbere reliability is desirable, it surely is in the small car. This piston, too, carries but two rings, and has the piston pin fixed by means of a taper wedge driven into the split end of the pin itself. The top of the piston is made concave to secure better combustion effects.

NEW ALUMINUM SOLDER CONTAINS TIN

It is stated in a French contemporary that the best soldering medium for aluminum is an alloy of that metal and tin. The proportions vary according to the extent to which the soldered articles are intended to be worked; 45 parts of tin and 15 of aluminum forming a good solder for such as are to be shaped afterward. A harder solder, but less easily applied with the soldering iron, is prepared by melting 4½ parts of red copper, to which are then added 3½ parts of zinc and 4½ of tin, the heating being continued until a bomogeneous alloy is obtained.

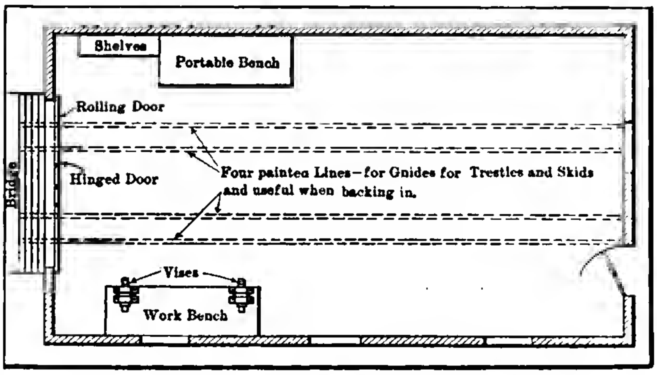
In *The Metal Industry* it is stated that the surface of all aluminum is covered with a thin, invisible coating of aluminum oxide, and that this coating forms instantly after the surface is cleaned; it is very refractory, and is soluble only in hydrofluoric acid. It is necessary, therefore, to remove this coating of oxide simultaneously with the soldering operation, and this is best accomplished mechanically by abrading tbe surface with a steel or brass scratch brush while the solder on the surface is still molten.

FEATURES OF NEW WIRE WHEELS

For the season of 1910, the well-known English firm of wire-wheel builders, Rudge-Whitworth, will produce more wire wbeels than ever before, these having gained much in popularity in the past year, both through excellent service in touring use, and more through tbe stand-up qualities displayed in the races, which have been held. The latest wheels will have a triple row of spokes, the third being set on a long diagonal out to the extreme outer end, so as to lend additional strength to resist the severe side strains. Not that the previous wheels, which will still be continued, lacked in this particular, but that the public doubts on this score, and must be reassured. So wide spread has been this demand, that the makers are now forced to make no less than nine different models, to fit the various car designs, and differing bearings used. The new triple spoke lends itself well to more advanced steering-gear design.

Two Examples of Stone Construction, One, Rubble Stone Laid in Concrete, the Other, Field Stone Laid as Broken Ashlar

NOT once, but several times, has the matter of individuality been commented upon in the course of this story. An example will be given to show to what an extent this enters into the final form of the motor house. The house to be described was built by a man who was something of a mechanic, in that he worked on his car early and late, not because it was necessary, but from preference.



Floor Plan of Garage Possessing an Unusual Pit Idea

This mechanical inclination caused him to plan and build his garage with that idea very prominently in view. So that, although, as described, it sounds like a very funny arrangement, it nevertheless is a very handy one for this particular man. The garage, as shown in the floor plant, is rather large for a single car; in fact, it is plenty large enough to house four cars without crowding. The shape is rectangular, with the door at one end. This is a double door, with a third additional hinged part.

The other end carries a small door for personal use, this being near the house. Besides this, there is a large window. The two sides each carry three good-sized windows, so that the interior is well supplied with light. Near the front end, where most of the work is done, there are: a large work bench, carrying two vises; a portable bench, which may be used to hold parts when taking the car apart and a set of shelves. These are conveniently placed on the two slides, so as to make the most of the available space, the stationary bench and vises being on the left.

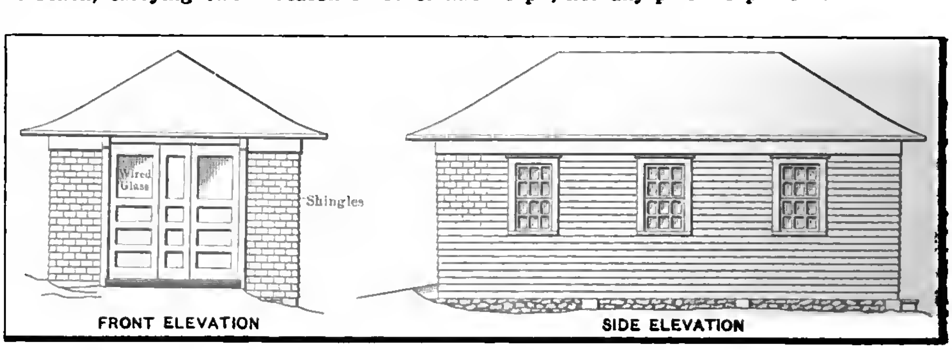
By far the funniest part of it, in matter of fact, the only out-of-the-way part is that of the pit arrangement. The house as built did not have a cement floor, but being located some distance from a city, a pit was an absolute necessity, the latter being realized more particularly after the house had been built. So, a pair of comparatively small and light horses were built, or more correctly, a pair of trestles. These were 31 inches high and built strongly enough to support a car, the length being just sufficient to care for the whole length of the car.

Some Details of Automobile Trestle—Of course this was flat on top so that the car would stand on it of itself. So some method of getting the car up onto the top was necessary. For this purpose another short, inclined pair of trestles were built. Then to get the car onto the "pit," the two sets of flat topped trestles were dragged out into the center of the floor. Next the two inclined members were set into place in the front, and the car could be driven up onto it.

In this position, it was just high enough to allow one to work under it, but since this meant much stooping and looking upward, one of which was hard on the back and the other tiresome to the eyes and neck, the owner built a sort of reclining chair. This he used as a seat, pulling it under the part of the car upon which he wanted to do some work, or removing it when there was no necessity for it. The back of this was adjustable for any inclination, which was very handy at times, and being simple, could be altered very quickly, to suit the needs of the occasion. It is shown in detail on the next page.

When there was no work to be done upon the car the four trestles and the seat were set aside in a corner or elsewhere, the size of the house allowing lots of room for it. In this way the whole floor was kept solid, without any holes to be avoided and counted upon at all times. In addition, it left the whole floor for maneuvering space, and cost very little. Being practically indestructible, the whole outfit could be carried outside if at any time it was desirable or advisable to use the whole interior for cars, as in the case of several visiting cars.

Thus a single instance suffices to show that the man of ingenuity is never stumped. This method would be applicable to a made-over barn or other similar structure, which for some reason or other had no pit, nor any place to put one.

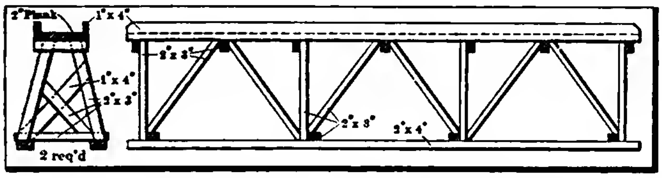


End and Side Elevations of the Same Garage, a Home-Built Affair

In an earlier number of this story the various divisions of the materials of construction were given as:

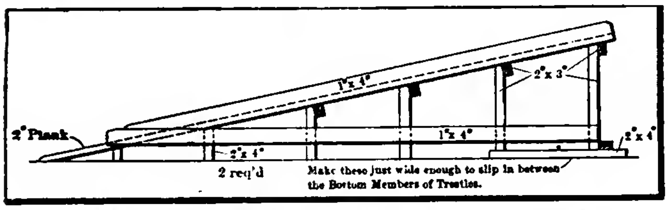
1. Wood.
2. Wood and steel in combination.
3. Steel alone.
4. Concrete.
5. Hollow tile.
6. Other forms of fireproof construction.
7. Concrete in combination with any or all of the others.
8. Brick or stone.

Of these the first has been rather well covered thus far, with the possible exception of the portable garage. This may assume many forms, but the more usual one is that shown in two views at the conclusion of the last chapter, namely, an all-wood structure built either on the panel system, or "knocked down."



Trestle with Flat Top Which Served as a Pit

The more usual is the latter, although the former has much to commend it, being just as cheap to the manufacturers and of much easier erection to the buyer, who usually is a man of very little skill, at least in that particular line.

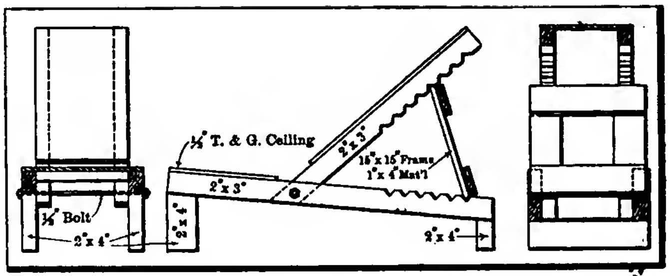


Sloping Trestle Used to Get the Car Up Off Floor

Features of the Portable Form—Elsewhere on this page will be found several views of one of the portable garages now on the market. The plan shows that it is about 13 feet wide by 19 feet long inside. Of this, however, not all is available, some room being taken up by a large workbench, a cupboard and other conveniences. These cut the available floor space to about 12 feet by 16 feet, which is very close to the size arrived at in the previous consideration of the least size that would accommodate a single car with any kind of comfort.

There is a double door at the front, measuring 8 feet in width by 8 feet 6 inches in height. The latter is made large to allow of the car entering with the top up, as it is a very disagreeable feature to have to get out in the rain to fold the top back in order to be able to drive the car in. In addition, there is a small narrow side door for the owner's personal use.

Two windows on each side, with two smaller ones at the back furnish plenty of light, the back windows being grouped over the work bench. The foundation is more in the nature of a suggestion than a necessity. This is not furnished by the makers of the garage, the plan being given to enable the prospective buyer to provide a concrete or stone foundation if he so de-



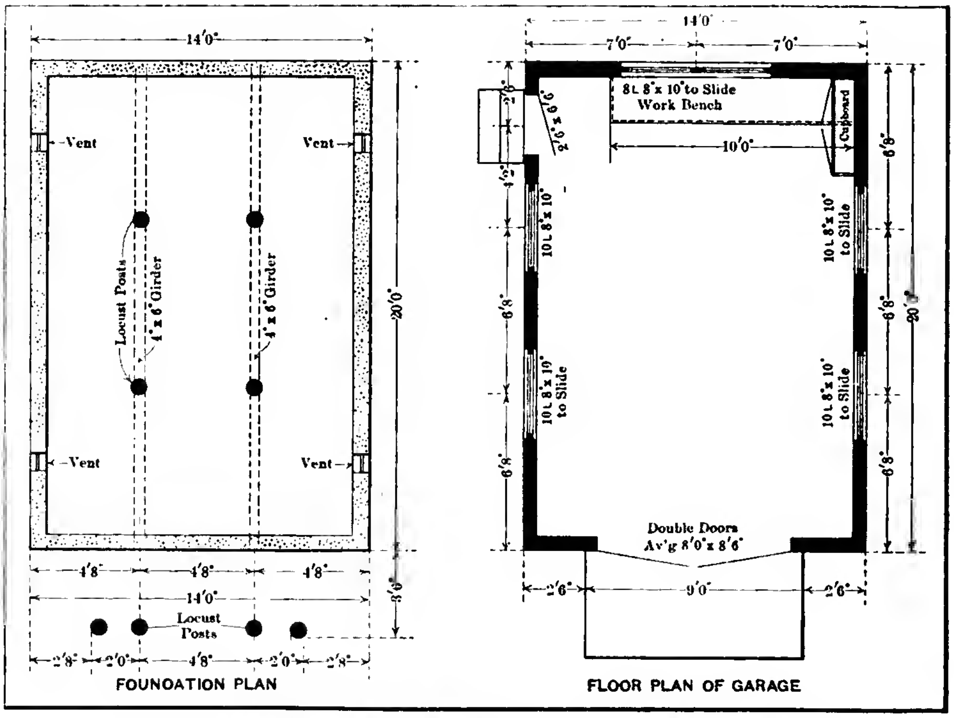
Home-Made Morris Chair to Eliminate Backaches

sires. The locust posts, indicated by the round black spots, are furnished, these being 3 feet 6 inches long. Four of these are in front, and are for the support of the inclined platform or runway to be built there. The other four located in the middle are real foundation posts, in addition to which there are two more to form a foundation for a platform leading to the side door, these not being shown.

When foundations are laid a single width of brick, that is 8 inches, is recommended, or this same width in cement or concrete. A description of some of the other features may be of sufficient interest to warrant the space, so will be given.

Portable Building Details—The structure is designed with two lines of girders, giving a double support directly under the car. All exposed framing material is dressed lumber, while the walls and roof framing are well braced. The roof is sheeted over with a sheating of surfaced boards laid tight. Over this shingles are laid, making a simple but good roof sure to be waterproof. Slate, tin, steel, or any roof composition may be had if desired, but not being regular, cost more. The cost of this house, as shown in the two plans, elevations, and exterior and interior views of last week, is roughly between $175 and $185 at the manufacturer's factory. This with the freight and charges for erection bring the whole cost up to about $225, which makes a very serviceable garage at low cost.

Another illustration shows a frame garage in process of construction. This as may readily be seen is just large enough for one car, has a single door at the front, this being of the double hinged type. Then there are two windows on each side and one at the rear end. The door size is 8 feet wide by 8 feet 6 inches high. The actual inside space in the clear is 12 feet by 17 feet 6 inches.



Floor and Foundation Plans of Small One-Car Wooden Portable Garage

One-Car Frame Garage in Process of Construction

It was built on contract, just as shown, on the outskirts of Yonkers, just beyond the city line of New York, by a carpenter for $350 finished. Considering the geographic location the contract price seems very modest.

Besides the features just described, the floor is of Southern yellow pine, while the roof, contrary to the usual custom, is covered with steel. The picture would seem to show that this was shingled, but that is the shape in which the steel came, that is, in imitation of shingles.

An inspection will show that the owner missed an excellent opportunity to have a first-class pit made very cheaply, as the condition of the ground upon which it is built (the side and top of a hill) make a natural pit. That is, by making a middle section of the floor hinged or loose and laying a second floor on the surface of the ground, a pit would be complete. To use this it would only be necessary to lift up the floor boards then walk around outside and down the hill, laying down on the false floor there, or if the character of the work permitted it, standing up there.

Not Very Much Steel Used—Very little steel is used for garage construction, the usual use of this being restricted to the roofs as above, to the steel framework of concrete and cement places and other similar uses. There is, however, a firm now making and selling a small garage of the so-called portable type, which is entirely of steel. The meritorious feature of this construction is that the structure may be very close to the car size, since the walls are very thin, and secondary, or rather primarily, it is fireproof.

As far as erection is concerned the house comes to the buyer in about the same condition as does the all-frame building, that is, partly but not wholly "knocked down." In the case of the former—the steel garage—the erection needs no tools, since the wrenches from the car's tool kit are about all that could be used. The corners are formed of very light-section structural iron, angles being used. To these walls of sheet iron are bolted. The roof construction is the same, while a sheet-iron door swings from an angle iron frame work. The roof "boards" are also sheet iron. With a concrete floor, which every garage should have anywhere, this building erected is as near fireproof as it is possible to make it.

Since small angles are not expensive, and sheet iron is cheap, this form has many things to commend about it. With an exterior gasoline tank—the only proper form—the whole outfit would be so secure from the possible inroads of fire that the owner of one of these would be foolish to carry any insurance, at least he would if he kept the car in his own garage.

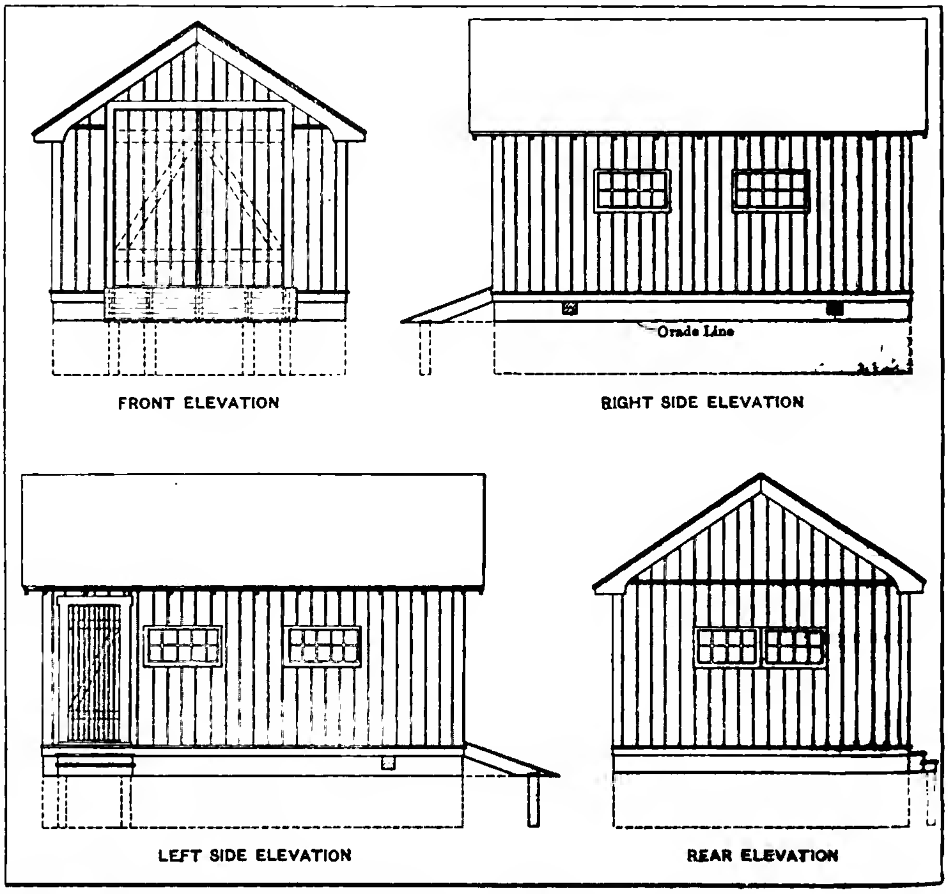
In the all-concrete garage much steel is used, first for the added strength which it gives and second for wearing parts. The latter may at times be adapted to other forms of construction than concrete and should be used wherever possible. Thus for doors sills, particularly the main door through which the car or cars enter, this is very good. In this position it may set down low so as not to make a ridge or bump for the car to travel over when coming in or going out. Thus located it will wear for years.

Other Things Which Must Be Considered—The material alone is not all that must have intelligent consideration. Among other things there is the matter of paint. A frame house with a good filler and a good coat of paint to start with, as well as another every two years would be all right. But this treatment would not do at all for the steel house, or even for the steel roof to the frame garage. Steel by exposure to the mosture in the atmosphere oxidizes or rots away and to prevent this it must be well covered with paint of weather-resisting qualities.

Not only must it be well covered in the first instance, but it must be kept covered at all times, for while the garage might not work all the day, nor all the year round, the atmosphere is always "on the job" and to prevent its serious inroads the steel should be painted every year at the outside, and in places near the seashore or some large body of water twice a year if possible, or if within the owner's means.

Next in order the small concrete garage will be taken up, discussed and many of the best small types illustrated.

(To be continued)



Four Elevations of Portable Garage Shown on Preceding Page, and Illustrated Last Week

New English Ideas In Automobile Construction

WHILE no patriotic American likes to concede that there is anything in the oft-repeated remark "they do things better over there," meaning on the other side of the ocean, it is a fact, nevertheless, that more new devices are brought out and given an intelligent trial on the other side than in our own country, considered very progressive.

As bearing directly upon this subject and perhaps proving or disproving the same contention, a number of recent new ideas in automobile and kindred construction will be shown and discussed. Some of these possess the merit of much trial and experimentation, while others have not yet suffered a severe test, and are more in the nature of untried inventions, which appear to possess more than average merit. The parts to be discussed are mostly engines, but a few new carbureter ideas are included. All of the devices to be described are of English origin.

Novel Expanding Carbureter—The first to be described is a carbureter called by its inventor, Alexander G. Ionides, the Polyrhoe Expanding Carbureter. This device, shown below and in more detail on the next page, differs from the ordinary fuel vaporizer in that the usual small jet orifices are lacking. In addition to this, the throttle valve, so-called, is automatic in its action, which not only governs the inflow of air, but regulates with absolute certainty the flow of gasoline as well.

To describe it more in detail, there is a float chamber, circular in section, containing a float of the conventional type, but working directly upon the needle valve seat through its lightness, and consequent position in the fluid only. That is to say, there are no levers or springs in the needle valve arrangement.

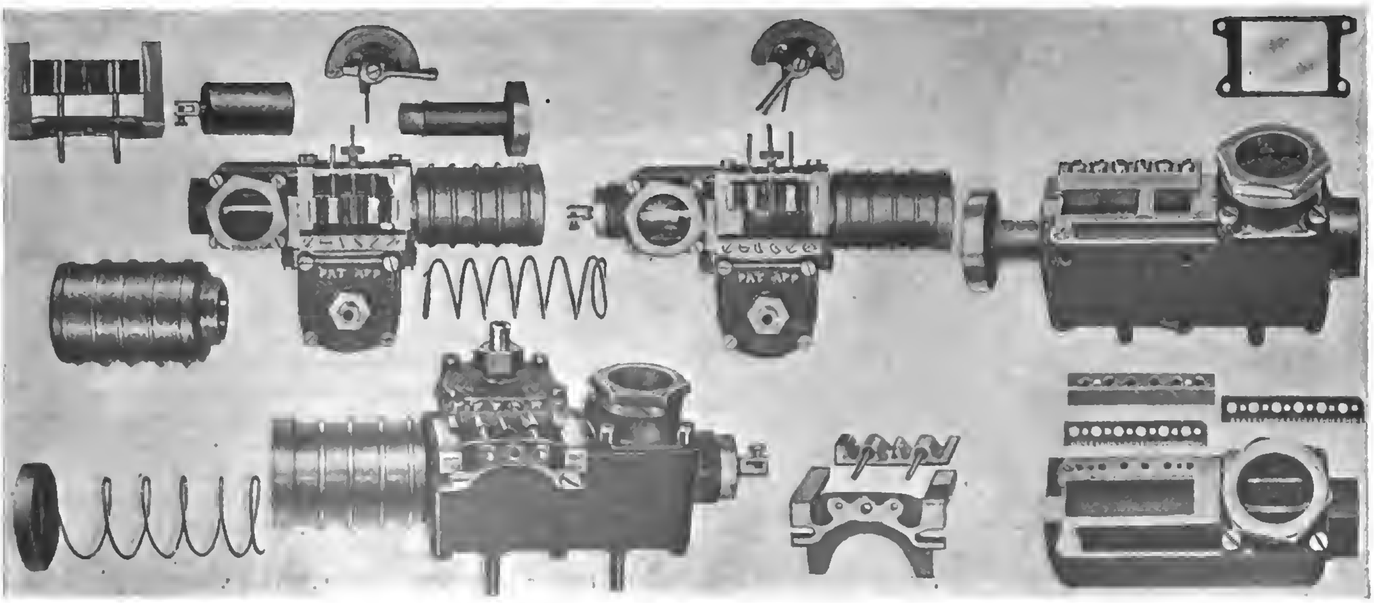
Leading from the float chamber to the jet plates—for plates are used instead of needles—there is a long and very narrow slot, which replaces the usual round hole. This slot extends upward to the jet plates. The latter are five in number, held in place by means of bolts. In each one of these plates one edge carries a series of square key-hole slots, between each two of which is located a rectangular slot. When set in place the key-hole slot in the first plate is directly below a rectangular slot in the second. This, in turn, is surmounted by the key-hole slot in the third, the rectangular hole in the fourth, and the key-hole slot in the fifth. The width of the slots, that is, along the edge where the gasoline flows through them into the vaporizing chamber, is .016 inch on the smallest size made, and .018 inch on the largest size which has yet been put out.

In this manner, as the enlarged section through the jet plates shows, every other plate has openings which are connected on the inside to the gasoline supply, and on the outside to the vaporizing chamber. More than this, the openings into the latter vary in each row of plates, one set or series being of the first, third and fifth plates, and midway between these are another set or series of slots in the second and fourth plates. These being very small, and, consequently, very close together, what is the equivalent of five very flat and very thin sheets of gasoline are sprayed into the vaporizing chamber.

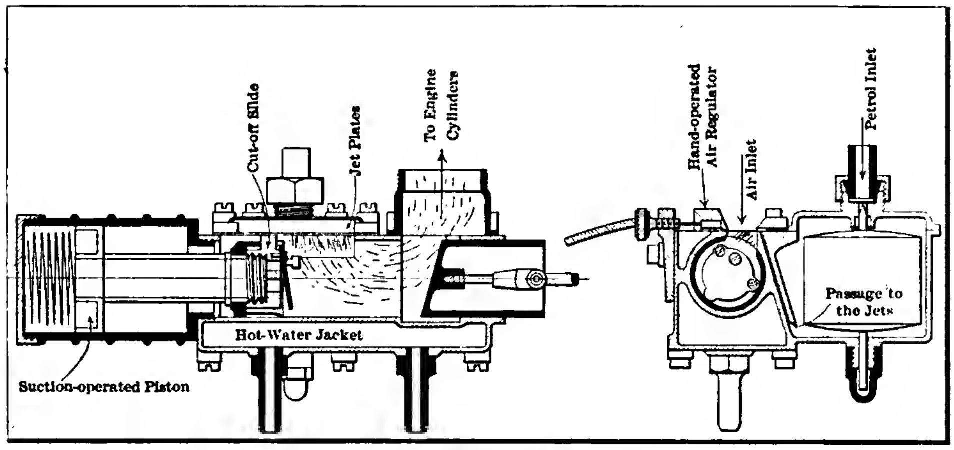
Throttle, Too, Acts Differently—This action just described would be the case, but for the fact that the throttle, of the piston type and working automatically, covers part of these slots. That is, according to the demands of the motor, it either uncovers or covers enough so that the mixture is right. This acts to uncover more and more of the slots through the inductive action of the mixture or the suction of the engine. Opposed to this action is a large diameter coil spring, made of small sized wire, and comparatively weak. Between the motor suction and the strength of the spring there is a constant adaption to the engine requirements. Since the air to vaporize the fuel enters from above the sheet of fuel, the action of the automatic throttle also cuts off the air, at the time it cuts off the gas.

The passage through which the air enters, however, is U-shaped, and may be varied at the will of the driver by means of a sliding member. This is actuated by means of a bowden wire mechanism, the slack being taken up at all times by contrary-acting springs.

In the cut below the large piece in the lower central part is the assembled carbureter. Directly to the left and right, respectively, are the automatic throttle spring and piston, and the air slide. This slide is shown in plain view in the upper left-hand corner, below which is the cover for the piston, or the chamber in which it acts. In the lower right-hand corner is to be seen the body casting, viewed from above, and directly over this a few of the jet plates in actual size compared to the rest of the



Assembled and Partly Disassembled Parts of the Polyrhoe Carbureter, a New English Invention Which Has Proved Its Worth

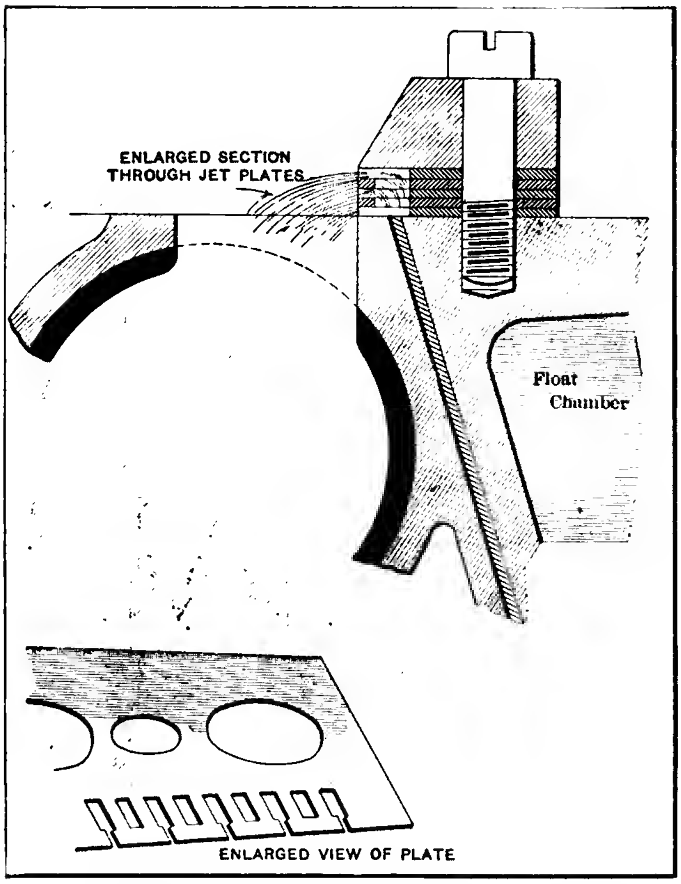


Section Through English Carbureter and End Elevation of Float Chamber

parts. In the upper right-hand corner is the gasoline strainer. The rest of the parts are self explanatory, but it should be remarked right here that several of the parts are shown more than once to make the whole construction clear. As shown this would appear to have many parts, which is just the opposite of the actual case, the parts being few in umber.

The actual throttle, operated by the driver of the car, is also of the piston type, this being set into the other end of the vaporizing chamber, so as to slide across the bottom of the vertical outlet to the engine. The absence of jets of the usual type eliminates the usual accompaniment, flooding. This is particularly noticeable when, running at high speed, the engine is cut off suddenly. This severe test always floods the ordinary carbureter, but this one, never.

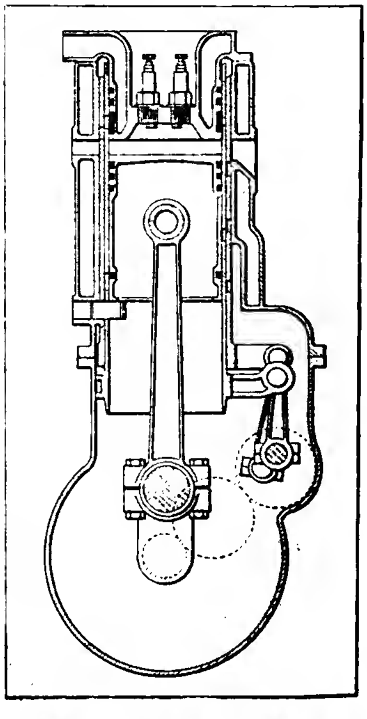
Among other tests to which the new device has been put—for it has been thoroughly tried out—may be mentioned the following: Ten horsepower, two-cylinder Panhard, weighing 2,100, with two passengers and 150 pounds of baggage, averaged 30 miles per gallon; 10 horsepower, one-cylinder Adams averaged 37 miles per gallon; a 10 horsepower, four-cylinder Humber, with two passengers, a top, wind shield, and some baggage, averaged 35 miles per gallon; and an 18 horsepower, two-cylinder Wolseley-Siddeley car with two passengers averaged 26.8 miles per gallon. In addition to these tests, a six-year-old Panhard machine with four cylinders, 80 mm. by 120 mm., was run for a very long time at the exceedingly low speed of 160 to 180 revolutions per minute. This latter was done, too, on a normal, and not a special, adjustment of the carbureter.



Enlarged Section Through Jet Plates and One Plate

Over and above any possible claims, the above actual tests show that the device possesses much merit. This is not to say that no claims are made for it, because the inventor claims that over the whole range of engine speed and power the mixture remains constant and perfect. More than this, he agrees to sell the carbureter on a basis of 19 miles per hour guaranteed, and higher figures if properly paid for. Naturally, in view of these claims, the selling price is rather high, varying from about $33 for the smallest size up to about $45 for the largest. These figures would be net, in England.

Slide Valve Era Is Upon Us—In the past twelvemonth, those who thought that the automobile engine had at last assumed a permanent form have been shown to be in the wrong. Now, just to go to the opposite extreme, following upon the heels of the American, Knight, whose success with the Daimler people has been wonderful, the whole country has gone crazy over this form of engine. Designers are producing all kinds of substitutes for the poppet valve, some good, some bad, and some weird and wonderful, to say the least.



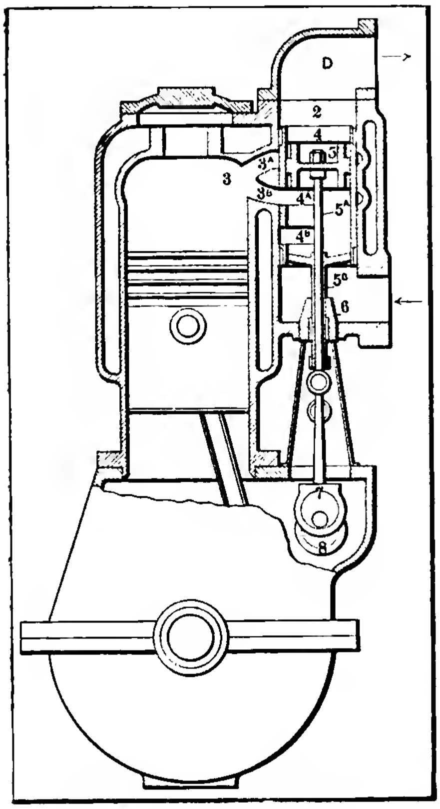
Chalmers-Detroit Slide Valve Engine

Among those which seem to show some merit is the form patented very recently by an American firm, the Chalmers-Detroit Company, Detroit, Mich., shown elsewhere on this page. This would seem to indicate some agreement with Knight, or excellent prospects of making one, for its basic idea is the same as his, and, therefore, covered by his patents, and not workable without a license from him.

In this form an additional slot in the sliding sleeves is introduced, which in combination with extra port openings in the walls and a bypass makes quite a change in the cycle. Through this medium, cool, fresh air is introduced into the base of the engine, where it is slightly compressed as in a two-cycle engine. This slightly compressed air is introduced into the working cylinder twice during each cycle,once during the inflow of the charge and once during the outrush of the heated exhaust gases.

The former adds air to the mixture, and through its own entrance gives an inductive or suction effect to the more pure gas entering in the regular way. Through having the whole suction stroke given up to the inflow of nearly pure gasoline vapor, while the air enters independently, a more even and certainly more thorough, charge is obtained.

Similarly with the exhaust, the air under pressure rushing into the cylinder at about the middle of the exhaust part of the cycle serves to push the rest of the burned charge out quickly, and if it does not clean it out more thoroughly than in the usual case, at least dilutes it to such an extent that any bad effect from its remanence in the cylinder during the gas inflow is completely offset.



Engine With Two Slide Valves, One Within the Other

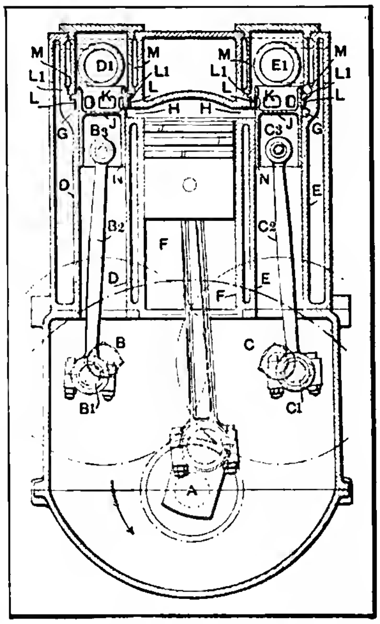
To accentuate the crankcase compression—for that is where the air is compressed—the piston is made very long, while the inner of the two sliding sleeves is carried down further at the bottom than Knight carried his. The head and sleeve construction otherwise is the same as Knight's, at least that is the way the English patent office drawing shows it. Whether this invention will ever be worked on this side is doubtful as this company has no factory over here, so that the first developments probably will appear in the United States.

Piston Valves Supplant Poppets—In the illustration elsewhere on this page is shown an English engine, which has just been brought out, and in which the ordinary poppet valves are replaced by piston valves. These are concentric, one being in the form of a piston, while the other forms a concentric sleeve around it. Both are driven from the camshaft by means of eccentrics and connecting rods, the one for the piston working within the one which operates the sleeve.

In this way the operation of the valve is positive on the down stroke as well as the up stroke, the uncertainty and wavering of the ordinary spring-closed valve being replaced with the absolute certainty of a mechanically closed valve.

As the illustration shows, the cylinder (3) is made with two passages (3a and 3b) to the valve chest (2), within which the valves slide up and down. The sleeve (4) also has two slotted passages (4a and 4b), which are alternately covered and uncovered by the movements of the piston (5). The latter is operated by the rod (5a), while the sleeve is moved by the tubular rod (5b). These slide within the guide (6), and the movement is supplied by the two eccentrics (7 and 8) on the camshaft. Above the valve chest is seen the exhaust pipe (D), while lower down is the inlet opening, not marked with a letter.

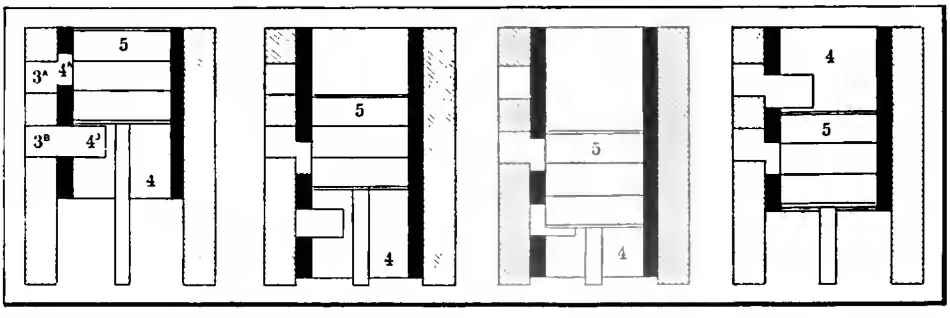
The eccentrics are so set on their shaft that, on the admission stroke, the sleeve (4) travels downwards, the piston (5) meanwhile moving upwards, until the port (4b) registers with the channel (3b). When the main piston reaches to half-stroke on the admission period, the port (4b) is fully exposed to the entire area of the channel (3b), and, subsequently, the sleeve (4), continuing its downward movement, cuts off the admission with swiftness at the outer dead point of the main piston. During the compression stroke, the sleeve (4) is still running down, while the piston (5) is likewise traveling down slowly, thereby covering the port (4a) in the sleeve (4). Upon completion of the compression stroke the center of the piston (5) is opposite to the port (4a), which latter is then almost in alignment with the channel (3b). At this period the port (4b) is right down below both the channels (3a, 3b). In this way the internal pressures are withstood not only by the gas-tight sleeve (4), but also by the wide faced inner piston (5).



Albion Engine Has Slide Valves on Opposite Sides

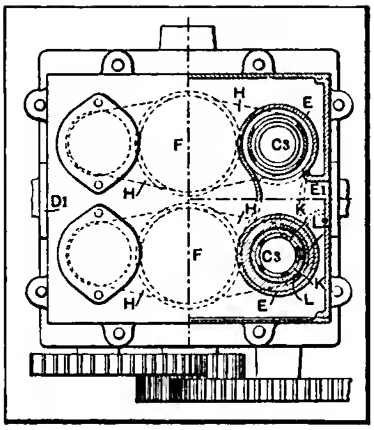
During the combustion stroke the sleeve (4) moves up, the port (4a) thereby ascending towards the channel (3a), while the piston (5) is also moving upwards. When the expansion is nearing its end, both the members (4 and 5) are traveling up, the port (4a) thereby coming fully into line with the channel (3a) when the main piston is approximately at half-stroke in the exhaust period. Gaining speed over the sleeve (4), the piston (5) runs past the port (4a), cutting off the exhaust as the main piston passes its inner dead point. Coincident with this motion, the sleeve (4), having reached its upward limit of travel, comes slowly down, bringing the port (4b) into line with the channel (3b). When the main piston has traveled half its course on the admission stroke, both the channel (3b) and the port (4b) are directly opposite each other, thus affording an inlet orifice of ample proportions. At the termination of the admission stroke the port (4b) in the member (4) runs down swiftly past the channel (3b), thereby cutting off the fuel supply. In order that the operation of the motor may be understood without difficulty, examination of the diagrams reproduced in conjunction with the foregoing information will render its action perfectly plain.

Advantages Are Numerous—Among the advantages which are derived from this construction are that of complete separation of the heated exhaust from the incoming charge by the piston (4), the danger of the one diluting the other being eliminated. Then, too, the design is such that it lends itself readily to



Middle of Admission End of Compression Middle of Expansion Quarter of Exhaust

Slide Valves in Various Positions Throughout the Operation of the Whole Cycle



Albion Engine from Above

water cooling. The valve stems, or what answer to valve stems in the ordinary case, may be lubricated, and are free from the heat of the exhaust. Cylinder pressures and temperatures are withstood better than in the ordinary case, for not only are they received on the outside, but are evenly distributed around the whole circumferential surface by the grooves in the chest. Side thrust is reduced to a minimum and port areas may be accurately proportioned to the desired power or speed.

On the previous page, near enough to the foregoing for comparative purposes, is placed another English piston valve engine. This one has recently been patented by the Albion Motor Car Company, Renfrew, and if reports can be believed, this concern is actively engaged in work on this model of engine, which will soon be placed on the market, as well as being used in the well-known Albion commercial cars.

Slide Valve Displaced by Piston Type on Tee Head Motor—In this engine, the valves are seen to be replaced by pistons, each one displacing one valve. The motor is of the tee head type, so that the change is not as radical as some of the others. The valve, valve lifter and cam mechanism are replaced by the piston valve, eccentric and connecting rod.

The valves are made of a considerable length, so that the opening or passage above is necessarily long, too. This makes the head of the engine very high, and if given over entirely to water jacket, as the patent office drawing shows, would make the engine so cool as to seriously impair the efficiency. This is, however, but a detail of construction.

Within the chest or passage are placed circular orifices (D^1) leading to the exhaust, and (E^1) for the inlet. Communication with these, from the cylinder interior, is effected by means of ports (K) in the valve walls, the same being prevented from ever uncovering the bottom edge of the cylinder wall, by the movement of the eccentric.

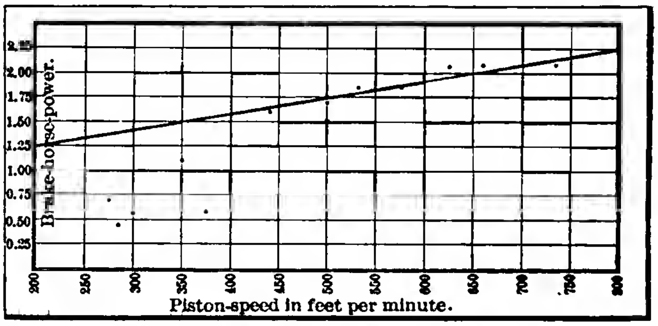
Otherwise the construction is very apparently like any other engine. The elimination of the use of an idler in the camshaft driving gears, however, makes a noteworthy point. As shown elsewhere on the page, this called for unusually large cam gears, and an idler of double width, as the two cam gears overlapped one another slightly.

Object of Variable Stroke Is to Eliminate Transmission—Inventors have worked upon the engine with a variable stroke at various times, and with varying success, most of the engines being little more than schemes on paper. The majority of these, too, sought a more perfect cycle, that is, the object of the variation in the stroke was an improvement in the cycle. Thus, commencing with Atkinson's two attempts in 1885 and 1886, with his Differential and Cycle engines, many attempts have been made. Atkinson's idea, however, was to perfect the cycle, particularly with reference to the length of working stroke and exhaust, while later experimenters followed blindly in his footsteps.

This was not the object sought in the latest English variable stroke motor, illustrated on this page. In this the desideratum was the elimination of the transmission, through the ability of the motor to vary its output from lowest to highest. This variation is effected by having the cylinder offset to a very marked degree and the piston worked through a linkage. This linkage is guided in its movements by another rod. The latter is so constructed as to be movable, this movement altering the length of the stroke, from a very short to an exceedingly long one.

The first figure shows a section through a proposed four-cylinder engine, the one built and successfully tested being but a small single cylinder outfit. In the second figure is the power curve of the "one-lunger" tested, and in the third illustration is to be seen a diagram of the action of stroke variation.

In the latter the letters used are the same as in the first or sectional drawing, A being the real and H the false connecting rod. C is the connecting link and guide, being pivoted to the two connecting rods at B, and movably pivoted at D. F is the double threaded screw through the medium of which the point D is altered, and with it the length of the stroke.

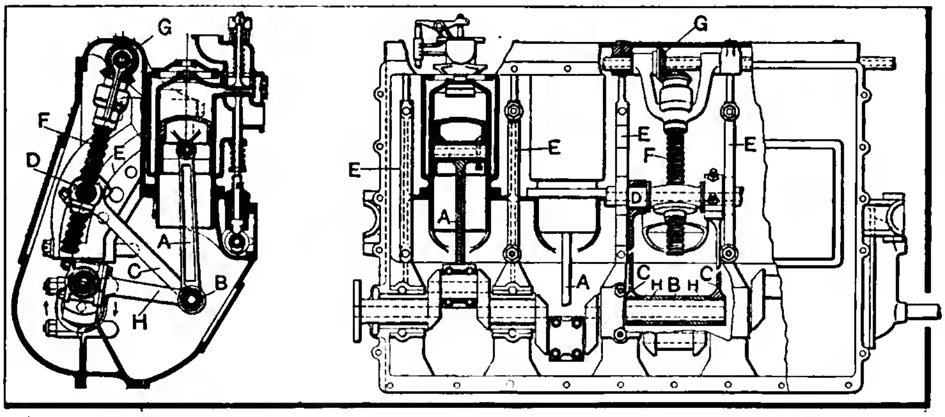


Power Curve of Variable Stroke Engine

This variation is controlled from an overhead shaft, the latter leading back to the dashboard or being actuated through suitable hand or foot levers. Aside from this, the valves, piston and other parts are regular in their construction.

This proposed engine will have four cylinders, nominally of 5-inch bore and 5-inch stroke, the variation in the latter being from a minimum of 2 inches up to a maximum of 7½ inches. This would give a variation in the ratio of bore to stroke of from 1 to .4 up to 1 to 1.5. It is expected that this engine will easily develop 50 horsepower, basing this estimate upon the results obtained in the test with the one cylinder.

Much smaller than this was the experimental engine, which had a bore of but 3 inches and a stroke variable between 1 inch and 3½ inches. This engine would rate by the R. A. C. formula (A. L. A. M.) at 3 horsepower, so that consulting the appended table, the loss due to the added linkages may be seen to be far smaller than one would suppose. That is the question which has held back the progress of this type of engine, the doubt as to the loss which the linkages would entail. In this small, single-cylinder engine, the loss amounted apparently to about 30 per cent, at least that is the amount which the highest power developed lacks of usual output.



Sectional Drawings of Gill-Aveling Variable Stroke Gasoline Engine

Results of Tests With the Experimental Engine

Stroke	Revs. per min.	Piston Velocity Feet per min.	B.H.P.
1 in.	1,700	284	.44
1 in.	1,000	300	.57
1 in.	2,250	375	.58
1½ in.	1,100	275	.7
1½ in.	1,400	350	1.08
1½ in.	2,000	500	1.5
2 in.	1,500	500	1.7
2 in.	1,600	533	1.84
2 in.	2,000	667	2.07
2 in.	2,200	734	2.09
2½ in.	1,050	438	1.6
2½ in.	1,500	625	2.05
3 in.	900	450	1.66
3 in.	1,000	500	1.76
3 in.	1,150	575	1.85
3 in.	1,500	750	2.07
3½ in.	750	437	1.59
3½ in.	850	496	1.74
3½ in.	900	525	1.77

Throughout the tests, the compression pressure was about 85 pounds per square inch for all lengths of piston-stroke, and, although not recorded in the table, we understand that the highest velocity was obtained with a 1¼-inch stroke, when the tachometer indicated 2,400 r.p.m. 320 r.p.m. was the slowest speed at which the engine would run with a 3½-inch stroke, but, with a 1-inch stroke, steady running, at 240 r.p.m., could be maintained. Taking the figures from the third and fourth columns of the table, we have plotted a chart, in which piston-speed in feet-per-minute is represented by the ordinates, and brake-horsepower by the abscissæ; an examination of this chart reveals the interesting fact that the brake-horsepower bears an almost-direct relation to the piston speed, although, for the lower piston-speeds, there is a considerable drop below the arbitrary line of proportion; the decreased efficiency at slow speeds may be attributed to valve leakage, and other causes that are eliminated with increased speed.

Those responsible for the design are J. F. Gill and T. C. Aveling, assisted by A. A. Remington. From the names of the engineers, the new motor is to be known as the Gill-Aveling. Other details than those commented upon are standard, that is, they follow regular automobile engine practice.

While not an epoch-making machine, by any means, the test curves would seem to give hope to the inventors that they are upon the right track, if they have not actually attained what they sought. The loss of power represented in the rather crude first example is not serious, being but 41 per cent. under the formula. This for a single cylinder, which is of notoriously poor balance, is not at all bad, and the outcome of the tests of the four-cylinder power unit will be awaited with much interest.

Rotary Overhead Valves Another Good Idea—The last figure shows another recent English construction, in which overhead valves are resorted to, these being of an unusual kind. The design, for which W. J. Crossley, of Crossley Brothers, Manchester, is responsible, is an exceptionally good one.

An end section and an end elevation are shown, which reveal clearly the valves themselves, and the driving mechanism. There are two separate valves for each cylinder, just like any other engine, but both of these are circular sleeves, rotating within other sleeves. The inner sleeves are driven from a diagonal camshaft at the front end, which in turn is driven from the crankshaft. A worm gear is used to drive the shaft, and the valves, too, are driven by means of another worm gear.

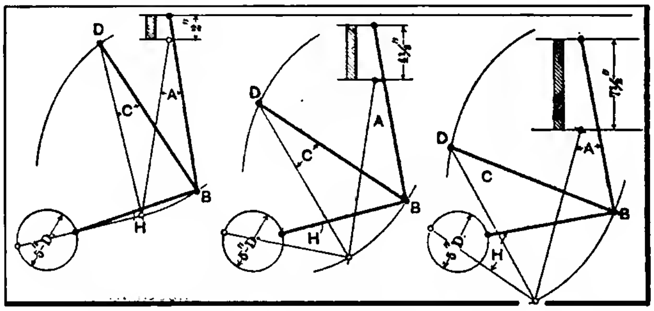
These valves are set at about 30 degrees each side of a vertical, and communicate with the combustion chamber, which is made spherical, through small slots. In addition to the revolution of the inner sleeves by the shaft shown, a similar shaft at the other end of the engine drives in a similar manner the outer sleeve, the rotation of the two being opposite in direction. That is, the inner sleeve on each side of each cylinder rotates opposite to the outer sleeve on each side of each cylinder. It would appear from the description of this engine as if, in multi-cylinder forms, the sleeves along each side of the engine were made and operated as a single unit, the gas having free access to the exterior and interior in a longitudinal direction.

This would mean, in turn, that the inlet valve sleeve acted as an inlet pipe, and the exhaust valve sleeve as an exhaust pipe, so that all piping of this nature would be eliminated. Then the carbureter would be attached directly to the exterior of the inlet valve sleeve. If this is the right idea a very considerable simplification will result a step in the right direction.

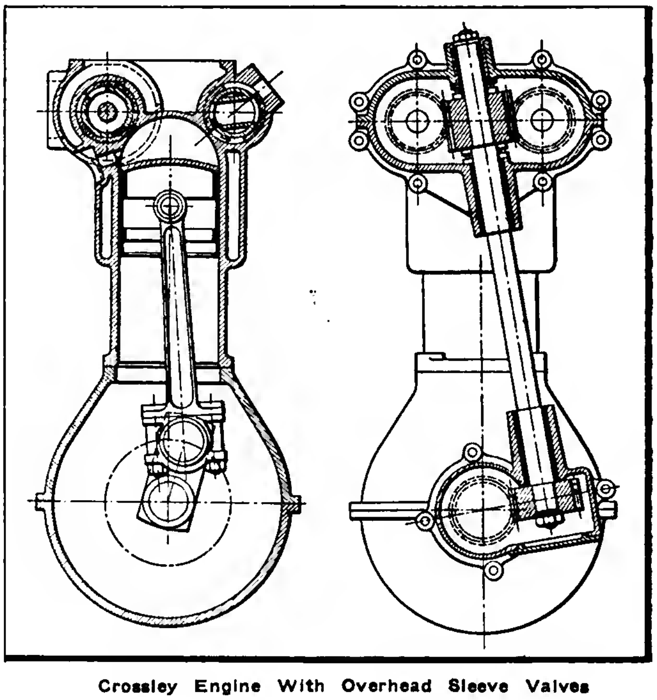
Another English sleeve valve engine, that of A. Reeves, Farnsborough, is very similar to the second one described, in that the ordinary cylinder (Tee-head) construction is unchanged, the valves being simply replaced by piston type of sleeves. He has this change, however, the inner or piston valve is operated in the usual way, with valve lifters, springs, etc., while the sleeve surrounding it is worked from an eccentric, by means of a rod.

It is hard to see that this has any advantage over the ordinary form, as the complications instead of being reduced are increased. More than this, by having the one valve, the inner, and thus the really important one, operated by a spring on the down stroke, it seems as if the biggest point in the sliding valves favor has been lost. The valves were made small in diameter, but of considerable movement, which gave to the valve chest, if it may be so called, a very long and narrow shape that was not displeasing to look at. The requisite amount of port opening was obtained by making the slots or ports very wide or high. The length would seem to call for rather high speed of valve movement, which in turn would seem to nullify the gain from height of valve port.

At any rate, whatever may be the merits and demerits of the various types of engines, and other parts described, their design, construction, testing and public appearance would all bear out the contention that whether intended or not, the Knight engine upset all the traditions of the automobile world, as to form of engine, some of which had been ten years in the making.



Variations in the Stroke from Lowest to Highest



Crossley Engine With Overhead Sleeve Valves

LETTERS INTERESTING

CLUTCH SPRING VALVES

Editor THE AUTOMOBILE:

[2,082]—I have a four-cylinder engine, four-cycle, bore 4¼ in., stroke, 5¾ in., and wish to attach a cone clutch to the same. The clutch is of 14 in. diameter, 2¼ in. face, and 10 deg., included angle, faced with leather. Is this surface ample to use with a spring of ¼-in. steel of 2-in. inside diameter, 6 in. long extended and 4¼ in. compressed? Kindly advise me as to the above.
Canaan, Conn. A. E. MOLANDO.

To answer this question correctly, it will be necessary to go into the clutch and spring problem rather deeply. It will also be necessary to know something about the power which the engine will develop. If we take the latter from the A. L. A. M. tables, and add a little to allow for the increased length of stroke, as well as to make an even figure to work with, we get 30 horsepower at 1040 r.p.m.

With this as a starter, the required spring pressure to transmit through the cone clutch described will be found using the formula:

$$P = \frac{H\ P \times 63{,}000 \times \sin\theta}{f \times r \times R}$$

in which, P equals the necessary spring pressure;
H P equals the horsepower;
R is the speed at which this power is transmitted;
sin θ is the sine of the clutch angle;
f is the coefficient of friction and
r is the mean radius of the clutch.

Supplying the required figures in this case, assuming the mean diameter as 13 in., which would make the mean radius 6.5 in., and assuming the coefficient of friction as .25, then we get the following:

$$P = \frac{30 \times 63{,}000 \times .174}{.25 \times 6.5 \times 1040} = 19.4 \text{ pounds.}$$

This spring pressure may be resolved into spring dimensions by using the well-known formula:

$$\delta = \frac{64 \times N \times L \times R^3}{E \times d^4}$$

in which δ equals the deflection of the spring in inches;
N is the number of free or complete coils;
L is the load in pounds;
R equals the mean radius of the wire used;
E is the modulus of elasticity, which may be taken as 11,500,000;
d is the diameter of the wire.

Now, in your case, we just found L to be 19.4 pounds, N must be determined, R is 2 ¼ in. and d is ¼ in. Then substituting:

$$1.75 = \frac{64 \times N \times L \times (2.25)^3}{11{,}500{,}000 \times (.25)^4}$$

from this we may evolve the following:

$N \times L = 111$;

now, L was just found to be 19.4, so that substituting it, we get

N equals 5.72 coils.

The conclusion then is that the spring will be all right for the clutch and engine described, if the spring has no less than 5¾ coils, or say 6 coils.

Clutch width is determined on a basis of average pressure, never exceeding a figure of 45 pounds per square inch. It is figured as follows:

$$W = \frac{z}{F \times 2\pi \times 45}$$

in which F is the same as r in the first formula, that is, the mean radius of the cone, while z is equal to resulting spring pressure or the axial pressure x divided by sin θ. This works out from previous figures to 1156 pounds. Then substituting, we get

$$W = \frac{1156}{6.5 \times 6.283 \times 45} = .65 \text{ in.}$$

It is at once apparent that the width which your clutch has is ample, being about 3 times as wide as is necessary, according to the formula. The answer to your question is that the clutch is very apparently all right, with the single proviso that the coiled spring must have 5¾ or 6 full coils.

KEEP GENERATOR WARM

Editor THE AUTOMOBILE:

[2,083]—Will you please tell me of some mixture to put in the tank of my gas generator, which will keep the water from freezing. I have no fear of radiator trouble, but am a bit worried in regard to the gas generator.
Corning, N. Y. J. H.

If you have reference to the water within the generator, anything added to this will reduce the amount of gas generated, and the ease and celerity with which the generator functions, that is, will have a tendency to clog it up.

On the other hand, if you refer to the water jacket around the outside of the generator, you can use anything you want to in that. In the past two or three weeks a number of anti-freezing mixtures have been given in the columns of THE AUTOMOBILE. Any one of these may be used.

On page 604 of the Oct. 7 issue, alcohol solutions were discussed in much detail, a curve of freezing temperatures of different mixtures being, both for denatured and wood alcohol. Then, in an earlier issue, that of Sept. 30, a similar curve was given for calcium chloride, showing how solutions of that vary as to freezing. On this page, you will find something about kerosene.

BRAND NEW ANTI-FREEZE

Editor THE AUTOMOBILE:

[2,084]—I would like you to inform me through "Letters Interesting, Answered and Discussed," as to why kerosene oil, commonly called coal oil, is not universally used in automobiles for anti-freezing purposes. I have heard of some individuals using it successfully and an all-kerosene solution is much cheaper than 25 or 30 per cent. alcohol solution. Maybe it is injurious, or what is the matter? Would offer as a suggestion to those using alcohol compound to plug up the overflow pipe when not in use to prevent the alcohol part from evaporating through the same, which would weaken the compound so it would have a lower freezing point than was originally intended. J. C. BROWN.
Riley, Wis.

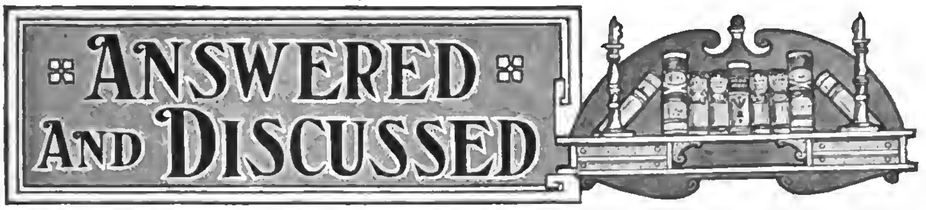
The last suggestion is a very good one, and should be brought to the attention of every automobilist using the alcohol solution. A cork could be carried around in the vest pocket for this purpose, and slipped into place every time the car was brought in from a run.

The first suggestion, on the other hand, is not a good one. Kerosene would be objectionable in that it would coat the walls of the radiator with a thin film of oil, and impair the conducting qualities of the metal composing those walls to such an extent as to reduce the capacity of the radiator for radiating heat to about one-third (1-3) that of the same radiator without an oil film. Worse than this, did you consider the effect of warming up about ten gallons of kerosene, and perhaps, holding a match over the vent pipe of the radiator?

If you did not, consider it now, for the result would be that you would make an unusually quick trip into the next county, if not into the next world. All kerosene needs to put it on a par with gasoline for explosive purposes is heat externally applied, just as the cylinders at about 250 degrees or possibly 300 degrees would supply. It seems as if the disadvantages of this scheme far outnumber and overbalance the gain.

Kerosene could not be used with water either, as oil and water will not mix. This makes it necessary either to accept your scheme as a whole or reject it as a whole. The latter is the best way, unless you "hanker" to visit the next county (or perhaps the next world) as indicated.

Why anyone would want to use a fuel for cooling purposes, is hard to explain, when it is an easy matter to get a real cooling mixture from substances, which never could, would, or should ignite, burn, or explode under any conditions whatever. The thing to do, is to get up a brand new cooling mixture from chemicals not now used, which will be superior to anything now in use.



KEEPS TO THE RIGHT

Editor THE AUTOMOBILE:

[2,085]—I drive a 1909 six-cylinder car, which has always had a tendency to steer to the right when running over an ordinary pavement or country road. The manufacturer has on different occasions replaced front axle, steering knuckle, and lined up the wheels, but the car still runs to the right. Do you think the trouble is in the steering mechanism, which is a screw and nut design? F. S. HARRISON.
Cleveland, O.

Whether the manufacturer changed any of the parts or not, it is a truism that if the car does not run straight normally, something must be out of true. The first thing to do is to find out what that is, so as to be able to correct it.

To go about this in a systematic and thorough manner, run the car onto a large, smooth, wooden floor, being particular to select a smooth one, as you will want to mark upon it. Then, with the car in an advantageous position, turn the front wheels straight ahead, or as near so as possible, and set the brakes.

Next secure a long steel square, such as carpenters use, being sure that both legs are more than 18 inches long. In addition, you will need a plumb line and bob. Using the latter, plumb down, or to put it otherwise, project, the front inside points of the frame as indicated on the sketch at A A. Having located these on the floor accurately, draw the line A-A to connect them. Bisect this at B, which will represent the center point of the front end of the car.

At the rear, project the corners C C, connect them with the line C-C, and find the center as at D. Draw the line B-D, which will represent the projection of the center line of the car. Now, with your square, project the front and rear points of each of the front wheels, in succession, as shown at E E, for the left front wheel, and F F for the right. Connect these by the lines E-E and F-F, to represent the center lines of the two wheels. In projecting the wheel points take particular care, in fact, to get these right you may have to project first one side of the wheel at the front end, then the other side, taking the center between the two as the actual center, and repeating for the other points.

Do the same for the rear wheels, obtaining the four points, G G and H H, from which draw the wheel center lines, G-G and H-H. Now, these may be bisected to obtain the centers at I and J, or the center of the hub cap or similar points may be projected to obtain it. In either way, obtain a projection of this center point on each side, and connect the two with the line I-K-J, K being the point where this line intersects the car center.

Going back to the front axle, project both sides of both ends, as at L L for the left end and M M for the right end. Take half of the difference between the two, being sure to do this accurately, and through the two resulting points, N and O, draw the front axle center line, prolonging it beyond the wheels as at Q-N-R-O-P. R will be the point of intersection with the car center line. Now, if you like, the car may be moved out of the way,

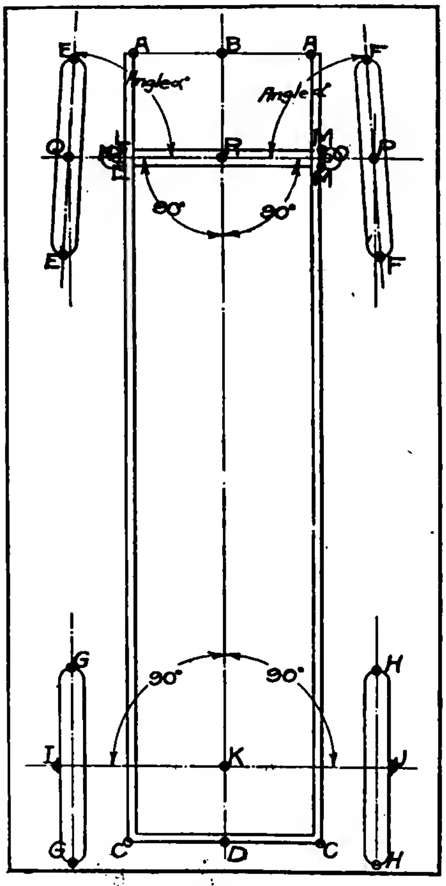


Diagram Showing Method of Lining Up Car

since all of the desired points have been obtained, and from these the car may be checked up, without the car itself.

Summing up the requirements for straight ahead running are four:

1. The angles NRK and ORK of the front axle center line with the car center line must each be exactly a right angle, that is, just 90 degrees.

2. The angles EQR and FPR of the front wheel center lines with the front axle center line must each be exactly the same, whether equal to 90 degrees or less, the latter being the more usual case.

3. The angles IKB and JKB of the rear axle center line with the car center line must be just exactly 90 degrees, a right angle.

4. The center lines of the rear wheels G-G and H-H must make exactly the same angle with the center line of the car, DKRB, whether that be 90 degrees or less, the former being more usual.

Having done this, you will know where you are at. It may surprise you to read the last two conditions, as the average owner has an idea that the alignment of the rear wheels has little or nothing to do with the straight ahead steering of the car, but such is not the case. The effect of disalignment of the rear wheels is very noticeable, in fact, it was one of the "bugaboos" which helped to make the chain-driven car less popular, the two chains having a tendency to pull differently, and thus pull one end of the axle.

In answer to your question, the type or construction of the steering gear would have little to do with a trouble of this sort, although it might be so connected up to the steering links as to pull to one side when apparently set to the middle of its throw. This could be corrected by simply turning the wheel a little farther to the one side.

MUST HAVE SOME NOISE

Editor THE AUTOMOBILE:

[2,086]—About two months ago I bought a Chalmers-Detroit "30" 1910 model, and am very well pleased with it in every way except that the differential produces a humming sound like an electric car. Some tell me to put in castor oil, and still others say graphite. I would appreciate it if you would tell me how to stop this humming, and also what causes it. G. D. STOLLENWERCK, JR.
Uniontown, Ala.

Some little noise in, or rather from, gears which mesh and run continuously is unavoidable. You can, however, reduce this very materially by using one of the lubricants spoken of. Between the two mentioned, the preference would lie with the latter, that is graphite. This should not be put in as clear graphite, but added to oil in about the proportion of a tablespoonful to a gallon of *good* oil. Note the italics. You should always use good oil, selecting it with the greatest of care, as much so in proportion as you would use in selecting a car. Running in oil of first quality, the gears will make as little noise as it is possible to have.

Another thing that you should remember is that gears, like cylinders and pistons, run in after a while, and then make much less noise than when new. From the record of the length of time you have had the car, it would seem as if you might begin to expect an improvement in this matter any time now, depending, of course, upon the amount of use which you give the car.

It is just barely possible that the shape of the differential case is such as to act as a sounding board for all noises which the gears make, thus really magnifying what little noise there is. Should you find this so, coat the inside with shellac.

Inter-State Model 30 Touring Car Fully Equipped with Top and Windshield

ALL the important features of the models made during the past season by the Interstate Automobile Company, Muncie, Ind., have been retained by the makers in the 1910 models, the details of which are now given out for the first time. The line consists of one chassis of 118-inch wheelbase, to which three standard types of bodies will be fitted. These will then be known as Models 30, 31 and 32, according as the body is a touring car, demi-tonneau or close coupled as some call it, or runabout, respectively.

Any or all of these—they are practically the same—sets a new value in the automobile world in that the worth of material, design, and workmanship for the money asked, is more than usual The wheelbase is long, the wheels are big and fitted with big tires, the springing is excellent, all of which go far toward making the riding qualities of the car as good as could be expected. Granting that all this may be had in a medium-price car—this one belongs in the $1,500 class—there seems to be little, if any, reason for paying more or looking farther.

Some changes have, of course, been made, such as the necessary refinements of detail, added to an increased wheelbase and larger cylinder bore, an improved type of clutch, a three-quarter elliptic rear spring suspension and more room in all styles of bodies. There is nothing omitted which could give better satisfaction in reliable running qualities, graceful appearance and economical up-keep. Improved features have been added in the later production, but only those which have been accepted universally as possessing exceptional merit.

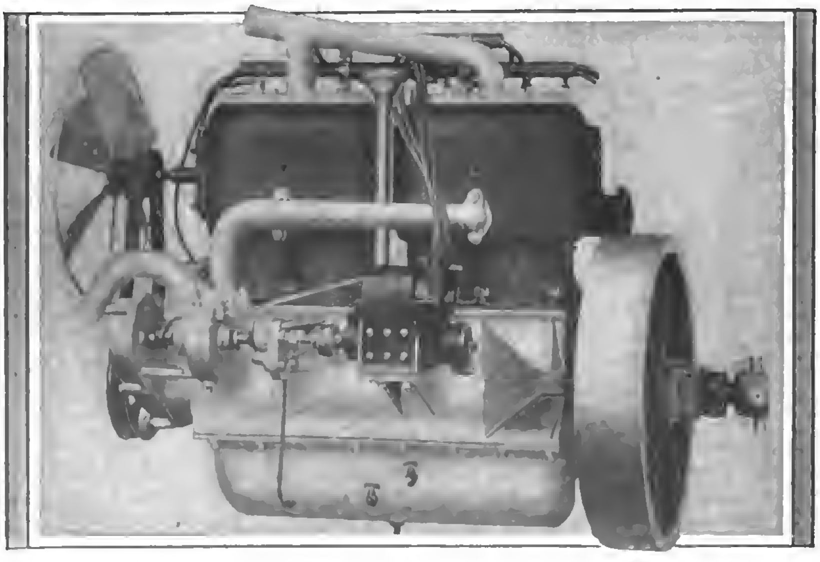
Among the motor changes are an increase of the cylinder bore, a larger cam shaft, the adoption of hardened and ground steel rolls in the push rods, giving frictionless rolling contact on the cams; a water-pump case integral with crankcase, and a rotary-gear oil pump on the outside of crankcase.

Four vertical cylinders with integral water-jackets and cast in pairs are given a high hydraulic test both before and after machining to discover any unseen sand spots or flaws. The bores are ground to exact dimensions, as well as the pistons and rings, and the latter are ground on the sides, assuring interchangeability. All are made of the finest gray iron.

All of the valves are located on one side with hardened and ground nickel-steel heads and ground stems, and both valves and passages are of large diameter, giving a high efficiency in power production. Valves are operated by a large single-piece camshaft, hardened and ground mechanically correct from generated master cams. The push rods contain hardened and ground steel rolls, giving rolling contact on cams, and eliminating all sliding contact on the cams. The whole construction assures a smooth, positive and noiseless action.

The crankshaft is made from a special carbon-steel forging, double-heat treated, and all bearing surfaces are ground to exact size. It is supported by three large main bearings, the center bearing support being integral with the crankcase. The rear and center bearings are adjustable for any possible wear. All bearings are of the very best bearing metal, which, in connection with the efficient lubricating system, assures long life under the unusually severe conditions met with.

High-Grade Materials, Aluminum and Vanadium—For the various parts of the car, the materials have been selected with much care, this, too, without any regard for the price. The light weight of aluminum is well known. So, too, is its high price per pound. Yet this medium-priced car uses it, and in large quantities, because the designers of the car considered it needed to round out the whole design in a proper manner.



Magneto and Pump Side of Inter-State 40 H.P. Motor

This is the material of the crankcase as well as the gearcase. The former is accurately machined by the use of many and various jigs, the expense of which is ungrudgingly borne in the desire for absolute accuracy and interchangeability. The oil reservoir is bolted directly to the bottom of crankcase. This is easily removed for adjustment or inspection of camshaft, crankshaft, connecting rods, or push pin rollers. It gives an accessibility which cannot be questioned, and still gives a very rigid crankcase. The lubrication is accomplished by the constant level splash system with a sight-feed indicator of latest type on the dash, indicating the flow of oil at all times from the reservoir to the crankcase. The constant level is maintained by a rotary-gear oil pump located on the side of the case and driven by the water-pump shaft. The oil reservoir holds two gallons, and receives the return from crankcase by gravity.

Motor cooling is effected by a fan-cooled radiator of the latest type and a fan flywheel, assuring perfect cooling at all times. A positive system of water circulation is maintained by a gear-driven centrifugal pump, the case of which is integral with the crankcase. Radiator cooling is by a ball-bearing fan, supported from motor and driven by a belt from the crankshaft.

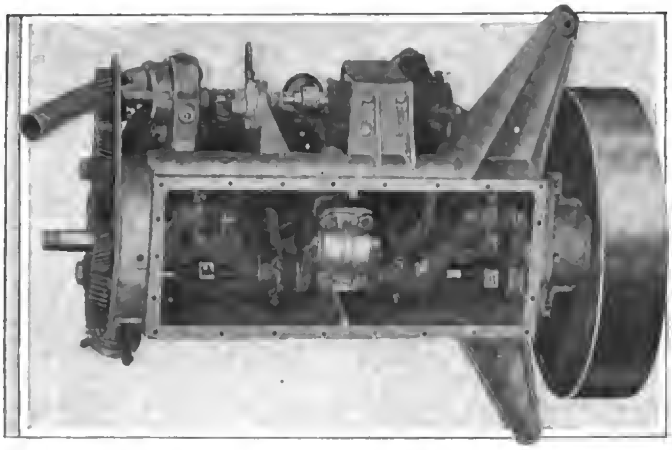
Ignition consists of two separate and distinct modes with a separate set of plugs for each system. The batteries, four-unit coil, timer and set of spark plugs constitute the first, and the second, a U. & H. imported high-tension magneto, with a separate set of spark plugs. Magneto is mounted on a standard of the crankcase and is directly connected to the pump shaft by an imported coupling.

The pump shaft is gear driven by a helical gear meshing with a helical camshaft gear and all gears are covered with an oil-tight case. The entire timing gears are of helical type, otherwise known as spiral gears, and they represent the highest type of high-speed gearing known, where smooth and noiseless action is required.

Helical Gears One of the Modern Refinements—This use of spiral gears, with their extra expense of cutting, indicates the modern trend toward the ultra-quiet car. This form of gearing is well known for its silence, and is used for that reason solely. The great cry nowadays is for quiet, absolutely quiet cars, and to answer, or rather, to forestall this, the spirally cut gears are used. The efficiency of well-cut gears of this variety being high, the losses to counterbalance the silence are practically negligible.

Gasoline is supplied by gravity pressure from a tank of large capacity and set high enough to assure a sufficient pressure on any grade likely to be encountered. The carbureter is of the latest float-feed type, having a visible gasoline level and easy and positive adjustment. It is automatic in its action and provides the proper mixture for all motor speeds. The throttle valve is controlled by a hand lever on the steering wheel and by a foot accelerator pedal conveniently located.

The drive is taken from the motor by a double universal joint of improved design, which can be disconnected without disturbing either motor or transmission, is practically noiseless, and easily lubricated, all important features.

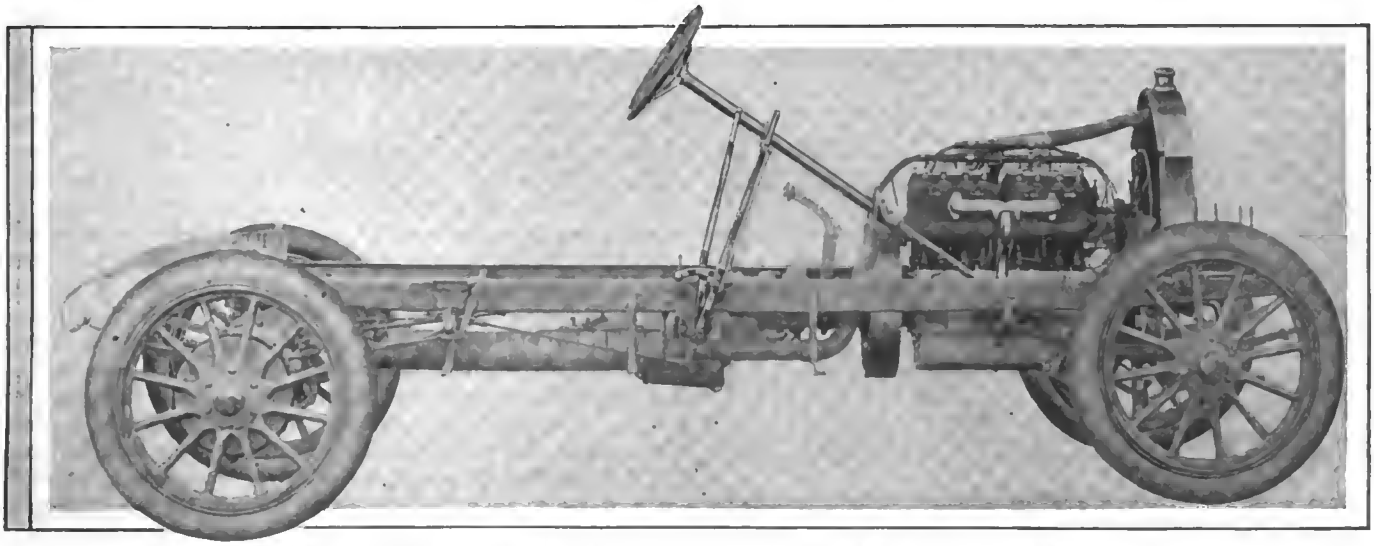


Crankcase Showing Bearings as Seen from Below

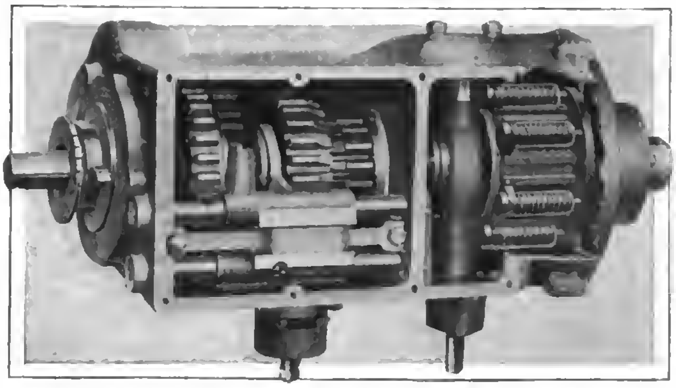
Features of Transmission and Clutch—An improved form of disc clutch is used, comprising 63 plates of tempered saw-blade steel running in a separate compartment integral with the transmission case. The large number of steel plates gives the same smooth positive action as from the use of bronze and yet has not the fast-wearing features of the bronze discs. A ball-thrust bearing between yoke collar and the clutch throwout yoke ring eliminates a large amount of friction and consequent wear. The clutch complete gives a smooth positive action at all times and the qualities described insure long life. The clutch tension is maintained by six spiral springs evenly spaced outside of the discs giving a very even thrust on the clutch discs and not depending upon the action of a single spring. This construction makes the failure of the clutch impossible from a single weakened or broken spring.

Inter-State design of transmission is well known for its durable construction and perfect ease of operation. The case is a high-grade aluminum casting, and the shafts are supported throughout on imported annular bearings.

Gear Details Sound Good—Nothing is more important than good materials, good workmanship, and efficient lubrication in the gearcase and gears, which give it the name. In this transmission all gears are of extra wide face and heavy pitch— five pitch being used throughout—and all gears in constant mesh are made of vanadium steel. The sliding gears shift on the four-keyed type of shaft and the keys are integral with shaft. All gearing is generated, hardened and ground, and chamfered with the most improved form of curve. A double locking device holds the gears and shifting lever in position and prevents



Side Elevation of Completed Chassis, Showing Inlet Side of Engine and Rake of Steering Column



Gearcase with Cover Removed Showing Clutch and Transmission

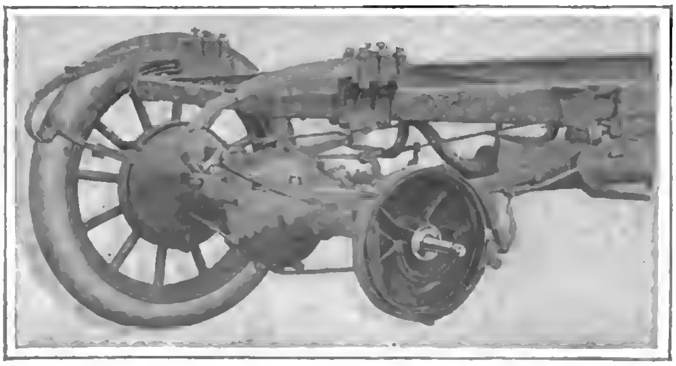
the careless driver from going by neutral position unintentionally.

Round or barrel-shaped is the name given to the gearcase, to describe the form of construction. This is in a single unit, with a large cover plate on the top for inspection purposes, being handy as well for adjustments and lubrications. The one-piece case is not only simple—a very good point—but it possesses added strength over any form of two-piece case, the division of the case representing a line of unavoidable weakness.

Propeller shaft is rigidly supported at both ends and the bevel drive pinion and gear and differential box are housed in an oiltight differential case. All bevel gears are carefully generated, assuring noiseless and efficient power transmission, and all the gears are easily removed. The axle shafts are of large dimensions, and made of very carefully selected steel.

Every motorist should look into the subject of brakes, for following the operation of starting the car, the next most important thing is to be able to stop. With the idea of stopping the car very quickly in emergencies, this one is fitted with four very large and efficient brakes. These are of the latest internal and external type, both working on the same drum attached to the rear wheels, one on the inside and the other on the outside. The two internal expanding brakes are used as service brakes. These are operated by foot pedal and are dustproof. All brake bands are lined with 2-inch thermoid lining and are provided with very simple adjustment. There is no transmission brake used, and, therefore, no stresses are imposed on the mechanism.

What the Springs Show in the Way of Merit—Springing has come to be regarded as one of the big problems of the automobile, and as such the details of the spring suspension of any car are worthy of more than ordinary scrutiny, particularly to the prospective purchaser. On this car an improved rear spring is of the three-quarter scroll-ended elliptic construction, affording more comfortable riding qualities. They are very rigidly suspended outside of the frame side rails and the wide spring base makes a more easy riding action of the car on rough roads. The rear springs are 45 inches long and the front springs are 42 inches long. All are 2 inches wide and made of vanadium steel, which means that they are unbreakable.



Rear Suspension Consists of Three-Quarter Elliptic Springs

Front axle is made of a high-carbon steel drop forging properly heat-treated and of I-beam construction. The steering knuckles are provided with extra large ball bearings fully ground and all connections are fitted with grease cups. The front axle road clearance is 11 inches and the rear axle clearance is 10 inches. The steel mud apron under the motor has an actual road clearance of 11 inches.

How the Frame Adds to the Whole—Since the units comprising the power plant, the clutch, transmission, springs, etc., all rest upon, or are attached to, the frame, that should have special treatment. It is of pressed steel, the channel section being employed to good advantage. The section of the stock used is unusually heavy, and is pressed out cold. The open side of the channel is turned in, so as to present a smooth exterior. At all corners and points where the cross-members are attached, heavy gusset plates are employed to retain the full strength.

Cross-members are four in number, located as follows: One at the extreme front, forming a bed for the radiator to rest upon; one passing under the front end of the engine, and forming the single point in the motor's three-point suspension; one just back of the flywheel and just forward of the transmission, lending stability at this hard-worked point, which comes at the dashboard; and the usual cross-member at the rear end.

At the dashboard, as just described, the bracing is worth special mention. Two unusually long triangular steel plates are riveted to the top and bottom of each side member, the lower one being much wider than the upper all along its length. Upon this widened lower member, the rear feet of the engine, extended in width for this particular purpose, rest thus forming the rear two points in the three-point support.

This unusual extra bracing, coming just at a point where the ordinary frame has its weakest point, is an excellent feature of an excellent car. The three-point suspension, too, is very good.

Engine bore, which has been omitted above, is 4 1-2 inches, while the stroke is 5 inches, the wheelbase is 118 inches, and the tread, standard, 56 1-2 inches. The wheels are 34 inches diameter all around, while the 4-inch diameter tires are also used on all four wheels.

Alumaloyd, the new aluminum-coated sheet steel, is the material for all bodies. This is bent to the desired shapes and used over bent-wood frames to hold that shape. The seats are of number one first quality buffed leather, stuffed with curled hair and fitted with spiral springs.

Unusually complete describes the equipment, which includes two gas headlights, with generator; two oil sidelights, one oil tail light, horn, tube, bulb, large combination tool and battery box placed on the left side of the car so as to leave the right or working side free, or if preferred for spare tires. The set of tools is complete and of the best makes throughout. The spare parts supplied are very complete, enough so to cover all small repairs for a whole season with ordinary careful driving.

MITCHELL EXPORTS GET DUTY DRAWBACK

WASHINGTON, D. C., Oct. 30—By ruling the United States Treasury Department, exports of automobiles by the Mitchell Motor Car Company, of Racine, Wis., will be allowed a drawback equal in amount to the duty paid on the imported materials used, less the legal deduction of 1 per cent. The materials include nickel alloy steel used in transmission and axle shafts and gears, ball bearings, aluminum crank and gear cases and parts of the Splitdorf magnetos.

The regulations set forth that the drawback entry must show the total number of automobiles exported, and the kinds and quantities of imported materials entering into the manufacture thereof, describing the several items as listed in the import invoices. The entry must further show, in addition to the usual declaration, that the exported automobiles were manufactured of the materials in accordance with the manufacturer's sworn statement filed with the collector of customs for the district.

Fig. 1—Model 0-3 touring car, with a roomy tonneau, wide side entrance, straight effect and metal body

WITH a brand new shop, ample and modern facilities, designers of skill, and a business establishment of wide experience, the Elkhart Motor Car Company, of Elkhart, Ind., is rapidly crystallizing, and the Model O series for 1910 will comprise some six separate styles of cars, one of which is shown in Fig. 1, and is a touring car, for five passengers, known as Model O-3, selling at $1,700.

A toy-tonneau, designated as Model O-2, using the same chassis, will undoubtedly be a popular type of car, and Model O-1, as shown in Fig. 2, is a roadster of caste. The toy tonneau will sell at the same price as the touring car, but the roadster will sell at $1,700, which is $50 below the touring prices, the difference being in the body.

Bodies All Equal in Point of Quality—The several types of bodies are with ash frames, properly joined, well ironed, and sheet metal is used for panels and doors. Upholstery is in M. B. leather of a careful selection, with spring cushions, and the standard colors of the finish are red, maroon, and black.

The touring car weighs 2,500 pounds, has a wheelbase of 118 inches, standard tread (56 inches), and the load is rolled on 12-spoked wheels, artillery type, using 34 x 3 1-2 inch Diamond tires, front and rear, with provision for 35 x 4 inch tires of the same make as an extra, at the option of the purchaser.

Power Plant Represents Competence—The motor, the right side of which is depicted in Fig. 3, is of the four-cylinder (vertical) type, placed in front, so that the radiator is over the front axle, and in this way the weight is so suspended between the front and hind axle that the performance of the car is superior. The cylinders of the motor are cast separate; of gray iron, with spherical domes, valves in heads, and rockers, R_1, R_2, R_3 and R_4, engaging tappet-rods, which are actuated by means of integral cams on a single camshaft, S, located within the crankcase, on the right side, driven by means of a silent (housed-in) gear, which meshes with a pinion on the crankshaft.

The carbureter, C, is also on the right side of the motor, and the manifold, M, is of the equalized type, made of aluminum, and properly proportioned, having in mind the fact that it is just as easy to exceed the requirement as it is to make the sectional area of the orifices too small. The location of the carbureter is advantageous, being high enough to be accessible, and low enough to afford a "hydraulic grade" for the gasoline in its migration from the nozzle to the cylinders, so that if some of it should fail to vaporize it will drain back to the carbureter, and the mixture will not be unbalanced by excesses of liquid being carried over.

Dual Ignition Includes Remy Magnetic—Besides a coil and battery, the latter comprised of dry cells, the Remy magneto is placed on the right side of the motor, on the pads, P, as shown (with the magneto removed), and is driven by a shaft which extends out of the gear housing, H, which meshes with the camshaft gear on the end of the camshaft, S. The ignition system, in view of the character of the devices used and the methods of installation, is up to a fitting standard, and the methods employed for advancing and retarding the spark renders the task of obtaining the maximum power from the motor but a matter of doing so.

The fan, F, Fig. 3, which is placed between the motor and the radiator, is of great capacity, having strong blades of liberal area, set at a well authenticated angle, and driven by a wide, flat belt, B, taking power from the crankshaft, through the good office of the pulley, P. The radiator, of the tubular type, is of adequate area of the cooling surfaces, and water is circulated by means of a gear-driven pump of good capacity.

The power of the motor, due to the use of 4 x 5-inch (bore and stroke, respectively) cylinders, is

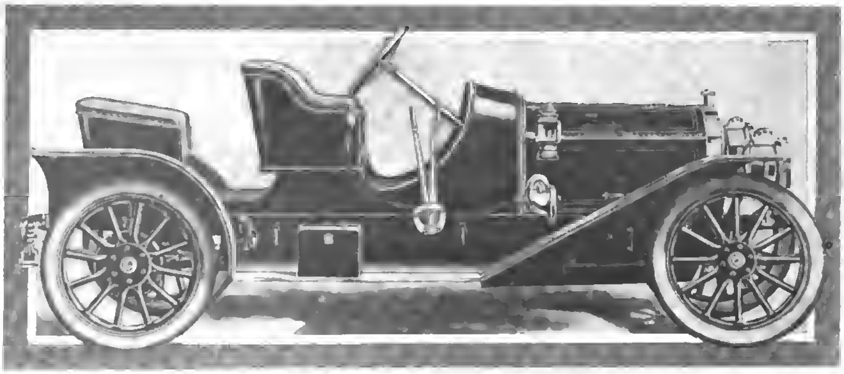


Fig. 2—Model 0-1 Roadster type, with runble seat in an accessible position, smart effect on the whole, and speed

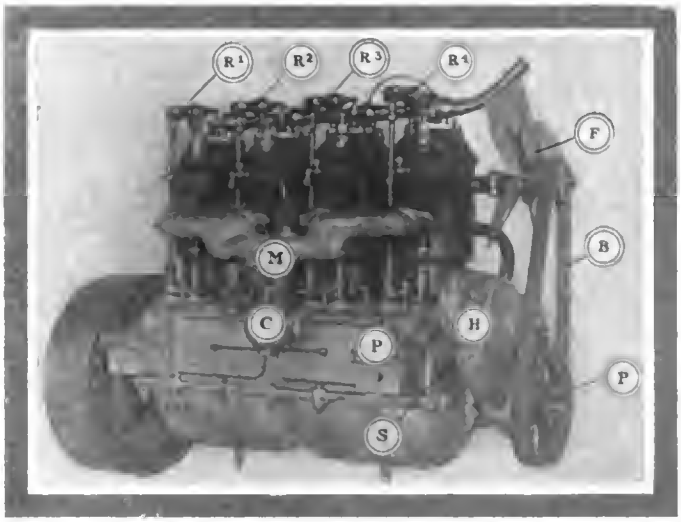

Fig. 3—Right side of Sterling 30-35 motor, of the individual cylinder, water-cooled type, overhead valves, belt-driven fan and furnished with magneto

large for the weight complete, and is rated by the makers at 30-35 horsepower. The crankshaft has five bearings, with a liberal projected area of each, and the motor delivers its power at about 800 revolutions per minute. Under these conditions, considering the use of Parson's white metal journals, it is a reasonable expectation that the motor will last long and work well. The even rotation of the crankshaft, under full load, and at low speeds, is accounted for, in a measure, by the well regulated compression, but the employment of suitable methods of design of the flywheel, considering adequacy of weight, has much to do with the good performance.

Clutch Represents Quality and Novelty—The clutch resides in the flywheel, comprises a cast extension 10 inches in diameter, machined and ground, and two accurately ground rings, side by side, extended by means of a toggle motion, press, at will, against the inner periphery of the ring. There is an entire absence of any facings, and the chances of wear are reduced to a minimum. The toggle motion affords very high surface pressures, and the clutch, while it is soft of engagement, is sure, with slipping eliminated excepting at the will of the driver, which, under certain conditions, is a positive advantage.

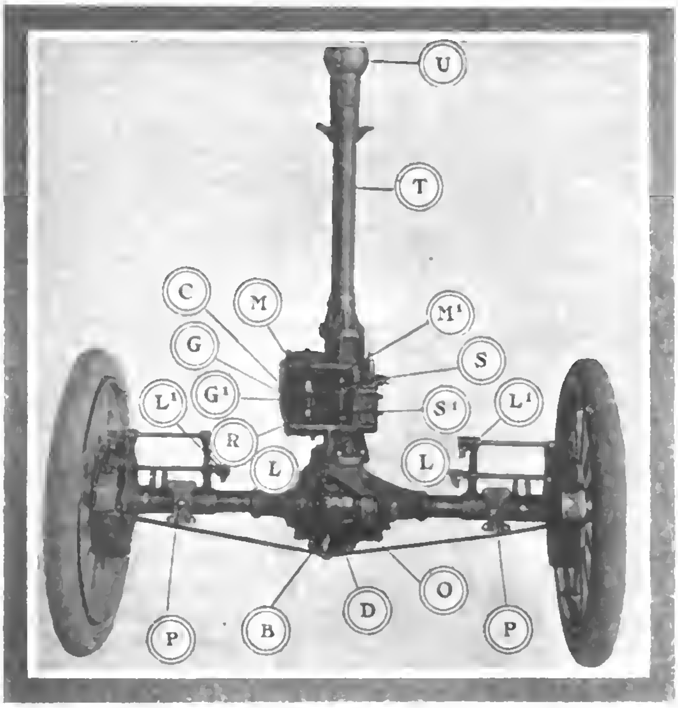

Fig. 4—Live rear axle, with transmission suspended, stout torsion tube, and protected brake levers

From the clutch to the rear axle, as shown in Fig. 4, is by means of a shaft, within a tube, T, on the end of which is a ball and socket universal joint, U, and between it and the bulge of the live rear axle the transmission case, C, is suspended. This transmission, deignated as the "Unit type," gives three forward speeds and reverse, and the direct, as well as the lay shafts, roll on New Departure ball bearings. The figure is from a photograph, with the cover of the transmission case removed, showing the master gears, M and M1, the change gears, G and G1, and the lay gear for the reverse, R, also the sliding sleeves, S, for direct on high and second, as well as S1 for third and reverse.

The bevel drive, by means of a bevel gear and pinion, is bolted to the differential housing, D, and the bevel gear, B, shows, the cover being off for the purpose. The differential gears are of the bevel type, and the case is provided with openings, O, at four points, to facilitate lubrication, one of which may be seen, and one of the differential gears may be spied through the opening. The tubing of the live rear axle is of the usual cold drawn, annealed, and brazed to make-up members of suitable contour.

Brake Control Members Are Inside—The control for the brakes extend in, past the perches, P P, for the springs, and the levers for applying pressure to the brake-shoes, L L and L1 and L1, are so placed as to be easily accessible, and what is equally to the point, out of harm's way. As indicated, there are two sets of brakes, both in drums in rear wheels, and the control is by foot pedal and side lever. The latter being for the emmergency brakes.

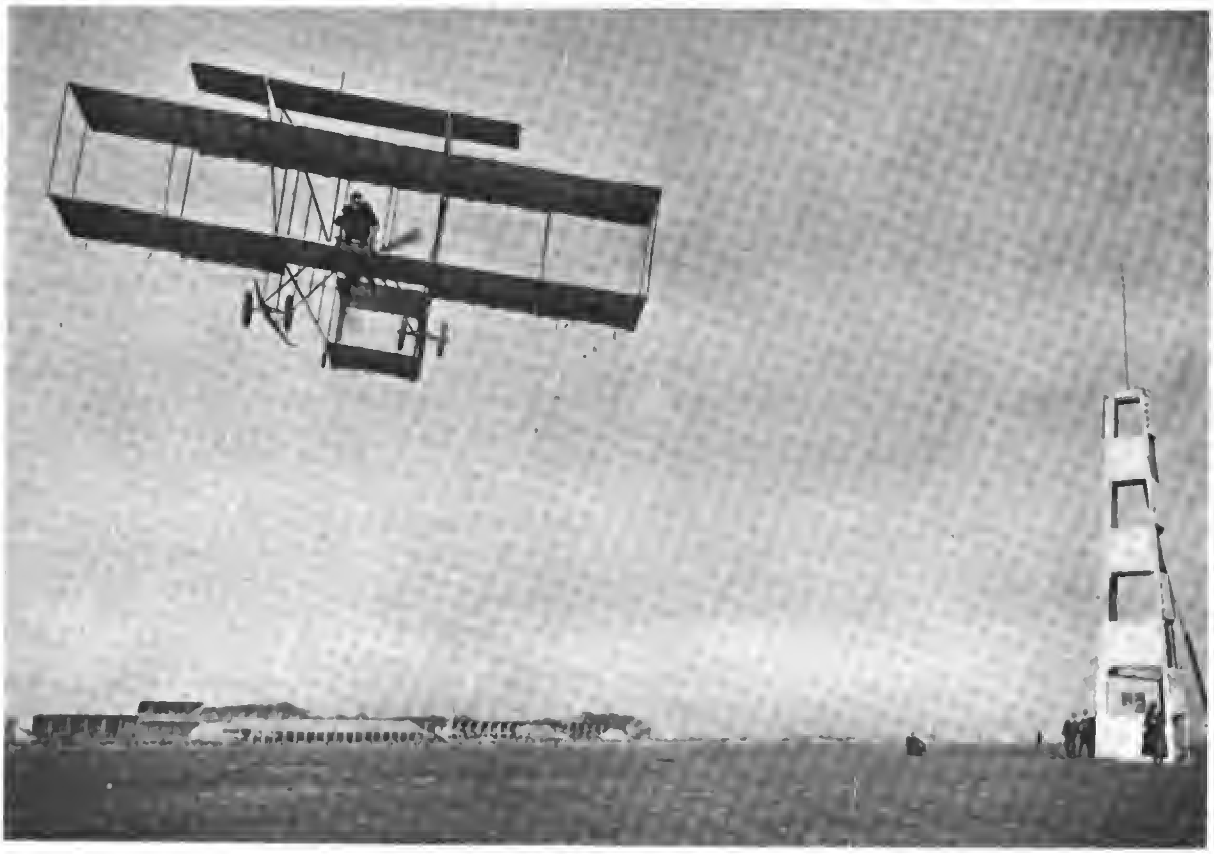
The front axle is of the I section, drop forged from special steel in one piece, and knuckles of good design, of the same grade of material, assure safety and long life free from lost motion. In the front wheels the ball bearings are designed for thrust and radial loading, with 5-8-inch balls inside and 1-2-inch balls outside. In the rear axle, which, by the way, is of the semi-floating type, is provided Hyatt roller bearings.

The chassis frame is a 4-inch channel section, pressed, with 3-inch cross members, and a grade of workmanship to assure the best results. The springs are of special grades of steel, 38 x 2 inch, semi-elleptic, front, and rear springs are of the platform type, 42 x 2-inch side members and 34 x 2-inch cross member, placed at the rear.

NEW ROYAL TOURIST MODELS OUT

In keeping with an old-established policy to avoid all revolutionary changes, and make only those which indicate mechanical progressiveness, the Royal Tourist Car Company, Cleveland, announces that the models for 1910 will be but a continuance of those for 1909 under a different name. The newer cars will be called Model M Series Two.

All of the cars of Series Two will retain the 5 1-2 by 6-in. motor of Series One, this having proved satisfactory in its predecessor. The motor has a speed range of from 5 to 65 miles an hour on high gear, actually developing 65 horsepower, and having an A. L. A. M. rating of 48.4. The manufacturers lay claim to having a machine that is a remarkable oil saver, an oil filter having been introduced and the oiling system having been further protected and simplified. The braking surface in this model is also a feature, being exceptionally large and correspondingly effective. One of the changes which greatly enhance the appearance of the car, is the adoption of a square dash made of Circassian walnut and also the employment of a longer hood, adding greatly to the lines of the car. Alloy steel is used exclusively in the frame, axles, steering knuckles and levers, as well as in all the gears and shafts in the transmission and in the rear axle. The car has a wheel base of 126 inches, 4 cylinders, and possesses all the very latest improvements known to automobile science.



Henry Farman, World's Record Holder for Distance and Duration, Making a Recent Flight at Blackpool, England

NEW YORK CITY PLANNING AERO MEET

Long Island is to have an aeroplane meet rivaling those of Rheims and Blackpool, if the plans of the Aero Club of America materialize. This announcement was brought forth by the return of Orville Wright on the *Adriatic* last Thursday, and the news of Farman's new endurance record on Wednesday. The particular connection between these two events is that Farman's flight was in competition for the Michelin trophy, an annual prize for the longest flight during each calendar year. This prize was won in 1908 by Wilbur Wright, with a flight of 76.5 miles in 2 hours 18 minutes 38 seconds.

The brothers naturally wish to keep it in the family, and although neither has definitely said that he would attempt to beat Farman's record, it is reasonably sure that they will appear at the coming meet. Wilbur Wright is authority for the statement that whoever wins the Michelin prize this year will have to fly from daylight till dark—at least eight hours of a midwinter day. According to the Aero Club's semi-official statement, the meet will take place at Belmont Park race track, near the Vanderbilt Cup course, during the last week of the year.

Orville Wright and Miss Katherine Wright were met at the pier by Wilbur Wright and President C. F. Bishop and W. J. Hammer of the Aero Club of America. The junior member of the partnership has been in Europe since August 10, and has made during this time approximately 100 flights. While in Germany Mr. Wright instructed Captain Engelhart, a retired naval officer, in the use of the aeroplane. He will in turn act as instructor for the German firm that is making Wright machines.

CROSS OF LEGION OF HONOR FOR WRIGHTS

Orville and Wilbur Wright have received the French Cross of the Legion of Honor, the greatest reward which the French Republic can confer, as a recognition of their labors in the field of aviation. The ceremony took place last Saturday at the French Consulate in New York, and Consul-General Georges Lanel, acting in behalf of the President of France, made the presentation.

GOVERNMENT AEROPLANE DAMAGED

WASHINGTON, D. C., Nov. 5—After on one memorable flight showing its possibilities in the hands of the military aviation corps, the Government's Wright aeroplane was badly damaged this morning, and will be laid up for at least a week. Lieutenant Lahm was driving this morning, with Lieutenant Humphreys as passenger. The accident apparently resulted from the faulty performance of the motor, which missed fire badly, causing the aeroplane to sink nearer the ground. The operators apparently failed to notice this, for they attempted a turn, and as the machine heeled over the right wing-tip struck the earth. It looked like a bad smashup, but the only injury sustained by either officer was a scratch on Lieutenant Lahm's nose. The machine will have to have its right lower wing-tip and the right skid replaced.

Wednesday morning the aeroplane made its best record, Lieutenants Foulois and Humphreys remaining aloft for 1 hour 1 minute 45 seconds, falling only ten minutes short of the world's record for flight with passenger. They came down at Wilbur Wright's request, because of the rising wind.

FARMAN'S MICHELIN FLIGHT A RECORD

PARIS, Nov. 3—Henry Farman broke all world's records for distance and duration to-day in a flight for the Michelin trophy at Chalons. He covered 144 miles in the time of 4 hours 17 minutes 53 seconds. It was a cold, gray day, but windless; the aviator's greatest difficulty was to keep his hands and arms from becoming numbed. The best previous records were made by Farman at the Rheims meet last August, when he made 111.8 miles in 3 hours 4 minutes 56 2-5 seconds.

The new record, being made under the officially prescribed conditions, will win the Michelin trophy for Farman unless surpassed by some other aviator before the end of the year. The Michelin trophy was instituted by M. Michelin in 1908. It consists of the sum of $32,000, divided into eight annual prizes of $4,000 each. The winner each year receives in addition a bronze trophy, and the club which he represents a similar trophy.

ADAPTING CARS TO ROADS

Wiseacres—not all of them of rural origin—used to say, with much shaking of heads, that automobiles would never find much use in the country districts until they were adapted to country roads. Automobiles were fine things, said these prophets, to run on the macadam roads between large cities, and no doubt they were useful and had come to stay, etc., but they were not practical for the farmer's use. The first qualification mentioned was always high wheels.

It is hard to tell who has won. The prophets, of course, say that modern tendencies in automobile construction are the result of considering the demands of the country trade. The automobile manufacturers, on the other hand, say that the tendencies are the result of a natural evolution. It is certain that these developments add immeasurably to the comfort of the occupants, even on the best macadam roads.

At any rate, the automobile makers have taken up large wheels with a will—note, we now call them "large," and not "high." The makers of the buggy or "high-wheel" type of automobile now find that the makers of the more legitimate type have stolen their loudest thunder. In at least two cases the size of wheels of the regulars equals that of the former insurgent type; and in addition to these large wheels, the regulars have a length of wheelbase that gives them a further advantage.

These developments in the regular line are not at all confined to the high-priced cars. The medium and low-price classes are also in the movement for longer wheelbase and larger wheels. No one would dare try to sell a five-passenger car with 28-inch wheels and 80-inch wheelbase, such as we knew to our sorrow in the old days, on the plea that it was "cheap." For a $1,500 car the average is now 110 inches base and 34-inch wheels, with 36-inch not more than a year ahead.

Larger wheels have helped out materially on the question of clearance. This very important dimension is now never less than ten inches, and ranges up to twelve in a number of cases.

"Natural evolution" is a fine, mouth-filling phrase, and may mean something; on the other hand, we suspect that not a few makers of the regular type have cast longing eyes on the fat farm-lands west of the Mississippi and south of the Ohio. Without awarding victory to either side, it suffices that large wheels, ample clearance and long wheelbase are now standard features.

NOISE AND ITS ELIMINATION

Each day of each week, in an unending stream, this office receives letters on the subject of noise. They begin, "How shall I stop the noise of my differential?" "How may I take the hum out of my gears?" "How can I stop the noise of this, and of that, and of the other thing?" Some of these questions are not wisely asked, but throughout all of them there is a great and very apparent tendency toward the absolute elimination of all automobile noises.

Far from lessening with more and more quiet machines, this is a matter which seems to grow constantly worse. In this way, the standard set a few years ago is quickly replaced by a new and higher one, up to which manufacturers bring their cars, only to be met with fresh demands for the abolition of this or that thing, which makes a "little" noise.

First among the remedies applied to this matter was the correct and regular chamfering of clash gear teeth as opposed to the old inaccurate hand trimming methods. This made gear changing more quiet, but then the engine was too noisy. The latter outcry brought out the enclosure of the whole valve mechanism, and the deadening of the lifter and valve stem impact by means of fibre, rawhide and other sound-reducing materials.

Following that, improved valve setting, combined with more efficient muffling reduced the noise of the exhaust to a minimum. Then, some slight improvements in carbureters and carburetion reduced the noises of the fuel inflow to as negligible a quantity as was possible. The enclosure of brakes and some of the brake mechanism helped a little, as did also the universal adoption of the mud pan, with a noise-deadening air space between it and the base of the motor.

But even all these and the reduction in noises which they produced was not enough, and the cry of less noise is probably more heard to-day than ever before. It may be among the possibilities that the success of the slide valve engine when firmly established will help very materially in this direction, for this design of motor does away with the noisy and troublesome valve mechanism, toward the quieting of which much time, thought and work have been devoted.

COL. CLIFTON RE-ELECTED PRESIDENT OF A. L. A. M.

AT the annual meeting of the Association of Licensed Automobile Manufacturers held at the general offices of the Association, 7 East Forty-second street, New York City, November 4, the following officers were elected for the ensuing year: President, Charles Clifton, Pierce-Arrow Motor Car Company; vice-president, S. T. Davis, Jr., Locomobile Company of America; secretary, L. H. Kettredge, Peerless Motor Car Company; treasurer, Col. George Pope, Pope Manufacturing Company. The executive committee of the association is made up of the following: President Clifton, Vice-president Davis, Hugh Chalmers, Chalmers-Detroit Motor Company; Thomas Henderson, Winton Motor Carriage Company; Herbert Lloyd, Columbia Motor Car Company.

In addition to the above-mentioned officers, the following members of the Association were in attendance at the meeting: James Joyce, American Locomotive Company; Elmer Apperson, Apperson Bros. Automobile Company; John S. Clarke and D. S. Ludlum, Autocar Company; W. C. Durant and R. H. Goss, Buick Motor Company; W. C. Leland, Cadillac Motor Car Company; R. D. Chapin, Chalmers-Detroit Motor Company; H. W. Nuckols, Columbia Motor Car Company; M. S. Hart, Corbin Motor Vehicle Corporation; R. M. Brownson, Everitt-Metzger-Flanders Company; James H. Becker, Elmore Manufacturing Company; G. H. Stilwell, H. H. Franklin Manufacturing Company; Elwood Haynes, Haynes Automobile Company; Edward R. Hewitt, Hewitt Motor Company; R. B. Jackson, Hudson Motor Car Company; Alfred N. Mayo, Knox Automobile Company; H. A. Lozier, Lozier Motor Company; F. F. Matheson, Matheson Motor Car Company; Benjamin Briscoe, Maxwell-Briscoe Motor Company; C. R. Hathaway, Olds Motor Works; Henry B. Joy, Packard Motor Car Company; Albert L. Pope, Pope Manufacturing Company; R. E. Olds, Reo Motor Car Company; George J. Dunham, Royal Tourist Car Company; W. Mitchell, Alden Sampson, 2d; R. H. Salmons, Selden Motor Vehicle Company; Frank B. Stearns, F. B. Stearns Company; William R. Innis, Studebaker Automobile Company; E. R. Thomas and E. L. Thomas, E. R. Thomas Motor Company; John N. Willys, Toledo Motor Company; William T. White, Walter Automobile Company, and Windsor T. White, Waltham Manufacturing Company.

LACK OF SPACE AT PALACE SHOW A SERIOUS PROBLEM

JUST how to meet the demands for space of the 300 odd exhibitors in the coming Grand Central Palace Show, which opens on New Year's Eve, is getting to be a more serious problem every year. Not only do the manufacturers want more space each year to exhibit their cars in, but the ever-increasing demands of the accessory people make the erection of a more commodious exhibition building almost a necessity.

Manager W. M. Sweet, of the Motor and Accessory Manufacturers, in discussing this question, said: "Last year our association took 14,500 square feet of space in the Palace show, which was divided between 89 exhibitors. This year we have 103 members who will exhibit at the Palace show, and could use at least 20,000 square feet of space, yet all we can secure is 14,870 square feet, or about the same as last year.

"Our association is composed of the manufacturers of motors, motor parts, appliances or accessories used on or in connection with motor vehicles of every description. This includes tires, lamps, axles, motors, transmissions, gears, roller or ball bearings, shock absorbers, speedometers, springs, tops, carburetors, oilers, timers, batteries, radiators, hoods, etc. In fact, from the ranks of our members one could obtain all the material necessary for the construction of any type of machine on the market, provided we would sell them parts, which could not be done, as we cannot make quarter enough parts now to supply the legitimate needs of the automobile manufacturers."

As usual, all the exhibitors at the Palace show will be supplied with a distinctive sign for their booth in harmony with the general scheme of decoration adopted for this year's show. Unitt & Wickes, who have the decorations in charge, have designed a special sign which, in some form or other, will be used throughout the entire building. Standards of trellis work will support alabaster glass signs in which the firm's name will be printed in Egyptian letters of gold on a green ground, which will be illuminated from the rear by colored electric lights.

NOVEL RATHSKELLER FOR GARDEN SHOW

What promises to be a revelation in the rathskeller line is promised for the Tenth National Automobile Show at Madison Square Garden, January 8-15. Every nook and cranny of the historic building has been considered in the scheme of decoration, and those who have been privileged to see the decorative scheme adopted for the forthcoming show say that the big amphitheater will present a scene of unsurpassed grandeur that will make it unrecognizable to its regular patrons. The basement, where the commercial vehicles and motorcycles are to be on view, will be decorated more attractively than ever before and here, buried among dangling foliage, the rathskeller will be found. The rathskeller is of the Dutch Colonial type and is painted in cream white. The entrance with its two Doric columns is unique, and it is said that there is nothing along New York's "great white way" to compare with it. Crimson and green ramblers, clinging to lattice work effects adorn the edges of the inn and autumnal foliage trails to the top of it, on both sides of the entrance. There is a passageway on either side of the inn and a glimpse of what is within its walls can be had by peeping through the old-fashioned windows. Bay trees in boxes adorn the base of each column in front of the inn.

MILWAUKEE CLUB DECIDES SHOW DATE

MILWAUKEE, WIS., Nov. 8—The Milwaukee Automobile Club has practically decided on February 22 to 27 as the date for the second annual Milwaukee automobile show, and an option has been taken for that time on the new $500,000 Auditorium. The show committee consists of Lee A. Dearholt, Dr. Louis Fuldner, Christian Schlotka, Oscar A. Fischedick and A. C. Brenkle. The Auditorium is regarded as an ideal place for an automobile show, having an immense oval arena surrounded by seats. The building covers an entire block, including many smaller halls which can be used for accessory exhibits. Additional space here will allow twice the size of show that was possible last year.

MID-OHIO PLANS FOR AUTOMOBILE SHOW

COLUMBUS, O., Nov. 8—Arrangements for the automobile show to be held under the auspices of the Columbus Automobile Club December 25 to January 1, are progressing satisfactorily. More than half of the available space has already been contracted for, and the rest is going fast. In addition to the manufacturers represented in Columbus, a number of others have applied for space, and accessories will also be exhibited.

STATE AID FAVORED BY NATIONAL ROAD CONGRESS

COLUMBUS, O., Nov. 8—That the principle of State aid for the improvement of highways should be adopted in every locality in the United States was the consensus of opinion expressed by the 2,500 delegates that attended the National Congress of Road Builders and the annual meeting of the American Road Makers' Association, which closed their sessions October 29, after four days of instructive deliberation in this city. While no formal resolution to that effect was adopted, the leaders in the good roads movement from every State of the Union favored the plan. Men who have taken a prominent part in highway supervision and construction in many States spoke of their experiences and gained ideas from others.

The meeting was the largest good roads congress ever held in the Middle West, and probably in the United States. Delegates from practically every State which has a highway commission and many from other States and territories were in attendance, and exchanged views.

One of the features of the meeting was the address of Samuel H. Hill, an adopted son and son-in-law of James J. Hill, the Western railroad magnate. He hailed from Seattle, Wash., and delivered a long talk on "Blazing the Way on the Pacific Coast." Mr. Hill advocated the employment of convicts in road building, and believes that the highways can be improved with less cost in that manner. He told of the experience of himself and associates six years ago securing convicts to build Washington roads.

Addresses were made by James H. MacDonald, State highway commissioner of Connecticut; John Bristow, State highway commissioner of Rhode Island; Horatio S. Earle, State highway commissioner of Michigan; Charles P. Light, State highway commissioner of West Virginia; S. P. Hooker, chairman of the commission of State Highways of New York; R. D. Beeman, assistant highway commissioner of Pennsylvania; Paul D. Sargent, State highway commissioner of Maine; J. C. Wonders. State highway commissioner of Ohio; Fred H. Caley, State registrar of automobiles for Ohio, and a number of others of note.

One of the matters of interest considered by the meeting was the question of freight rates on road making materials. A resolution was adopted directing the president to take up the matter with the railroads, and see if a lower rate could not be obtained, the present tariffs being much too high.

Hundreds of delegates inspected the large exhibits of road-building machinery and materials at the State Fair Grounds, where part of the sessions of the congress were held. The demonstration of a water-bound macadam highway in process of construction under the charge of the county engineer also attracted widespread attention.

One of the most important projects which will receive the support of the Ohio Good Roads Federation is the Alsdorf county aid bill, with the new provision for perpetual maintenance. The State association urged the appointment by the governor of a perpetual commission to have charge of the State's highways. This latter plan was opposed, however, by the larger convention, the Road Makers' Association.

The annual election of officers of the American Road Makers' Association resulted in the re-election of James H. MacDonald, of Hartford, Conn., president; Samuel H. Hill, Seattle, Wash., vice-president; E. L. Powers, New York, secretary, and Joseph W. Hunter, Harrisburg, Pa., treasurer. A number of cities are desirous of having the 1910 convention, the place and date for which will be fixed by the executive committee.

Delegates to the international road congress to be held in H. MacDonald, E. L. Powers, S. H. Hill and A. C. Campbell.

SOUTHERN AUTOISTS FORM STATE BODIES

Three new clubs were elected to membership in the American Automobile Association at the regular monthly meeting of the executive committee, held recently at national headquarters, 437 Fifth avenue, New York. They were: Atlanta Automobile Association, of Atlanta, Ga.; Waco Automobile Club, Waco, Texas, and the Rowan County Automobile Club, Salisbury, N. C. At the same time favorable reports were received indicating that active work is progressing toward the formation of State associations in Texas, North Carolina, Alabama and Florida. Secretary B. M. Reed, of the Tampa Club, stated that automobile interest was increasing rapidly in all parts of Florida, and the clubs that are likely to be affiliated with the State body will be the Tampa, Daytona, De Land, Orlando, Bartow, Brookville, Ocala, Gainesville and Jacksonville local organizations.

President Lewis R. Speare, of Boston, who presided at the meeting, announced the appointment of Ralph W. Smith, president of the Denver Motor Club, also president of the Colorado State A. A., as a member of the A. A. A. executive committee.

Secretary Frederick H. Elliott was instructed to make arrangements for the customary reduced railroad rates for A.A.A. members desiring to attend some of the meetings to be held in New York City during the coming two big automobile shows, the Grand Central Palace show from Dec. 31 to Jan. 7, and the Madison Square Garden show from Jan. 8 to 15.

THANKSGIVING CLIMB ALONG THE HUDSON

OSSINING, N. Y., Nov. 8—The Upper Westchester Automobile Club will hold a hill-climb on Thanksgiving Day, November 25, on a one-mile course over Sunset Hill, near this city. There will be seven classes, open to all, arranged by price classificatiions and with divisions for stripped chassis and steam cars, as well as a free-for-all. Entries close November 23, with a $4 fee.

VANDERBILT WINNER IS DINED AT THE HUB

BOSTON, Nov. 6—In recognition of the fact that two of the three winners in the Vanderbilt Cup race were Boston men, the Bay State Automobile Association this evening gave a banquet in honor of Harry Grant and Joseph Matson, drivers, respectively, of the Alco that captured the Vanderbilt Cup and of the Chalmers-Detroit that won the Massapequa trophy. Mr. Grant was present, but Mr. Matson was obliged to leave for Atlanta for the races on the new speedway and so could not attend. He was represented, however, by A. E. Gilmore, Boston representative of the Chalmers car. Frederic Tudor, president of the Bay State Association, presided, and with him at the head table, besides Mr. Grant, was L. R. Speare, president of the American Automobile Association. About fifty members of the club were present. Gold fobs bearing the emblem of the Bay State Association, were presented to Grant and to Mr. Gilmore, representing Matson. The speakers included the guest of honor, President Tudor, Mr. Speare, James Fortescue, Frank E. Wing, representative of the Marmon that won the Wheatley Hills trophy; Charles J. Glidden, J. W. Bowman and A. E. Morrison.

DINNER DAY CLIMB OPPOSITE NEW YORK

New York dealers have promised their support to the proposed Edgewater-Fort Lee hill climb, on the Jersey side of the Hudson, and this event is now assured for Thanksgiving Day. The climb will be conducted by the Edgewater Motoring Society. The provision in the New Jersey laws forbidding racing will, it is said, be dodged by sending the cars up one at a time, so that, legally, they will not be racing. The trials will begin at 10 a. m. and will end by noon. W. J. Morgan is the New York representative, at his office in the Thoroughfare Building. A big delegation from New York is expected to attend.

AMONG THE BUSY FACTORIES IN THE BADGER STATE

RACINE, WIS., Nov. 7—Without going to Wisconsin and visiting such centers as Racine, it will be impossible to realize the extent of the automobile invasion. Wisconsin is an ideal center for this industry, and besides an abundance of skilled labor there is material to be had, and many natural advantages besides business acumen.

The Mitchell Motor Car Company, not going back more than three years, shows progress that may be set down as follows: Cars constructed during 1908, 1,800; and in 1909, 3,200. For 1910 the output is estimated to be 6,000, for which material is now in hand on a basis of 85 per cent. The value of the Mitchell product for these years was estimated by the company as follows: 1908, $2,000,000; 1909, $3,500,000, and for 1910 it is expected that the output of the company will foot up to the comfortable sum of $7,500,000. The number of men employed during the last three years may be approximated as follows: 1908, 500; 1909, 1,000, and this force has increased to 2,500. with the chance that it will be augmented considerably in the near course of events. All cars up to the limit of the output, in view of the machine tools actually in hand, have been sold and there are demands which may be satisfied, in excess of the expected output of about 1,200 cars. At the plant, everything is made excepting tires, magnetos and some unimportant small parts. The plant spreads over considerable space, increasing from 3 acres in 1908 to 6½ acres in 1909, and 13 acres at this time, counting floor space; the grounds spread over some 40 acres and expansion is therefore but a matter of continuing the Mitchell brand of activity.

Pierce Motor Car Company, having added 36,400 square feet of floor space, thus bringing the plant up to 96,400 square feet, has 500 of the new Model K, known as the Pierce 30, under way, and while the plant is just as busy as the management can make it, the question of the exact number of cars, over and above the number as here indicated, is a matter which can not be stated with certainty. At all events the Pierce is a "built" car, and this means much, since the amount of work to be done in the shop of the maker is enormously increased over a parts undertaking.

Racine Manufacturing Company, with 12,000 bodies to its credit for last year, is now turning out 100 bodies per day, and at is claimed by the management that this rate will be increased to 125 bodies per day within three months. It is stated that the trend is in the direction of metal bodies, using steel, and ash framing is being continued as the most reliable wood to employ, having in mind the necessity of properly joining and "ironing" the framing. Aluminum and wooden bodies are made by this company as well, and it is noteworthy that the taxicab business is having a vast influence on the amount of work in hand and in prospect.

KENOSHA, WIS., Nov. 8—Thomas B. Jeffery & Company, authoritatively announce that all the 1910 Rambler models will be designated as "The New Ramblers." This name has been chosen, it is said, to call attention to the success of the Rambler makers in their effort to make the new models more distinct even than their predecessors in point of quality, dignity, silence, and comfort.

The Badger Brass Company, maker of lamps, generators, and lighting equipment in general for use in automobile work, invited THE AUTOMOBILE representative to stay a few days and get a line on the class of work which is being done. It will be impossible to fairly depict the situation without doing so, and this detailed inspection is to take place early in November. In the mean time it is fair to say that the company is pushing work as fast as quality will admit of, and the line for 1910, which is well disposed of, will offer evidences of novelty in the contemplated description.

HUSTLING ILLINOIS TOWN HAS AUTO BOOM

SYCAMORE, ILL., Nov. 6—In the midst of a rich farming land, the town of Sycamore occupies a strong position, and while trade is the more important occupation of the residents, even so, manufacture is making inroads, and among the more prosperous of the industries of the town will be found the Turner Brass Works, makers of a hundred varieties of gasoline torches, some of which are especially for automobile work. With a foundry of competence, the company is turning out a line of brass and aluminum of every description, and the great variety of name plates made, for illustration, is worthy of note. Then, the "Harroun" auto bumper is a company product, and for this well-known device the demand is so great that the makers are having difficulty in keeping up with orders.

Sycamore will soon bask in the sunlight of a great new automobile project. The Fidelity Motor Car Works, with a plant of some pretence available, and plans in a large way under discussion, will place before discriminating buyers of commercials, a line of commercial vehicles, which, for up-to-date features, will represent the top of the designer's ingenuity.

EAMES TOURING STUDEBAKER BRANCHES

CLEVELAND, Nov. 8—Hayden Eames and Le Roy Pelletier, general manager and advertising manager, respectively, of the Studebaker Automobile Company, have during the past month been making an extended tour of the various Studebaker branches, covering over 15,000 miles. The itinerary included Salt Lake City, San Francisco, Portland, Seattle, Minneapolis and Chicago.

Mr. Eames says that to an even greater extent than last year the automobile manufacturers' problem is to meet the demand, which is particularly strong for the medium-priced cars. Even if the 200,000 cars which are predicted for next season could be built, the supply would still be inadequate. However, Mr. Eames, from his knowledge of the material and parts markets, believes that this prediction is far too high, and that the correct figure will be found about 125,000—certainly not over 150,000 cars. The Studebaker-E. M. F. factory in Detroit is now turning out about 1,200 cars a month.

During the present week Messrs. Eames and Pelletier will continue their tour, visiting New York, Boston and Philadelphia, and concluding at the Atlanta show.

TRADE CHANGES IN OHIO'S CAPITAL

COLUMBUS, O., Nov. 8—The F. H. Lawell Company, which has been handling the Franklin, will be succeeded by the Franklin Motor Car Company, to be located at Spring and Fourth streets. The new company will also handle the Reo. F. H. Lawell remains general manager. The Speedwell Company, of Dayton, O., will open an agency about January 1 near Spring and Fourth streets, to be in charge of Kimmel Bros., of Dayton. Frank Corbett, representing the Maxwell in central Ohio, will move about December 1 to a new salesroom which will be located at 58 East Spring street.

AUTOS INCREASING IN BLUE GRASS CITY

LOUISVILLE, KY., Nov. 8—The automobile business is having an awakening in this city. Heretofore Louisville has been very slow to buy cars, and its prominence as a distributing center has been due to the manufacturers' distribution of territory; some of the local establishments handle the entire business of their companies south to the Gulf of Mexico. Things seem to be changing now, for at the same time that the manufacturers are making more local Southern agencies the people of the city are buying more cars. There are at present twenty-two branches or agencies in the city, representing fifty makers.

DETROIT'S LATEST TO MAKE PARTS

Detroit, Nov. 8—The Metal Products Company, just incorporated, with a capital stock of $200,000, all of which has been subscribed, is the latest concern to invade the local automobile parts field. The main product will be automobile axles, delivery of which will begin early next Summer.

The company brings to Detroit men of high standing elsewhere, who have been attracted to this city by the exceptional opportunities afforded in the line in which they have embarked. E. E. Keller, president of the new organization, was a former vice-president of the Westinghouse Machine Company, and with J. H. Hunter came here from Pittsburg three years ago, establishing the Detroit Insulated Wire Company. With them in the new company are W. F. Evans, recently with the Westinghouse Company, and H. L. Barton, both of Pittsburg, and E. E. Arnold, who comes from Buffalo. Mr. Barton is vice-president and Mr. Evans manager of the plant.

ATLAS PROTESTS VANDERBILT DECISION

First place in Class 2 in the Vanderbilt Cup race has been claimed by the Atlas Motor Car Company for its entry. Class 2 is for cars rated from 301 to 450 cubic inches piston displacement, and was combined with Class 1, contesting for the Vanderbilt trophy itself. In addition a special trophy was offered for the winner in Class 2. This trophy was not awarded on the ground that no car had finished in that class; Chalmers-Detroit No. 7 completed but 19 laps, and the Atlas was running on its fifteenth when the race was called. The Atlas company contests the decision not to award this trophy, and claims it, if awarded, on the ground that the Chalmers-Detroit was out of commission at the time the race was called. The Atlas company has filed a formal protest with the Motor Cups Holding Association.

ANDERSON BUYS ELWELL-PARKER COMPANY

Detroit, Oct. 30—A deal of consequence in the automobile world was consummated this week when the Anderson Carriage Company, of this city, purchased outright the Elwell-Parker Electric Company, of Cleveland, a large manufacturer of electric automobile motors. The Elwell-Parker Company is capitalized at $400,000 and employs several hundred men.

The Anderson Carriage Company by this move has placed itself in a position of greater independence as regards its materials. With the absorption of the Cleveland concern it will manufacture practically every part of its product, the Detroit Electric, with the exception of wheels and tires.

Pretty Good Trip for an Eleven-Year-Old Pilot

"Piloted by little eleven-year-old Archie Smith, a big Stoddard-Dayton touring car swung into San Antonio yesterday afternoon, on the completion of a long overland trip from Denver, a distance of 1,385 miles by the speedometer."—San Antonio Daily.

BOSTON MOTOR CLUB DISBANDS

Boston, Nov. 6—The Boston Motor Club, which was organized last spring in the main by some of the members of the Bay State Automobile Association, dissatisfied with the conduct of motoring affairs by that organization, is going out of existence. The officers and directors of the Motor Club, after deciding that there is no field for another motoring club similar to the Bay State, and that that organization fills the field satisfactorily, voted to liquidate the affairs of the Motor Club. Consequently the members have been given the option of receiving back their money, minus a small percentage used for expenses, or having the money turned over to the treasurer of the Bay State Association as payment for admission to that association. The expenses of the club have been small so only a small part of the original payments has been deducted. Many members of the Motor Club have already applied for admission to the Bay State Association.

NEW RECORDS EXPECTED AT NEW ORLEANS

New Orleans, Nov. 8—Work began to-day on the mile race track at the Fair Grounds in preparation for the Good Roads automobile race meet to be held November 20-21. The course will be scraped of all its present top soil, until only the "buckshot" black loam is left. Then that will be oiled and made perfect for such record-breaking fast time as was made over the course last February. Arrangements were made last week with Capt. W. H. Hardee, city engineer, for the use of the city road repair forces for this work. This meet is being held by the New Orleans Automobile Club in connection with the first Louisiant Good Roads Convention, called by Gov. J. Y. Sanders, the New Orleans Progressive Union and the automobile club.

George Robertson, winner of the 1908 Vanderbilt Cup, the 1908-09 Fairmount Park races, the Lowell National Cup and two 24-hour Brighton Beach races this year, will compete. One of the certain starters against Robertson will be Lewis Strang, his oldest rival, who will drive the Vanderbilt Cup race Fiat.

QUARTERLY DIRECTORY BIGGEST EVER

With the quarterly issue of the *Automobile Trade Directory* dated October, the publishers of this excellent and very handy work have reached a point where further increases will be sure to result in the division of the volume into two parts. In the October issue, just off the press, the 1 1-2-inch thick volume includes some 40 or 50 pages of additional matter.

This added amount of space is divided about equally between the alphabetical lists, which have an increase of 22 pages, and the geographical section, which has the rest. This latter feature, introduced in the July issue, has proved of such sterling worth that it will be retained for all time. The arrangement of the subject matter is about the same as before, access to it being facilitated by three indices, located in the front of the book. These are: the index to advertisers; index to classifications, and index to tables and data for engineers.

Although the latter, as the name would indicate, are primarily for engineers, much of it is such as would be constantly referred to by every one. Thus, every one is interested in the horsepower of automobile engines and ready means of figuring out the same—six pages are devoted to this subject. So, too, with the matter of speeds, not everyone can figure these out quickly, yet everyone wants to know about speed—six pages of handy tables are given over to this subject.

Over and beyond all this, the real purpose of the directory is to furnish complete and accurate lists of the manufacturers and dealers in different lines of business closely related to the automobile business. In this, there can be no question either of its thoroughness, the care with which it is compiled and edited making for extreme accuracy. It is published by the *Automobile Trade Directory*, Inc., at 231-241 West Thirty-ninth street, New York City.

On the Way from Uniontown, Pa., to the Mountain's Summit

Party with 42-horsepower, six-cylinder Franklin touring car, making the climb from Uniontown. The rise is 1,400 feet in a distance of three miles

Suit to Protect Cadwell Patent—Action has been instituted against the Rapid Safety Company, of New York, for alleged infringement of patent on an automobile cushion tire granted to Edwin B. Cadwell, and licensed exclusively to the Swinehart Clincher Tire & Rubber Company, of Akron, O. The infringing tires in question were manufactured by the Motz Clincher Tire & Rubber Company, also of Akron. The Swinehart Company, through its legal representatives, have notified the trade in general that it is its contention that any cushion tires having recesses in their sides, and presenting an unbroken tread surface, is an infringement of the said Cadwell patent, and that persons buying, dealing or using same will be held as infringers by the owners of said patent.

Making Tires for Aeroplanes—Taking time by the forelock, the Hartford Rubber Works Company has brought out a line of pneumatic tires especially designed for aeroplane use. These are made in three weights, known by the trade names of "Aviator," "Aeroplane" and "Aeronaut," for light, medium and heavy machines respectively. These tires are single-tube, and differ from bicycle tires principally in their sizes, which range from 18x1 1-2 to 28x3. In the construction of these tires it is claimed that the conditions under which they work have been carefully studied, with the view of obtaining great resiliency, together with the ability to withstand the shocks of alighting.

Japanese Visit Auto Factory—When the members of the honorary commercial committee of Japanese merchants, financiers and legislators visited Syracuse, N. Y., on their trip through the United States one of the points visited was the factory of the H. H. Franklin Mfg. Co. The party was shown the various operations in the making of the Franklin car, from the manufacture of the smallest parts to the finished machine. One of the developments which the members of the party expect as a result of their trip is an increased use of autos in Japan.

Mitchell Spreading Abroad—In the year of its organization, 1904, the Mitchell Motor Car Company built eighty cars, and a steady yearly increase has brought the output in 1909 to 2,500. Cars have been shipped to the Philippine Islands, South America, Australia and several other foreign countries, and the Mitchell catalogues are printed in French and Spanish as well as in English. Recently, also, a branch has been established in Paris at 20 Rue de Tilsitt, and in London, and an exhibit will be maintained at the Olympia Show.

Reo Challenges Tourists—R. M. Owen, who drove the new four-cylinder Reo in the New York-Atlanta good roads tour, has challenged the other perfect-score cars to submit to a technical examination to determine the real winner. Each car, after checking out at Atlanta, is to be delivered to a comimttee headed by Referee Scarritt, to make an examination under rules which it shall itself make. Repairs or replacements made on the route, or which may be necessary to restore the car to perfect condition, are to be charged against each.

Seven Molines in Kalona—The Moline Automobile Company has received a letter from J. W. Southwick, of Kalona, Ia., telling of his experiences with his Moline Model M. According to Mr. Southwick, there are seven other Molines in his neighborhood, all in the hands of inexperienced farmers, and all are giving perfect satisfaction. He further says that during the several months he has had the car he has had no expense for repairs. This seems to vindicate the Moline Company's policy of devoting especial attention to the country trade.

Toledo to New York Overland—Seven hundred miles through sand and mud in 40 hours' running time is the record of an Overland runabout driven by George L. Riess, the New York agent for the Willys-Overland Company. The trip was made on the spur of the moment, a new car just from the factory being used, without any special preparation. The trip from Toledo to Cleveland was made in 4 hours 5 minutes, over roads in some places deep in sand. The next day's run was to Westfield, N. Y., 6 hrs. 30 min.

Morgan Trucks Increase Stock—The capital stock of the R. L. Morgan Company, of Worcester, Mass., was increased at a recent meeting of the stockholders to $1,000,000, of which half is 7 per cent cumulative preferred and half common. This follows on the big South African contract recently made; the company, altogether, it is said, has signed contracts for 121 trucks. One trial order has been received from the Curtis-Blaisdell Company, of New York, which may result in the ordering of 30 or 40 more. The increased capital will enable the company to make all its own parts.

Badger Wins Patent Case—The Badger Brass Mfg. Co. announces a decree sustaining patent No. 841,799, granted to Geo. Maris and Besnard, Maris & Antone, of Paris, January 22, 1907, for improvements in automobile lamps. The suit was brought against Herman Saxon in New York City and the usual perpetual injunction was granted against him and his agents.

Moon Tours in Texas—E. J. Moon left the St. Louis factory recently for Texas, taking with him one of the first 1910 Moon Thirties. He will make an extensive trip through the State by road, winding up at San Antonio. The object of the tour is of course to demonstrate the adaptability of the small car to the roads found in that part of the country. The Moon output for the coming season is estimated at 1,500 cars, an increase of 100 per cent over last year. Each car receives a 220-mile road test.

Lexington Stays in Lexington—Lexington and Georgetown, Ky., capitalists, represented by A. G. Morgan, have secured an option on the controlling interest of 340 shares in the Lexington Motor Car Company, held by G. D. Johnson, of Connersville, Ind. Mr. Johnson had planned to remove the Lexington plant to Connersville, and the plan to buy his stock was formed by the Lexington Commercial Club to keep the plant in that city. The option sets the purchase price at 115 per share.

Portola Race on Fisk Tires—The Pope-Hartford driven by Jack Fleming, which won the 258-mile Portola race, at Oakland, Cal., in 238 minutes, was equipped with Fisk tires. The car made the run, at an average speed of 64.7 miles an hour, without any tire trouble whatever on the road. Three of the car's shoes were changed near the end of the race as a precaution, but the other shoe and its tube went through the whole race and finished in good condition.

Friction-Drive Patent Suit—The Cartercar Company, of Pontiac, Mich., has commenced suit against J. B. McIntosh, as agent, and the Buckeye Mfg. Co., of Anderson, Ind., maker of the Lambert, as principal, for infringement of the Carter patent, No. 761,146, dated May 31, 1904. Proceedings were begun in the United States Circuit Court at Detroit through Parker & Burton, who have been prominent in the litigation over the Selden patent.

New Owen Thomas Company—Capitalists controlling the Wisconsin Engine Company, at Corliss, Wis., have purchased the patents and rights of the Owen Thomas Motor Car Company, of Janesville, Wis., and will engage in automobile manufacturing. The holding company is capitalized at $500,000. No announcement of the location of the prospective factory has been made, but it is expected that it will be near Corliss.

Goodyear Gets Big Contract—What is said to be the largest tire contract ever made in this country was made recently between the Goodyear Tire and Rubber Company and the Buick Motor Company. It is estimated that the Buick Company will make 40,000 cars during the coming season, and Goodyear quick-detachable tires and rims will be their standard equipment.

Ajax, New York to Atlanta—The latest performance of Ajax tires was on the New York to Atlanta tour, in which five cars had this equipment. Not a single Ajax casing was replaced during the tour, and the twenty tires only had three punctures. Every casing, it is said, was in condition when it reached Atlanta to turn around and make the trip back to New York.

Standard Roller Bearing Officers—At the meeting of the directors of the Standard Roller Bearing Company in Philadelphia Lenox Smith was elected president, Osgood Field vice-president, R. S. Woodward, Jr., general manager, and W. M. Baldwin secretary and treasurer.

IN AND ABOUT THE AGENCIES

Great Western Agencies—The Great Western Automobile Company, of Peru, Ind., announces that it has made contracts with the Sheldon Automobile Garage, Sheldon, Ill.; J. F. Metzler, Helena, O.; C. A. Kenney, Nicholasville, Ky.; H. O. Vogel, 1610 South Main stret, Los Angeles, Cal.; Geo. H. Peddle, Perry, N. Y.; the Albert Sterne Motor Car Company, St. Louis, and O. B. Shutt, Peru, Ind., all of whom will handle the Great Western exclusively.

Apperson, Philadelphia—The branch-house habit struck the Apperson plant in Philadelphia last week, and hereafter the car will be represented in the Quaker City direct from the factory, with Alexander M. Benson, formerly head of the local agency, as general manager and Harry Jones, from the factory, as his assistant. There will be no change in location, the present quarters at 620 North Broad street being admirably adapted to the purpose.

Palmer & Singer, Philadelphia—George Parker, manager of the Philadelphia agency of the Palmer & Singer car, has secured the corner section of the new concrete building now in course of erection at Broad and Callowhill streets, where he will open well-equipped quarters soon after the first of the year.

Studebaker, Brooklyn, N. Y.—The Studebaker Company has chosen the Carpenter Motor Vehicle Company to act as its representative in this borough of the metropolis, with quarters at 1239 Fulton street.

Parry, Velie and Demot, Toledo, O.—The Norris-Toledo Motor Sales Company has been formed in this city to represent the Parry, Velie and Demot runabout, with salesrooms at 623 Madison avenue.

Stoddard-Dayton, Harrisburg, Pa.—The Cox Automobile Company, the local agent for the Stoddard-Dayton, is now located in its new building at 23 South Fourth street.

Empire "20," Philadelphia—The Motor Supplies Company of Philadelphia, which a fortnight ago secured the local agency for the Empire "20," has taken over the old Acme quarters at 608-610 North Broad street.

Autocar, San Francisco—Walter Morris, who is the local representative for the Autocar, is now installed in his new salesroom on Golden Gate avenue.

Lexington and Parry, Providence, R. I.—The Nock Auto Company, of this city, now represents the Lexington and Parry cars, with salesrooms at 486 Broad street.

Ford, Streator, Ill.—The Pontiac Motor Car Company, the latest addition to the local field, will handle the Ford and in addition make a car of its own.

Martin Commercial, Philadelphia—D. P. S. Nichols, Broad street above Vine, is handling the Martin Commercial delivery car in the Quaker City.

PERSONAL TRADE MENTION

P. J. Dasey, who has been identified with the automobile business since its inception, and who for several years past has been eastern manager for the Motsinger Device Manufacturing Company, has been appointed sales manager of that concern and is now located at the factory at Pendleton, Ind. R. S. Bryan has been appointed eastern manager, with his office at 31 West Forty-second street, New York City.

J. C. Matlack, who has been vice-president and manager of the Michelin Tire Company, of Milltown, N. J., since its inception in 1907, has resigned his position with that company. No announcement has been made of Mr. Matlack's future plans nor of his successor.

N. Lazarnick, the photographer, has removed his place of business from 29 W. 42nd street, New York, to more commodious quarters at 246 W. 42nd street, on account of increased business and the desire to include other and broader fields of photography.

Flavius Sudrow, formerly secretary and treasurer of the National Battery Company, has secured the exclusive sales rights in the United States for a device known as the American Auto Heater, and is located at 15 West Swan street, Buffalo, N. Y.

C. Royce Hough, formerly with Fickling & Company, New York, has returned to Washington, D. C., as sales manager of the General Motor Company's distributing branch for Maryland, Virginia and North Carolina.

Jesse Froehlich, managing director of the Benz Auto Import Company, sailed for Europe on the *Amerika*. He will visit the London automobile shows and then go to the Benz factory at Mannheim, Germany.

Stanley A. Allen has left the Packard Motor Car Company of New York to accept the position of general manager of Fickling & Company, of New York, manufacturer of auto bodies and tops.

F. R. Bump, sales manager; J. E. Walker, advertising manager, and R. H. LaPorte and L. E. Hoffman, salesmen, are representing the H. H. Franklin Mfg. Co. at the Atlanta show.

GOODRICH NEW YORK BRANCH MOVES

The B. F. Goodrich Company of New York has moved its entire business from 66 Reade street and 1625 Broadway to its new twelve-story building at 1780 Broadway, which has been illustrated in these columns. Commodious reception rooms have been provided for the accommodation of visitors. W. H. Yule remains in charge as manager and H. C. Miller superintends the tire department.

A NEW METROPOLITAN AGENCY

The Colt-Stratton Company has been formed to handle the Cole "30" and the Paige-Detroit roadster in New York City and vicinity, and is located at Broadway and Sixty-eighth street. William L. Colt, ex-president of the Cleveland Motor Car Company, and later advertising manager of "Hampton's Magazine," heads the concern. Harry L. Stratton, vice-president and treasurer, was formerly with the Amalgamated Copper Company. The Paige-Detroit is a newcomer from Automobile City.

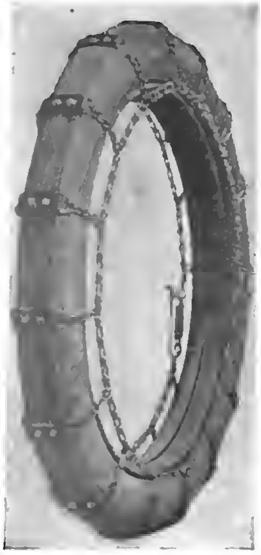
PACKARD'S NEWARK, N. J., STORE

NEWARK, N. J., Nov. 8—The Packard Motor Car Company of New York has opened a new salesroom on Branford Place, Newark, which it will operate as a branch office. The building is fireproof, of reinforced concrete and brick construction. The main office is finished in mahogany in simple style. The main floor contains a stock room, where a complete supply of parts for all models of Packard cars is maintained, and a repair department. L. Fitzgerald, formerly of the New York office, is in charge.

New Salesroom of the Packard, on Branford Place, Newark, N. J.

Information for Auto Users

Extra Hard Anti-Skid Device—The latest anti-skid device to be placed on the market with the coming of winter is known as the Traver Non-Skid Device, and is manufactured by the Philip Traver Mfg. Co., Far Rockaway, N. Y. The manufacturer is so confident of the quality of this device that he guarantees it to run 1,000 miles without showing any appreciable wear. The non-skids are curved pieces of doubly hardened steel spaced around the tire. The edges are flared, both to increase the non-skidding properties and to make impossible the cutting of the tread of the tire. A strong spring attachment on the side members of the device prevents the chains from coming loose, rattling, and losing their efficiency. This spring device is operated by a simple wire lever, so constructed that the non-skid pieces are held firmly and evenly against the surface of the tire. This is one of the best features of the Traver product.



TRAVER NON-SKID DEVICE

In addition to the non-skid device made up as one chain, the company manufactures what it calls a sectional non-skid device. This utilizes the same principle as the complete chain, differing in that each piece is put on individually and held in position by rubber-guarded chains which fasten to the spokes. A wheel may be equipped with as many or as few of these as conditions require. All of the tread pieces which take the wear are doubly hardened by a secret process, the result being a surface so hard that a file will not scratch it.

New Paste Makes Valve Grinding Easy—A new substance recently put on the market with the idea of saving motorists labor, material, and money in valve grinding, is being manufactured by the Victor Auto Supply Mfg. Co., 42 West Forty-third street, New York, and is known as Vasco Grinding Compound. In the past, many car owners have experienced repeated trouble with valves that have been improperly ground by the old method, employing oil and emery. Aside from this being an expensive process, it has been found by experts to be highly injurious in many cases. Vasco Grindine has been orepared to eliminate the dangers of emery, and machinists who have tried it find that it does so most efficiently. The abrasive in the compound is an electro-chemical product and was selected over all others owing to its extreme hardness, sharpness, and temper. The binder used has a high viscosity and produces a smooth, even surface. Conveniently put up in collapsible tubes, both coarse and fine, the preparation always remains at the right consistency. One of the chief virtues is that it does not waste away or drop into the cylinder during the process of grinding. It also cuts more rapidly than any other compound.

What's in a Name?—The old saying, "What's in a name?" will be clearly proven as to truth or falsehood in a few short months by one New England concern, the Dover Stamping & Mfg. Co., of Cambridge, Mass., which is now asking the public to give a name to the latest output of the factory. This is an improved funnel, which not only is effective as such, but a great fuel saver in that it is so made as to automatically cut off the outflow of gasoline when the top level is reached. In this way the surplus poured into the funnel may be poured back into the fuel can and saved. The way in which this is accomplished without complications is interesting. Within the funnel is a ball, which is held up off of the outlet hole when the funnel is in use, but as soon as the funnel is raised this ball drops back and covers the hole so that no more liquid can flow through. Those who have had experience with the overflow running all over the floors, seats and other parts of the car will appreciate this new device at its full worth. And still the contest is open for the $50 which will be paid for a good, suitable name. The cut is partly sectioned and shows construction.

DOVER (NAMELESS) GASOLINE FUNNEL

New Removable Rim and Tire—To be able to make a tire change on the road in from two to three minutes, and that with little or no exertion and without getting the hands dirty, is the function of the removable rim. Among those put on the market with this idea in view is the new rim brought out by the Empire Tire Company, Trenton, N. J. This newest addition to the rim family, as shown by the two figures on this page, has a clincher rim, which bolts to the wheel by means of eight bolts. Only six of them, however, must be loosened to make a change, the bolts on each side of the valve being left tight at all times. When the bolts have been loosened the lug is turned over to present the short side to the tire and rim, which may then be pulled off. The new Empire tire, which will be exhibited at the Atlanta show for the first time, has an unusual tread. This has been given the name of "checkered" by the makers, as that indicates the shape and condition of the raised tread portion. The tire is of the same heavy, moulded construction as all other Empire tires, but the new addition, the checkered tread, renders the tire non-skidding. The showing of this new tread at this show, just at this time, when winter is coming on, is particularly appropriate, as this is the time when automobilists are interested in anti-skidding devices. The tire with a tread of this sort is a big advance over the removable and consequently bothersome type. This tread is seen in the illustration to be raised above the surface, so that the "checkers" are really added material.

THE AUTOMOBILE

Wide Track, Plenteous Entries, and Generous Attendance, All Made for the Success of the Big Meet

ATLANTA AUTO WEEK AWAKES SOUTH

ATLANTA, GA., Nov. 13—The show is ended, the races are over, and the tourists are wending their varied homeward ways. Atlanta's automobile undertaking was crowned with gratifying success, and substantial results have come to the industry, to the buyer of cars, and to the man who enjoys speed contests, not forgetting the greater number who are interested in the building of roads so that they can more thoroughly enjoy the most economical and pleasurable necessity of the age.

It needed a National show to awaken in great degree the interest of the South, and this hustling city has met the requirements of the situation with commendable enterprise and a unanimity of effort which contained only minor mistakes. The first exhibition of 1910 cars in the new Auditorium-Armory attracted large attendance, though it is unquestionably a fact that a plethora of racing caused the out-of-town visitors to give the show less attention than would have been the case had there been less of the spectacular on tap to occupy their time.

To those who had never seen automobile contests, the events on the remarkable speedway presented a magnetism which could not be resisted, and even the old-timers enthused over some of the notable contests of the week. Managers Miles and Reeves expressed satisfaction when the reports began to reach the

Knipper's Chalmers-Detroit, Winner of One of the Important Events, in Full Flight

Aitken's Six-Cylinder National Was a Notable Performer

executive offices that the exhibitors were doing much business in the way of establishing Southern agencies, and also securing in many instances a considerable number of individual orders.

As to a National show in Atlanta another year, that question will have to be answered by the National Association of Automobile Manufacturers, when a summation of the entire exhibition is available.

The various tours into Atlanta from all over Georgia added immensely to the good roads campaign which is being vigorously pushed throughout the State. A thorough realization of this only comes through touring into the country districts where a frequent scene includes the stripe-suited convicts healthily digging away at Mother Earth, from which task they desist only long enough to importune the passing tourist for some change for the ever-needed tobacco. The New York-to-Atlanta tour of the New York *Herald* and Atlanta *Journal* set the ball a-rolling, and this was supplemented most successfully by the half-dozen runs into Atlanta, promoted under the auspices of the Atlanta *Constitution*. With the other Atlanta paper, the *Georgian*, an ardent advocate of convict labor on the roads, it is to be seen that the press of the city is united in its espousal of the automobile and the sequent building of highways.

During the week there have been numerous dinners and an abundance of entertaining, so much so that the recipients lost sleep in generous quantities. It might be mentioned that Georgia is a prohibition State, and the favorite beverage in Atlanta is Coca-Cola, the production of which supplied the basis of the Candler millions. That alcoholic nourishment was obtainable in Atlanta, however, was discovered in due course of time by those who sought such alleviation of thirst.

Of course, there were the usual first sales of cars, but no concern reported that its entire output has been sold at the show. This statement will be reserved, as in previous years, for the forthcoming exhibitions in New York City. All around it is the concensus of opinion that at this time the Atlanta show was more than worth while, and the resultant good will offset by a comfortable balance any expense to which the exhibitors were subjected in thus opening up a section of the country where good roads progress will materially increase the sale of automobiles.

What the Racing Summary Shows—Medium-priced American stock cars have again demonstrated their marvelous speed capacity. No one would have imagined a few years ago that cars selling to every-day customers for from $1,500 to $3,000 could

CONDENSED SUMMARY OF THE ATLANTA SPEEDWAY RACES, NOVEMBER 9 TO 13, 1909

Distance	Winner	Time	M.P.H.	Second	Time	Third	Time

be stripped, brought out on a track, and made to show 60 to 75 miles an hour for 2000 miles at a stretch. Admitting to the fullest degree that speed is not the only thing to be sought for in automobile construction, this remains at once a demonstration both of the power and the reliability, in the face of the hardest of usage, of the machines in question.

There can be no doubt, either, of the value of these races to the manufacturers who have consistently participated in them, from the engineering as well as from the advertising point of view. Their 1910 models may be expected to show the influence of the experience thus gained, not in ways patent to the casual observer, but nevertheless important in the final performance of the car.

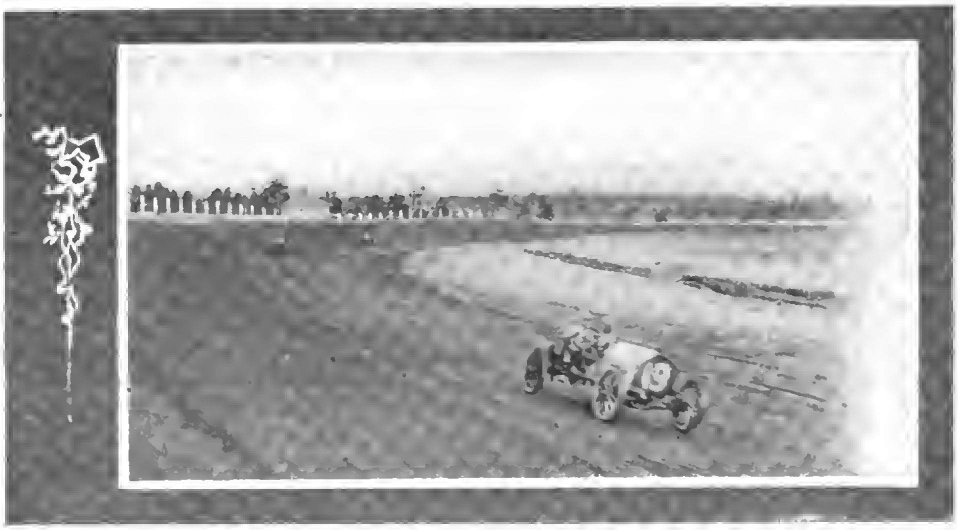
The summary shows that in the largest class the National, Apperson and the Rainier each made away with one event, while the Fiat, which was driven by Robertson, took two. In addition National scored three second places, and Fiat one, while Apperson got three thirds. Disbrow's performance of 200 miles in 2.53:48 was creditable.

In the class for cars with a piston displacement of from 301 to 450 cubic inches displacement National and Buick split even, each with two victories. Chalmers-Detroit was the heaviest runner-up, garnering no less than three seconds and four thirds, which, scoring by points as a track-meet is scored, would put them ahead of the other two.

Marmon proved the leader in the 231-300 inches class, scoring two firsts to the Buick's one; it must be admitted, however, that in one of these, a handicap, the Marmon was given far too great a distance. Marmon also took one second, and Chalmers took two seconds and two thirds. The baby Chalmers had it all their own way in the smallest class, and the real racing was between Matson and Knipper. In this Knipper had the better of it, but only after several of the hottest kind of races. Nelson squeezed his Buick in for two thirds.

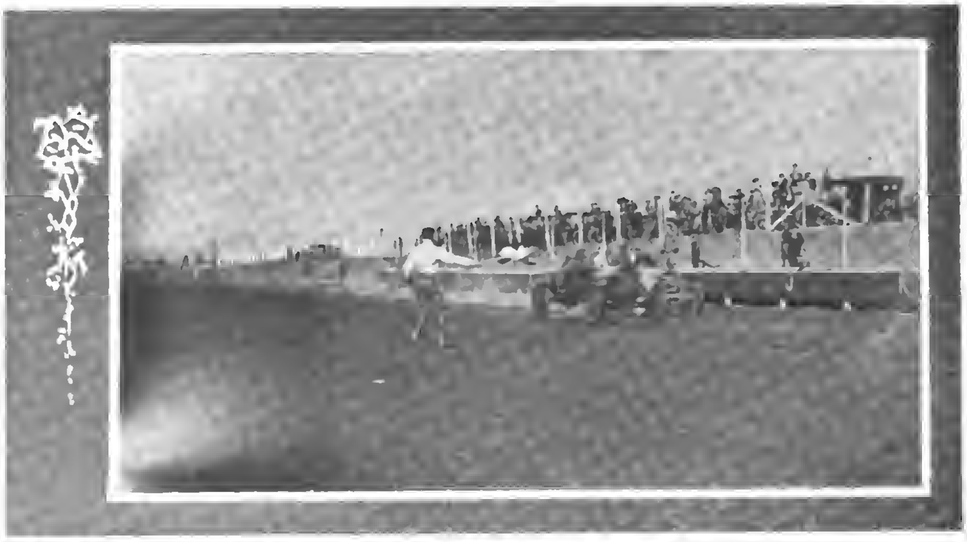
In the free-for-alls Strang and his big Fiat had it all their own way, at least on the shorter distances. Barney Oldfield, who has often found easy picking with his Benz Grand Prix racer, had to admit himself outclassed. It was a case of "defeated, but not dishonored," for the relative powers of the two machines left no doubt as to the outcome. Incidentally, Michelin tires scored a goodly percentage of victories.

The twenty-mile handicap for New York-Atlanta tourists was a particularly interesting event, for it showed the possibilities of cars which were "stock" in the strictest sense of the word. All of these machines had of course to be geared low enough to take the hills and bad roads met with on the way, but nevertheless Stoecker drove his Benz over the twenty miles in 20:32, close to mile-a-minute speed.



As the Cars Rounded Upper Turn They Decreased Speed

Especially Well Equipped Were the Pits for Rapid Work



Harroun's Marmon Demonstrated Its Ability Repeatedly

STORY OF THURSDAY'S RACING

Atlanta, Ga., Nov. 11—If, as the dictionary alleges, "recrudescence" means the "breaking out after temporary abatement or suppression," then the recrudescence of Robertson was certainly the feature of the Speedway races on Thursday. Up to that day there can be no denying that Robertson was well suppressed. His Fiat was new and not tuned up, and though it showed symptoms of speed, it never really broke out with it all over.

But Thursday Robertson arrived—twice in fact. The first time was in the 10-mile stock chassis race for cars of 600 cubic inches displacement or under. Five cars started in this and four finished. But it was all Robertson. He was away first and finished the same, some three-quarters of a mile or more ahead of Jack Aitken in the No. 3 National, of lesser horsepower it should be said. Robertson came again in the 10-mile handicap, in which he figured as the scratch quantity. The handicaps were a joke to Robertson, though he was some time in demonstrating it.

The day's card opened with the long race, a 120-mile stock chassis affair, 231 to 300 cubic inches piston displacement, for the Atlanta Automobile Association trophy and some additional trinkets in the way of 1,050 gold dollars divided into three prizes.

According to a careful reading of the form charts Chevrolet was a certain winner over a field made up of Ray Harroun in a Marmon, Joe Matson in a Chalmers-Detroit, and Charley Basle in a Renault. The Buick ran for a good two dozen miles, opening up an awful lead. Then something went wrong with a valve. Chevrolet stopped on a turn and tinkered awhile, and then came back to the pits and tinkered some more. Then he tinkered a little while longer, and then he ran some. Finally he drew up in front of the pit and with the assistance of a hammer demolished much of the top of one cylinder, whittled out a wooden plug to fill the resulting hole, hammered it in and went on after third money.

By that time the Marmon had a defeat-proof lead and the Chalmers was second, but the Renault was no very excellent third, and the Buick, running on three legs, went after it. It was a game chase, and one that had the pit men cheering and shouting; but, though Chevrolet could pick up 10 seconds to a lap, he could not overhaul the Frenchman and his French car, and Basle finished third, taking the first money of what has been an unlucky meet for him. Whereupon he bought a bottle of lemon soda and a bag of chocolate creams, and, sitting in the shade of a pit wall, celebrated copiously.

The winning Marmon made the 120 miles in 109:26:94. Of course, there was no Indianapolis record to check this against, but when Harroun finished his one-hundredth mile he was 1 minute 33 seconds ahead of his Indianapolis time for that distance.

The second race run was a 20-mile handicap, which was one wild, grand scramble, a veritable motor melée, in which L. A. Disbrow's Ranier proved the best scrambler. There was a desperately narrow escape as the cars were lining up. The Matheson, which was slated to make its Atlanta début in the race, was the last car to come down to the line, and it came with a rush. Neil Whalen tried to put on the brake when the line was nearly reached, but it did not stay put. Whalen yanked his car one way and then the other, slowing it down by the skidding method, and finally headed for a very narrow hole between the pit fence and the inside car of the machines lined up. In this opening were two useful officials, one of which jumped one way and the other the other, just in time to escape the big six-cylinder, which reeled through the opening and out safely on the other side. Before the car was well stopped Starter Wagner and Referee Pardington hove alongside, and began telling Whalen just what sort of a driver they thought he was, which, being completed, they sent him back to the garage to repair his brake, starting the race without him.

A 10-mile event open to amateurs for the Southern championship followed, and John Rutherford in a Stearns was a winner by a safe margin.

At this point there was an "extra." Strang's 200-horsepower Fiat was driven on the track, and with it was the original Haynes runabout, with Elwood Haynes in the driver's seat and Asa Candler, Jr., beside him. The two cars were driven down in front of the judges' stand, photographed, and then the Haynes was driven off the track while Strang went an exhibition two miles from a flying start in 1:21:51.

In event 13, which was next, another Indianapolis (and likewise American) record was demolished. This race was at 20 miles for cars of 301 to 450 displacement and a field of a half dozen faced the starter. For the first lap the ones you could have covered with the proverbial blanket were the two Nationals, a Marmon, and Dingley's Chalmers-Detroit, in the order named. At the end of the next lap it was the same, except that Dingley's Chalmers had nosed out Lorimer. The next laps the two National changed places and the Chalmers cars likewise "swapped." On the fourth time around the Kincaid National went out of business, but Aitken's car continued steadily in the lead, except in the fourteenth mile, when Lorimer made his last desperate drive and for a few seconds led the procession. In that one lap he shot his bolt and dropped back to third, while Harry Stillman's Marmon worked up into second place and stayed there until the end.

It was a grand race. For mile after mile the three or four leaders were separated by inches only, and the crowd, demonstrative always, was wild in its enthusiasm.

The only other event not already described was the seventeenth, a 4-mile stock chassis affair, for cars of 161 to 230 cubic inches displacement. In this race the two little Chalmers finished "one-two," with Joe Nelson in a Buick third and an E-M-F fourth. The time was 4:05:52. Summary:

120-MILE STOCK CHASSIS (231 to 300 Cubic Inches)

First Prize, Atlanta Auto Association Trophy and $600 in Gold; Second Prize, $300 in gold; Third Prize, $150 in Gold.

1	Marmon	Harroun	1:49:26.94
2	Chalmers-Detroit	Matson	1:57:22.92
3	Renault	Basle	2:09:15.20

20-MILE STOCK CHASSIS (301 to 450 Cubic Inches)

First Prize, Cup; Second Prize, Cup.

1	National	Aitken	16:42.76
2	Marmon	Stillman	16:46.86
3	Chalmers-Detroit	Lorimer	16:49.63

The winner's time is a new competition record.

10-MILE STOCK CHASSIS (600 Cubic Inches or Under)

First Prize, $100; Second Prize, $50.

1	Fiat	Robertson	7:47.71
2	National	Aitken	8:22.87
3	Apperson	Harding	8:23.17

10-MILE STOCK CHASSIS (Amateur Drivers Only for Southern Championship)

First Prize, Cup; Second Prize, Cup.

1	Stearns	Rutherford	8:42.63
2	Buick	Oldknow	9:04.17

4-MILE STOCK CHASSIS (161 to 230 Cubic Inches)

First Prize, Cup; Second Prize, Cup.

1	Chalmers-Detroit	Matson	4:05.52
2	Chalmers-Detroit	Knipper	4:08.42

20-MILE FREE-FOR-ALL—HANDICAP

First Prize, $150; Second Prize, $50.

1	Rainier	Disbrow	(2¾ min.)	19:51.15
2	Marmon	Harroun	(2½ min.)	20:10.63
3	Marmon	Stillman	(2 min.)	20:23.41

10-MILE FREE-FOR-ALL—HANDICAP

First Prize, $150; Second Prize, $50.

1	Fiat	Robertson	(scratch)	8:39.08
2	National	Aitken	(32 sec.)	8:50.25
3	Marmon	Stillman	(32 sec.)	8:50.53

Fiat	Strang	1:21.51

THE EVENTS OF FRIDAY

Atlanta, Ga., Nov. 12—The Atlanta Speedway has had luck in its weather, in its entries and in a score of ways, but Friday there were horseshoes and rabbits' feet pinned all over the track. From the start of the meet any car could smash a steering knuckle, blow out a tire or lose a wheel going at absolutely top speed and not a soul would be even scratched.

But on Friday there were two accidents, either of which was calculated to kill a man or two, and yet, barring a scratched face, not a person suffered.

The first and most sensational accident happened in the morning—an accident that marked the passing of "The Merry Widow," the big Pope-Toledo racing car of ill repute and worse manners, which Asa Candler, Jr., president of the Atlanta Automobile Association, bought for use in the local races.

This car had showed its real class on the first day of the local races by back-firing when Louis Cliquot, its driver, was cranking and thereby fracturing his arm in three places. The car was then given over to Charlie Basle, who tinkered with it for a day, and then passed it on politely, but firmly, to Kilpatrick, who had come to Atlanta to drive a Hotchkiss, which went wrong and left him temporarily without an occupation.

Kilpatrick almost got the evil old craft in running order. He tinkered with it and nursed it along, and in the early hours of Friday's practice the old boat was running passably well. Then came the accident. Going at a good rate of speed the car rounded the first turn in good order and started into the second. As it did so the engine blew up. What gave way nobody knows, but a piece of steel from the engine went hurtling into the air, carrying the hood with it, and in a second the machine was beating itself to pieces and reeling up the track. At the head of the backstretch the "Merry Widow" headed for the outer rail, where there was a drop of 20 feet to the ground below. The fence straightened it out and it reeled back into the track, gave way all at once, threw the driver and mechanician high in the air and over the bank, turned a somersault, rolled over a couple of times, exploded mildly and then burned fiercely.

The miracle was that neither driver nor mechanician was hurt. It was only a matter of pacing to prove that both men were hurled nearly 60 feet from where the car threw them and that the drop from the track level to the ground below was 20 feet. And yet both men sailed this distance through the air and landed safely and with no damage done. The mechanician was not even scratched or jarred. Kilpatrick was slightly burned, but not otherwise hurt.

The "Merry Widow" burned fiercely, and it was nearly an hour before the flames could be sufficiently checked so that the wreck could be hauled off the track.

Strang, in his 200-horsepower Fiat, was the hero of another miracle. In the 50-mile free-for-all, while going at a good 80 miles an hour, the tread of his right rear tire came off. He shut off, slapped on the brakes, and managed to slow down his car to a moderate gait before the inevitable blow-out came.

The next accident, and the last one of the meeting, came later on in the 50-mile race. The two big Chalmers had kept the Apperson "Jack Rabbit" pretty well pocketed for a couple of laps, when Harding, in the last-named car, took a long chance. Motioning that he was coming between the two cars he slipped through a narrow opening and went out in front. His lead was short lived. As his car finished the first turn the right rear tire threw its tread; and Harding, foreseeing a blow-out, turned sharply into the inner rail. As he did his car skidded and the rear wheels went into the front of the Chalmers-Detroit driven by Lorimer. Both cars spun dizzily, smashed up a trifle, and came to rest without capsizing. Not a man was thrown from his car and the damage to the machines was so slight that the "Jack Rabbit" was running the next day, and the Chalmers could have been if it had been necessary.

Owing to the extreme length of the meet the fourth day's racing was notable largely for the small fields. There was really only one good race, and that was the 50-mile free-for-all.

If Louis Strang could have kept tires under his 200-horsepower craft there would have been nothing to it. He made the first 10 miles of the race in 7:18:21, which was way under the Indianapolis record for that distance. Then came the blow-out Strang retired, well knowing that his machine was not cut out for 50-mile performances on a track.

Then the race became a picnic for Robertson's stock "60" Fiat. Aitken's "40" National was always second, after Strang dropped out, and Stillman's Marmon came in a good third, pulling up from nowhere by steady work. The time of the winner was 40:14.02, which was well below the Indianapolis record of 44:31.2. In fact, the first four cars which finished were below the Indianapolis mark.

None of the other races was sensational. In Event 20 the only starters were two Chalmers, driven by Knipper and Matson, who circulated around the track in slow time. Event 21 was another picnic for Robertson and the Fiat. It was at 6 miles, and he romped home in 4:43.37 with Jack Aitken in the No. 3 National second and the Apperson third.

Aitken was the winner in the event for the 301 to 450 class at 12 miles in 10:07.65. It was not any runaway, however, for Dingley, in one of the Chalmers, gave stern chase and led on the fourth and fifth laps, only to be nosed out by a margin of less than two seconds.

The two-mile free-for-all, which was changed from a two-heats-in-three to a one-heat affair, was easy for Strang and the big Fiat. Robertson in the smaller Fiat made great time on the turns and seemed to have second place cinched, but Walter Christie, who had to take it easy on the turns, came down the stretch faster than ever car had done before and took second money.

The handicap, limited to contestants in the tours to Atlanta, was won by a Benz, driven by Ernest Stoecker. Summary:

24-MILE STOCK CHASSIS (161 to 230 Cubic Inches)

First Prize, $100; Second Prize, $50.

SATURDAY'S CONCLUSION RATHER MILD

ATLANTA, GA., Nov. 13—If it had not been for the 200-mile race for big cars the officials would have been hard put to it to scrape up enough entries to-day to keep things under way. Four days of hard, even if lucky, racing had put a few drivers and more cars temporarily out of the running. However, a good field was patched and scraped up for the long event, and the contest was not without spectacular features. It proved a revival of the good old tale of the hare and the tortoise, with the Rainier car, driven by Disbrow, in the rôle of the tortoise.

The Rainier, except for the winning of a handicap, had not had any luck. But in the 200-mile race for the wonderful City of

Atlanta trophy and $1,000 in gold it was the easiest kind of a winner. And, incidentally, the two Renaults, which finished third and fourth, both broke out of the non-winner class in the greatest event of the week. These cars ran through the 200 miles, with only one stop, and that for oil. The Rainier even bettered this. Not once in all the long grind did it hesitate, not a single time did it stop for repairs or supplies.

An even eleven cars started in the race—practically all the high powered machines that were in commission at the track. There were Robertson and Strang in stock Fiats; the Basle brothers in Renaults; Matson and Dingley in Chalmers-Detroits; the winning Rainier, the Apperson "Jack Rabbit," Stillman and Harroun in Marmons, and Chevrolet in a Buick.

In the natural course of events Robertson was the favorite. His Fiat was working marvelously, and if it could have kept going would have had the race won. All the heavy betting was on him. For 163 miles he was the leader of the race. This wily driver well knew that this race was not altogether with the swift. So he put a good lead to his credit, and then tacked to Disbrow's Rainier and hung on like grim death, accepting pace though his car had all the advantage in speed.

Then came the accident that caused the trouble. Whirling into the last turn his chain gave way. It was only the matter of a couple of links, but it cost him a half dozen laps and the race.

Two other prominent early contenders were Strang in his Fiat 60 and Chevrolet in a Buick. Strang was in the hunt for 28 laps, and then a series of mishaps which ended in the breaking of an oil pump case caused him to withdraw. Chevrolet made an even more brilliant race of it. For 42 laps his machine ran like an eight-day clock. Then the transmissions gave down in a heap; and, from a second-place position to a wreck at the pits, was the sudden transformation of his car.

The Chalmers team were good at the start, Dingley in particular staying well ahead of the ruck. But five days of hard racing had told on the cars, and both were eliminated before the race was well begun.

It took about 65 laps to get the race shaken down to a standing where even the experts could get a line on the finish. A broken spring put the Apperson out at about that point, and the Fiat of Strang had been driven slowly over to the garage and the five cars which were to finish were the only ones running. At that point Robertson was in the lead; the Rainier, which had pulled up from a chronic fifth, was second; and Charley Basle in his red Renault was third, with his brother in another Renault fourth. These two French machines had hung around the tail end of the procession when speed alone counted, but had pulled up when the reliability test had been applied.

Up to the 81st lap and nearly the end of the 82d the race has been a grind, with Robertson apparently the winner. Then came the accident to the chain and the race took a new aspect. The delay had killed Robertson's chances, but when he got under way again he was in third place and he set off like the wind to gain what distance he could. It took him 24 miles of furious driving to overtake Charley Basle and gain second place, and then he set off after Disbrow. It was a hopeless task, however. His only chance was that the Rainier pilot would have to stop, if only for a few seconds. So he took the chance and drove like mad. But never once hesitated the Rainier. As it had run at the start, it was running at the finish steadily and well. And it crossed the line a winner in 2:53:48.32. This broke the record of 3:24:13.4 made in Indianapolis; and, in fact, all four prize winners were comfortably under the Indianapolis record. The only other car that finished was Harroun's Marmon. It had no earthly chance and was dozens of miles back, but Harroun hung on in the hope that enough cars would drop out to put him in the prize money. But he missed being "placed" by just one position, finishing fifth.

The other races of the day were mediocre, owing to small fields and the fact that frequent clashes between all the cars had given the spectators a pretty good idea of how every race was to come out before it was even started. One of the few real contests was in the ten-mile event for cars of 231 to 300 cubic inches displacement. This was a see-saw affair in which the Buick, driven by A. Chevrolet, scratched up from third place to first and the Marmon, driven by Harroun, worked up from fourth to second; dropping a couple of Chalmers out of the prize money in consequence. The twelve-mile race for the 301 to 450 class was a procession with Chevrolet always leading, but the eight mile free-for-all handicap furnished a better contest. Aitken in his National was a winner, though at least three cars made it interesting for him.

The races closed with the long event and after it ended the crowds dispersed, not to assemble again until next Spring, when another meet is to be held. It is estimated that over 100,000 people attended the races and they proved a vast financial success. The $100,000 insurance that the Atlanta Automobile Association took with Lloyds against rain proved unnecessary, for barring a sprinkle on Wednesday the weather was beyond human criticism. Here is the summary of the last day's racing:

200-MILE STOCK CHASSIS (451 to 600 Cubic Inches)

First Prize, City of Atlanta Trophy (Which Must Be Won Three Times to Become the Property of the Entrant) and $1,000 in Gold; Second Prize, $500 in Gold; Third Prize, $300 in Gold; Fourth Prize, $200 in Gold.

METZ CAR IN 24-HOUR ENDURANCE RUN

WALTHAM, MASS., Nov. 13—The makers of the Metz car, which is usually sold unassembled, the parts being put together by the purchaser, gave one of their machines a strenuous reliability test recently. The run was over a five-mile course in the vicinity of Waltham, of which Glenn Curtiss in his motorcycle days once said: "For a speed contest this course is about the limit; but for an endurance run it's a dandy."

The car started at 5:45 P. M. One hundred miles were completed at 10:24; 200 at 6:19 A. M.; 300 at 11:07; 400 at 2:56 P. M., and 460 at 5:34. The gasoline consumption was 13 gallons 1 quart, and the oil consumption 6 quarts 1 pint.

The car ran with great regularity, making round after round without a stop. The only incidents were a puncture and the removal of some cotton waste which got into the inlet pipe.

Zengle's Narrow Escape—Len Zengle, who is now with the Pennsylvania factory at Bryn Mawr, Pa., was testing a racer last Saturday afternoon when a large touring car filled with women loomed up ahead. He deliberately steered his car up a high bank, hoping to dodge the trees, but one caught the Pennsylvania on the middle of the radiator. Zengle landed on a pile of leaves unscratched.

FRANCE FINDS NEW RULES OF THE ROAD IMPERATIVE

PARIS, Nov. 12—In addition to the international automobile regulations which have recently been studied in Paris, France is interested in bringing up to date her national laws governing traffic. The present set of regulations was drawn up in 1851, at a time, naturally, when automobiles were unknown, and when traffic was not as intense as to-day. Admittedly the laws need modernizing, and in order that this work should be done properly Louis Barthou, then Minister of Public Works, appointed a commission of experts, representing the automobile industry, road makers, horse owners, cyclists and the ministries of justice and public works, to draw up an ideal road code, which should be presented to the Minister of Public Works, and by him brought before the government for presentation to parliament.

The experts met last June, then again this month. In the meantime they had gathered together, in a classified form, all the road regulations of all countries. From this mass of regulations, some good, some bad and many indifferent, the experts will pick out the best and with them create an ideal set of laws governing traffic. Although the automobile men occupy a prominent position on the commission, the intention is to study the question from an even broader standpoint than that of motorists. The interest of all parties have to be considered from the standpoint of the foot passenger, the horse owner, the automobilist, and dwellers along the roadside. In addition the road builder will be consulted.

The commission is now in two sections, one of them studying the road itself, and dealing principally with the weights of vehicles that shall be allowed on the road, the type of wheels they shall employ, etc. The other section has the larger problem of creating laws for the regulating of traffic. It is very probable that the new code will adopt a free speed limit. At present official France is in contradiction with itself, for it has a maximum speed law of 18 miles an hour, which if rigorously applied would put every French automobilist into prison. Practically no limit is imposed, but there is always danger of an attacking party taking advantage of the legal limitation. What will doubtless be done will be to make the law as reasonable as its present application, which is no limit, but every man responsible for the accidents he may cause. This will also put a check on the mayors of little villages, who at present have the power to fix local speed limits varying from a walking pace to 10 miles an hour—but rarely have the courage to enforce them.

Lights on all vehicles will be a strong point of the new code. Where the maximum speed is less than 18 miles an hour, only one light will be required, but it must be of such a nature and placed in such a position that it will be seen as clearly from behind as from the front. Cattle and sheep driven on the road at night will have to show a light in a similar way, and it is more than probable that the same regulation will apply to troops and any considerable body of men marching together.

Another proposed improvement is that all cases of dispute between any stranger and a native shall not be tried before the local courts, but in the chief town of the department, corresponding to the capital of the State in America. Almost invariably in a dispute between an automobilist and another person the automobilist is a stranger to the district, or probably a foreigner, while his opponent is a native. The local judge has such strong local attachments that it is rare indeed that the stranger receives fair treatment. It is but natural that in case of a doubt the local judge should decide in favor of his townsman rather than of a stranger he has never seen and may never see again. At times, too, the automobile brings exceedingly important cases before exceedingly unimportant courts, the judge of which has not the experience necessary to arrive at a just decision. The transference of all such cases to the capital town would not cause much inconvenience to the natives and would assure fairer treatment to the automobilist.

Indications are that the new code will become law at an early date. Automobile touring in France has become so widespread, traffic is so great on all the main highways, that it is impossible to continue with a set of regulations brought into existence over forty years ago. What is needed is a set of regulations that will clearly define the duties and responsibilities of all users, that will make it impossible for the dare-devil chauffeur to endanger the lives of others, and equally impossible for the farm laborer to sleep in the bottom of his cart while his team wanders along at its sweet will. The highway has come to life and must have rules and regulations as clearly defined as those of the railway—and as rigorously enforced.

PRESIDENT TAFT O. K.'S THE SAVANNAH COURSE

SAVANNAH, GA., Nov. 13—President Taft, during his recent visit, gained the honor of being the first president of the United States to enjoy a ride around an automobile race course. He much enjoyed his circuit of the twenty-five-mile course on which took place the greatest automobile contest that was ever held. President Taft was greatly pleased with the reception in Savannah, and the ride was the best he ever had. When asked what he thought of the course, the President said: "This is the finest course that I have ever laid eyes upon, and you shouldn't let it be idle. Why, if we had it in Washington, we would have Grand Prize races every six months."

President Taft in Mayor Tiedeman's Packard "30"

The picture shows President Taft, Mayor George Tiedeman and Capt. Archibald W. Butts, in the rear seat, while James Sloan, Jr., the secret service man, occupies the front seat with the driver. The picture was taken in front of General W. W. Gordon's residence, where the President stopped. The car was the Packard "30" of Mayor Tiedeman.

NEW YORK "COPS" FOUND TOO FRIENDLY

Police Commissioner Baker of New York has decided that the bicycle policemen are getting too friendly with the chauffeurs who customarily pass on their beats. The "cops," it is said, are not averse to accepting an occasional ride, and in return look the other way when their acquaintances go by at a twenty-mile clip. As a result wholesale transfers have been made.

President Battey "At Home"

Tourists Leaving Louisville, Georgia, After the Prolonged Stop

HOW SAVANNAHIANS TOURED ACROSS GEORGIA TO ATLANTA

SAVANNAH, GA., Nov. 13—With thirty cars participating, the first endurance run from Savannah to Atlanta started from the DeSoto hotel on the morning of November 8 at 6.45 o'clock. As each car left a cheer was given, for more than five hundred saw the tourists begin their journey.

While traveling at forty miles an hour, Harvey Granger's big "6" Stevens-Duryea ran into a stump some nine miles out of Savannah, and had its front somewhat dented. Luckily for those in the car, it was thrown against a telegraph pole which kept it from capsizing.

The first greeting was received just after passing out of Chatham county, and it came from the road-making convicts. Brooklet was the first stop, and here hung a banner with the words: "Welcome to Brooklet." The next sign read "Burke County Line," and from here on the roads were so good that the cars arrived at Louisville two and a half hours ahead of schedule time. DeBorde's Buick lost two of its wheels near Waynesboro as a result of trying to get out of the way of a horse and wagon. Slight bruises came to the car's occupants, who were well enough to continue the trip after new wheels had been received from Savannah.

At Louisville, the former home of President Battey, a big dinner was awaiting the tourists, who were the guests of his old townsmen. The feast was bounteous and unique and the tourists found it hard to leave the fair ones who had served them so gracefully.

At Waynesboro came more luncheon, and again the contestants had no use for their money. At Sandersville the same treatment was repeated.

When about twenty-five miles out of Statesboro, Mayor Tiedeman was thrown from his Packard, and broke one of his fingers, besides sustaining a wrenched back. His finger was dressed by N. H. Van Sicklen, and he continued the trip.

When Milledgeville, the night stop, was reached, it was found that fifteen cars of the thirty had managed to keep in the front and check in.

All of the cars that checked in and those that broke down on the road and caught up after running all night, left Milledgeville the next morning at 8 o'clock. The send-off was one of the greatest the town had ever given to anybody. The cadets at the military school were drawn up in companies, and saluted as the contestants passed. On the steps of the old capitol where the ordinance of secession was passed, several hundred young ladies stood and waved American flags. When the cars passed the girls' normal school, the girls, who numbered way into the hundreds, stood in line and cheered each car as it went by.

Eatonton had a large banner carrying the words: "Welcome to Eatonton," which place was reached at 9.15. The sign "Newton County Greets You" introduced some of the best roads that had yet been passed over, and here the same "glad hand" was again extended.

Of the whole trip the best reception was received at Covington. The streets were roped off so as to allow the automobilists to go through to the place prepared for them at the court house, where dinner was served by a committee of young girls. The boys from Emory college also took part and gave a few college yells. While leaving Covington a slight accident happened. An E-M-F, driven by Adkins, ran into a Buick, driven by Youmans, and both cars suffered somewhat. A blacksmith was near at hand and soon had the cars running. The stay at Covington was stretched from forty minutes to 1 hour 55 minutes.

When it was heard that the party had reached Stone Mountain, a reception committee in three cars, headed by R. V. Connerat, met the party just below Decatur, in which were J. W. Hill, of Atlanta; Judge A. B. Moore, of Savannah, chairman of the commissioners of Chatham county; J. F. Lewis and C. Lochridge, of the Atlanta *Constitution*. The first car to reach Atlanta was the pilot at 4.30 o'clock, with twenty-five others following closely behind. The route then was out to the speedway and the clubhouse.

The following twenty-six cars out of the thirty starters finished the run: Stevens-Duryea, F. C. Battey; Stevens-Duryea, Harvey Granger; Packard, George W. Tiedeman; Chalmers-Detroit, T. A. Bryson; Packard, N. G. Browne; Stevens-Duryea, C. Barrow; White Steamer, F. F. Stacy; Stevens-Duryea, A. W. Solomon; White Steamer, L. H. Hilton; Buick, J. F. Toole; White Steamer, O. B. Martin; Crawford, W. C. Mahoney; Chalmers-Detroit, G. I. Taggart; Maxwell, W. H. Towles; Maxwell, R. Brockett; Cadillac, W. G. Austin; Cadillac, W. T. DeBorde; Buick, Frank Hahne; Ford, M. Ed. Wilson; Schacht, B. B. Tippins; Buick, T. E. Youmans; Buick, D. P. Everett; E-M-F, Charles Graham; Buick, A. Weill; Maxwell, E. G. Gager.

The technical committee soon set to work examining the cars, but discovered that it was impossible to get through that night, so gave up the work until the following day. It was found that two or three cars in each class had made perfect scores, or very

From Stereograph, Copyright, By Underwood & Underwood, New York

Capturing the Juicy 'Possum in Sunny Georgia

nearly perfect, and to decide the winners it would take almost a week. The winners will be announced by the middle of next week. Those that have a look-in at first prizes in each class are:

Car	H.P.	Owner	Driver	Observer
CLASS A				
Stevens-Duryea	24	C. Barrow	C. Barrow	J. Jones
Buick	40	R. V. Connerat	J. S. Toole	H. F. Kuck
Packard	30	N. G. Browne	N. G. Browne	C. Osborne
CLASS B				
Maxwell	30	W. H. Towles	W. H. Towles	W. J. Robider
Maxwell	30	W. L. Hazzard	R. Brockett	G. R. Foltz
Crawford	30	Savannah Taxi Co.	W. C. Mahoney	W. T. Knight
CLASS C				
Maxwell	10	Maxwell-Briscoe Co.	E. G. Gager	H. Wright
Buick	22	A. L. Well	A. L. Well	A. Ferst

J. L. Sibley, Jr., driving a Cadillac, started the same morning the Savannah club left, and, suffering from record-breaking fever, dropped out of the run, making the 304 miles in twelve hours.

LIMITATIONS OF STRANG'S ATLANTA RACER

ATLANTA, GA., Nov. 13—Strang's big Fiat racer, it appears, is helpless when attacked by the puncture demon. Strang had the 50-mile free-for-all at his mercy, when, on the eighteenth mile, he had a blow-out on his right rear wheel, which caused him to drop out. It is said to be impossible, for some mysterious reason connected with the construction of the big car, to make a quick tire change on it. Strang had done the first ten miles in 7:18.32, at the rate of 82.1 miles an hour.

Experts who have looked up the comparative "dope" on the Fiat and Barney Oldfield's Benz find that the Italian has much the greater cylinder capacity. Its bore is 7.48 inches and its stroke 6.29 inches, giving it a piston displacement of 1,106 cubic inches. What this means will be realized when it is remembered that the biggest stock car class is for 451 to 600 cubic inches displacement. The bore and stroke of the Benz are 6.1 and 8 inches respectively, giving it a displacement of 935.5 cubic inches.

THE STUNT OF ONE SALES MANAGER

ATLANTA, GA., Nov. 12—What is regarded as one of the most remarkable feats ever accomplished by an automobile was the run up Stone Mountain yesterday afternoon by a 12-horsepower Maxwell runabout. The trip was the result of an ambition on the part of General Sales Manager C. W. Kelsey, of the Maxwell-Briscoe Company. About a year ago some mention of the mountain was made in Mr. Kelsey's presence and he then ventured the opinion that if man could climb the steep ascent his machine could, too. He was laughed at, but quietly waited his time.

Thursday afternoon he announced himself ready to make the trial and chose E. G. Gager, of the Pittsburg office, to accompany him. Another party went in one of the larger Maxwell cars and included M. Rambo, of Birmingham; William Towers, of Rome, and Robert Davis, of Detroit. Mr. Kelsey chose the same machine that made the tour from New York to Atlanta, and which immediately on its arrival here was shipped to Savannah and made the Savannah-Atlanta *Constitution* good roads run with a perfect score.

The start from Atlanta was made about 1 o'clock and the run out to Stone Mountain accomplished in about forty minutes. The little machine was sent immediately at the beginning of the ascent and went up like a squirrel climbing a tree.

When it reached the top the party were so excited they could hardly express their admiration, and in order to confound all scoffers, Mr. Kelsey left the machine standing to remain there over night. So, if you don't believe this, go up and look at the little marvel yourself.

CHICAGO AUTO DRIVERS ORGANIZE

CHICAGO, Nov. 13—To combat the percentage of reckless chauffeurs and other automobile drivers who are bringing discredit on all, 115 owners and chauffeurs organized at a meeting yesterday evening the Auto Drivers' Protective Association. Walter W. Wilcox was elected president, and Neil Gronberg secretary. The principle of the organization is the rigid enforcement of the laws.

May Race in Golden Gate Park

On the Main Drive of Golden Gate Park—Dutch Windmill to Right

A Stretch on the Parkway Shows a 70-Miles-per-Hour Possibility

Sloat Boulevard, Recently Completed, Without a Bump in It

SAN FRANCISCO, Nov. 13—With the Oakland Portola road race a brilliant success, the officials of the Automobile Club of California have already begun to plan its renewal every year so that it may become as much a fixture as any of the big contests of the East. It is felt, however, that the race ought to be held in this city, as the festival with which it is connected is distinctly limited to San Francisco. When the plan was broached for holding the race here the instant objection was made that no suitable course for such a race could be found within the city limits. But one of the most enthusiastic racing men of the club had been doing some quiet investigating and it did not take him many minutes to show the committee that San Francisco has within her borders the finest race course in this country.

The course as proposed by the racing man goes through the famous Golden Gate Park, down the Great highway, over Sloat boulevard, and back into the park by the way of Nineteenth avenue. "Jack" Fleming. who drove the winning Pope-Hartford in the Portola race, declared that with one exception every turn on the course can be taken at sixty miles an hour, and the noted driver spoke with authority, for while the park police were not looking he tried out the turns with his racer.

The course starts and finishes where the main driveway joins the south drive in the park. It swings into the Great highway where the Norwegian ship *Gjoa*, the first vessel to sail through the Northwest passage, lies at rest, and from there by an easy double turn into the new Sloat boulevard, which is wide enough for ten machines to run side by side on it. The turn from the Sloat boulevard into Nineteenth avenue is sharp, but it could be banked so that racers could pass it without danger. From Nineteenth avenue the course plunges up a short incline into the park again. The total mileage of the course is slightly over 11 miles, the ideal distance for the road race.

Within the park the roadway has the finest oil surface ever constructed in this State of oiled roads. The Great highway is also oiled, and the hard sea sand forming the foundation makes it an ideal road. The Sloat boulevard, but lately constructed, is an example of what an automobile road ought to be.

Just before approaching the Ocean boulevard the Pacific can be seen in the distance, and on the right is the famous Dutch windmill recently presented to San Francisco. The photograph at the top of the column illustrates this view.

Maurice Clement, in New Bayard-Clement Auroplane, Which He is Now Flying at Issy les Moulineaux

WHAT THE FRENCH MAKERS ARE NOW PRODUCING

PARIS, Nov. 12—Although there is no automobile salon in Paris this Winter, French constructors have not altogether neglected to produce new models or to modify their old ones. Modifications, indeed, will be much more numerous than the creation of new types. It can be taken, as a general rule, that all the old types remain with but few modifications with a view to simplicity and silence. The new creations are small cars, or rather light cars, varying from 12 to 18 horsepower, designed for town service with closed bodies, or for touring work with open bodies. This class of automobile is the only one meeting with any real success in Europe at the present time. The moderate-powered car has its limitations, but its advantages are such that it not only interests present owners, but by reason of its moderate price and economical up-keep attracts those who have not hitherto been interested in automobiling.

What Darracq Has Produced

Darracq has produced a car of this type, which is really a simplification and development of the previous models, the features being a design of such a nature as to reduce the cost of labor and thus make possible a very cheap production. The frame is original, being pressed in its entirety from one piece of steel and having its side arms and undershield all in one piece. The side members are of inverted U-section, and the lips on which the engine and gear-box are mounted prevent distortion, and absolute rigidity is secured by a cross-member at the front of the pan and two other members behind it, one being at the bend of the frame and the other at the extreme rear. All riveting is economized with the exception of the three cross-members mentioned and the dumb irons.

Maurice Clement at Wheel of Bayard-Clement Biplane

This type of frame is the outcome of a long series of experiments, one of which was the production of a complete frame and a two-seated body in two steel stampings. The new Darracq engine is a four-cylinder monobloc of 85 to 100 millimeters bore and stroke, rated at 14-16 horsepower. Only slight changes have been made in the design of the engine, one of them being the fitting of an oil float, the spindle of which projects through the crankcase breather and indicates the amount of lubricant in the base of the crank chamber. The gearbox, bolted to the inswept portion of the frame, is of very short over-all length, and provides three speeds forward and reverse. Shaft drive is employed with a universal at each end. There is no torsion rod, the three-quarter elliptic springs acting as distance pieces and resisting the reaction of the driving effort. Engine control is by accelerator pedal; the dashboard is perfectly free, not even carrying a sight feed, while the gear change is of the selective type, the levers being steel stampings.

Renault Has Four-Cylinder in One Casting

Renault has in hand a four-cylinder model in one casting, this being the first time that cylinders have been produced at this establishment in other than twin castings. Details of the motor have not yet been decided upon, but it is doubtful if any very important changes will be made other than in the method of casting. A new six-cylinder model of only 18 horsepower is being produced, and attention has been paid to the American market by the creation of a 20-horsepower Colonial model, with enough clearance for any American road, and all parts strengthened for high-speed work over rough surfaces.

Panhard Joins the Monobloc Division

Panhard, after being an advocate for years of separate casting, has brought forth a monobloc engine of 12-14 horsepower. The four cylinders have each a bore and stroke of 3 1-10 by 4 7-10 inches, valves on one side, a crankshaft carried on three bearings, thermo-syphon circulation and high-tension magneto. Piping has been reduced to a minimum by casting the intake and the exhaust manifolds with the cylinders, thus giving the exhaust the advantage of the cooling water and warming up the intake. The high-tension magneto, with fixed sparking point, is alone on the valve side; the leads are very short, for the sparking plugs are carried in the cylinder head immediately over the intake ports.

The carbureter, a modified Krebs, is alone on the opposite side of the engine, the only intake piping being a single length passing into the manifold cast with the cylinders within the water jacket. Thermo-syphon cooling, also an innovation for Panhard, is through a special type of gilled tube radiator, with a water tank assuring a head of water and very wide area of straight pipes. Lubrication is a combination of drip and forced feed, the flow being to the engine bearings and to the gearbox. The power is transmitted through a cone cutch, a three-speed gearbox and propeller shaft to a rear live axle. An armored-wood torsion rod on the girder principle is used, though the forward halves of the three-quarter elliptic springs are used as radius rods. This is the only "armoring" about the car, the frame being of the usual pressed-steel type.

Henry Fournier Now Operating Voisin Biplane

Clement Copies Renault Radiator

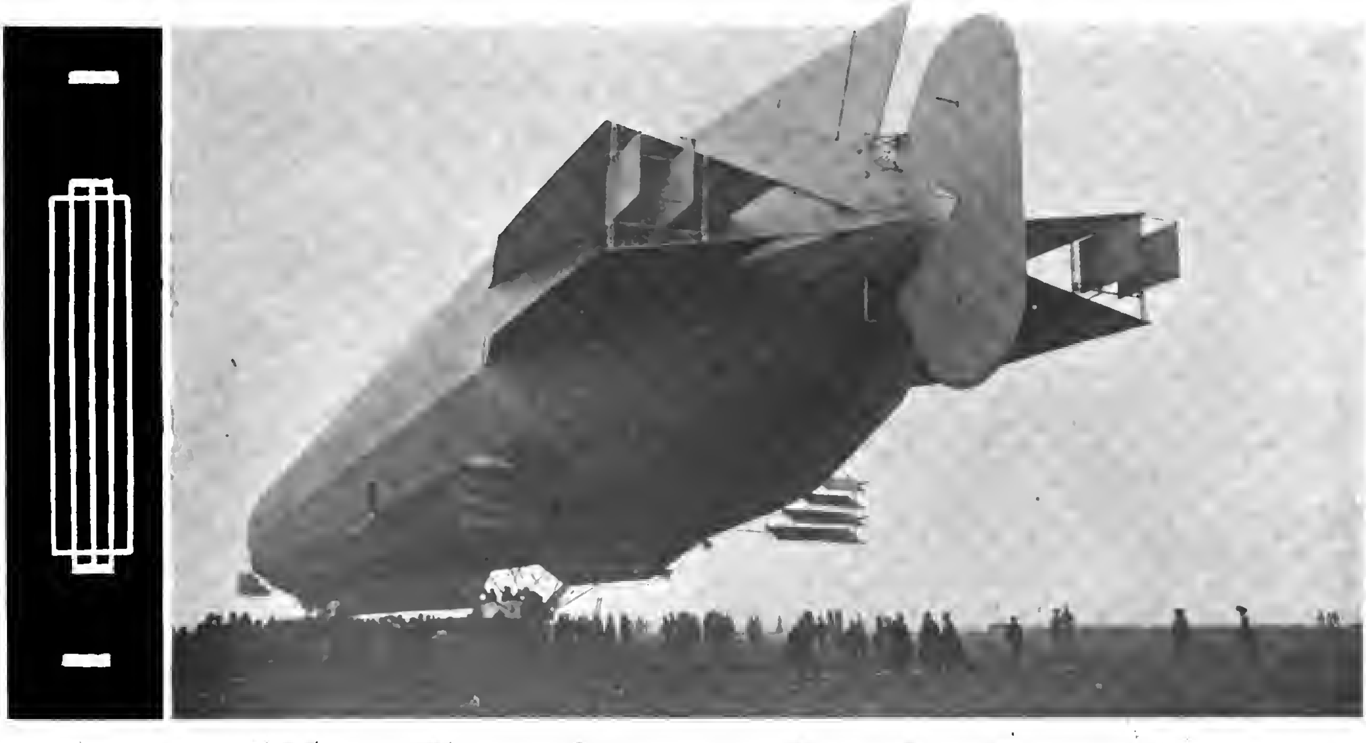
Bayard-Clément is another large firm having copied the Renault design of a radiator on the dashboard with thermo-syphon water circulation. The models on which this has been produced are two and four-cylinders identical with the exception of the number of cylinders. In each case dimensions are 3 1-10 by 3 7-10 inches bore and stroke, the fours as well as the twos being a single casting. Every effort has been made to produce a simple, clean-cut engine. The intake manifold is cast with the cylinders; the water piping and exhaust manifold are separate, but each one is held by a couple of bolts only. Valves are on one side, and magneto in front, in the most accessible position when the radiator is at the back.

The carbureter is a model of simplicity, consisting of a float chamber having its top held on by a spring finger, and a vertical nozzle, around which is a straight tube with a bell bottom, the upper end of which screws into the intake manifold. There are no oil pipes on the engine whatever. The lower portion of the crankcase forms an oil tank, from which the lubricant is pumped into a series of troughs for each connecting rod to dip into; the overflow finds its way back to the base of the chamber. On the right-hand side of the engine is a combined oil filler and crankcase breather, through the cap of which projects the spindle of a float in the oil chamber, this indicating the amount of oil in the base. There is a three-way cock by the side of the filler, which allows more oil to be run into the case or excess drawn off as desired. Paris regulations against smoky exhausts are doubtless responsible for these details.

A three-speed progressive type of gearbox is employed, one of the features of which is a lever passing directly onto the gear-shifting mechanism without the use of any intermediary. This is rendered possible by having the driver's seat on the left instead of the right-hand side. Final drive is by propeller shaft carrying a single universal joint.

New Type of Concentric Valve

In connection with a four-cylinder aeronautical motor, Panhard has produced an interesting type of concentric valve. The motor has four separate steel cylinders with copper jackets having a bore and stroke of 4 3-10 inches by 5 1-2 inches. The cylinders are set so close together that the circulating water ports touch and are made watertight merely by a steel collar lined with rubber. The valve seating is screwed into the cylinder head. It comprises a guide for the concentric valve, the intake port, and two arms to receive the rocker-arm bearing. The stem of the exhaust valve is a hollow steel cylinder with the walls cut away to allow admission into the tube. Within the



This Excellent Photograph of the Zeppelin Airship Gives a Comprehensive Idea of its Hugeness exhaust valve is the intake valve, the seating of which is on the head of the exhaust. Although the concentric valve is not new, being adopted by several French makers of aero engines, most of them make their intake automatic.

On the Panhard the intake, like the exhaust, is mechanically operated. By means of the vertical push rod and the overhead rocker arm, the exhaust is operated in the usual way, and although the intake is carried down at the same time, it remains seated on the head of the exhaust. When the inner end of the rocker arm is raised, causing the exhaust valve to be brought back to its seat, it has in turn to depress the intake. The end of the rocker arm is forked, and as it rises this end lifts up a second and shorter rocker arm, pivoted on the disc-shaped end of the exhaust and at right angles to the main rocker. A suitable spring causes the roller at the end of the push rod to follow the depression on the face of the cam, without which the rocker arm would not rise sufficiently to allow the forked end to fully operate on the intake valve rocker.

The intake manifold runs down the head of the engine, the mixing chamber, with air inlet, being in its center and the carbureter by its side. The combustion chamber is hemispheric, with sparking plugs inserted just below the concentric valves. As the fresh cool gases pass within the cylindrical exhaust valve stem, this latter is always maintained at a reasonable temperature. The motor is rated at 35-45 horsepower. Fully equipped, but without cooling water, its weight is 200 pounds.

TENTH GARDEN SHOW WILL BE ELABORATELY DECORATED

SOME interesting light on the methods of decorating Madison Square Garden for the Tenth National Automobile show, which will be held there during the week of January 8 to 15, has been given by W. W. Knowles, the decorator, and the committee in charge of the show, consisting of Col. George Pope, chairman, Charles Clifton, E. P. Chalfant and Secretary Merle L. Downs. The discussion turned upon the details of the preparatory work which is now in progress. From the way the various items were dealt with it seemed almost as if the committee were planning to create a permanent hall of art instead of a seven-day affair in an exhibition building. It is almost unbelievable that so much elaboration ever would be entered upon for a single exhibition. Already carpenters, sign-makers, wood-workers and painters are working zealously on the skeleton for the decorative creations.

In seeking to produce a proper setting for the automobiles, motorcycles and accessories, the show managers will not spare expense; this is made very clear by the fact that more than $30,000 is to be expended for the decorations. The annual automobile show in the Garden is becoming every year more important as a social event, at which the latest fashions in both cars and costumes are displayed, and for several years now it has been the yearly affair for which the Garden is most handsomely decorated. White and gold are the colors that have been selected to predominate in the decorative scheme next January, although crimson and green also will be strongly in evidence. On the whole, the Tenth National show, under the auspices of the Association of Licensed Automobile Manufacturers, at which are shown only American cars, the output of representative makers will be brighter in its general tone than any of its predecessors, which is saying a good deal, past exhibitions considered.

At the show of last January the employment of plaster statues and other staff work was done away with to a great extent. The forthcoming show will be practically free from this rather tawdry class of ornamentation and an effect of solidity and massiveness will be produced, together with an impression of distance, breadth, and general roominess. At some former shows the visitor entering the Garden was confronted by a mammoth piece of statuary which interrupted the view of the *ensemble* on the floor beyond. This time a Roman seat, or fountain, which is not of a height to assert itself offensively, and permits a comprehensive view of the Garden, will be constructed opposite the entranceway to aid in the plan of "opening up" the interior.

The fountain will be in the form of a low abutment of gray stone, curving gracefully about the spaces of those exhibitors that face the entrance on the Madison avenue side. It will have a trough-like basin, and at each end and in the center water will spray from the mouths of griffins and gargoyles upon the pool beneath, made iridescent by cunningly hidden lights. The falling water also will be electrically radiant. There will be goldfish and natural pond-lilies in the pool and mingling with the natural lilies will be artificial water plants from which will radiate other vari-colored lights. Carved into the front wall of the fountain will be a long settee for the visitors. Two bay trees will be seemingly growing through this seat.

ITS TRIMMINGS ARE GOLD PLATED

SOUTH BEND, IND., Nov. 15—One of the most elegant and elaborate automobiles ever turned out of the factory, a Studebaker landaulet, was recently shipped from this city to San Francisco, where it was on display in the salesrooms of the Studebaker Brothers company during Portola week. An idea of the elegance of the machine may be gained when it is stated that all the metal trimmings of the car are gold plated. The two headlights, the sidelamps and the taillamp, grease cups, hub caps, body handles, both inside and out, are gold plated. The horn and tube, the mouldings on the running boards, the gear shift lever, the emergency brake lever, the glass front and hood hinges, handles and catches are all gold plated.

The interior of the car is no less elegant than the outside; it is upholstered in a covert shade of the finest broadcloth with handsome gold lacing. The electric light globes are of cut glass and when the switch is turned the interior is flooded with light. The motor is of 40-horsepower and is of the new Studebaker type, the "G-7." All the new features of this model are embodied in this car, which is painted blue with a fine white stripe.

The immense Studebaker plant promises to enjoy one of the busiest years in its history during the coming season. A volume of orders is awaiting shipment, with more coming in daily.

TO PROTECT BRIDGES OF CHICAGO RIVER

CHICAGO, Nov. 15—A suggestion to the board of managers of the Chicago Automobile Club, which is to take up the matter of safeguarding the bridges at a meeting to be held today, is made in a letter sent to that organization by the Walden W. Shaw Taxicab Company, which offers to contribute $100 to a fund to be used for the erection and maintenance of permanent iron gates at the bridges in case the city declines to do so. The Shaw Company feels that such gates are necessary for the protection of the traveling public, and believes they should be placed 40 or 50 feet from the brink of the river. Mr. Hertz, of the taxicab company, points out that accidents occur even when a car is keeping well inside the speed limits, it being possible to skid on a wet pavement even with a speed of ten miles an hour.

AUTO TRADE INCREASES CHICAGO VALUES

CHICAGO, Nov. 15—Michigan avenue frontages in the vicinity of automobile row are rapidly advancing in value. Leon Mandel, of Mandel Brothers, of department store fame, has just purchased 150-foot frontage in the block south of Twenty-eighth street, for which he paid $250 per front foot. It is the only plot available in that section, and several auto concerns are after it.

Should Gears Progress Geometrically or Arithmetically?*

By Louis Lacoin

AN explanation can hardly be clear unless every one of the words used in it is clearly defined—unless its entire signification is made plain. It is necessary for the benefit of the non-technical reader, not to go beyond the usual terms. Unfortunately, however, that is not always possible. How, for example, can the difference which exists between the two series of speed changes of an automobile be explained, when they are merely expressed by the following numbers: 12-21.5-31-40.5, or 12-18-27-40.5? In the first case, the steps are regularly spaced; in the second, each is 1.5 times that of its predecessor.

Certain builders prefer the first series. Others have a leaning toward the second; they find that the motor "picks up" better, when there is a constant relation between the different steps in the speed. To be precise, they say that the series of speeds of an automobile should be in *geometric progression,* rather than arithmetical progression. These expressions can convey no very definite meaning unless just what these progressions are is known, and just what constitutes the difference between a geometrical and an arithmetical progression. For the benefit of those readers who are not familiar with the terms, they are explained here, in addition to which the manner in which they came to receive their names is also appended.

In mathematics, there is an infinity of progressions; they comprise all those series of numbers which follow a determined law. Each number, or *term* of the progression, is deduced from its predecessor by means of a calculation which is always the same. The most simple calculations being the four operations of arithmetic, the most simple progressions, as well as the most common, are those which are formed by successive additions of the same number, or by substraction, multiplication, or division. Progressions formed in this manner have received the designation of arithmetic, ascending or descending, and of geometrical progressions, increasing or decreasing. The geometrical progressions may be formed, just as in the case of the others, by purely arithmetical operations, but they may also be formed geometrically, as will be shown presently. From the latter comes their name, and it is well to distinguish the two by different appellations, as their properties are different.

Arithmetical Progression—The law governing the formation of the arithmetical progression is very easily comprehended. Each term is deduced from its predecessor by the addition, or subtraction, as the case may be, of a quantity that is always invariable. For instance:

2-4-6-8-10-12

or 1-3-5-7-9-11-13-15

are two series of numbers in arithmetical progression. Both are termed ascending progressions, because each succeeding term is greater than its intermediate predecessor. In both cases their formation consists of the simple addition of the same number, *i.e.,* 2. This constant is termed the ratio of the progression. Descending arithmetical progressions are formed by the subtraction of a constant, as for instance:

10-9-8-7-6-5-4-3-2-

a descending arithmetical progression, of which the ratio is 1.

To distinguish them further, the first two would be designated as arithmetical progressions, of which the ratio is plus 2, and the third, as minus 1, making it unnecessary to state whether an arithmetic progression is ascending or descending, as the signs plus or minus indicate this. When they are omitted, it is assumed that the progression is ascending. In this manner, the speeds of an automobile are represented, in kilometres per hour, by the following: 12-21.5-31-40.5, this being an arithmetical progression of the ratio of 9.5.

Geometrical Progression—Multiplication and division are the operations involved in the formation of the geometrical progression. To produce each succeeding term, its predecessor is either multiplied or divided by a fixed quantity. This constant, as in the case of the arithmetical progression, is also called its ratio. The series of numbers:

1-2-4-8-16-32-64

is a geometrical progression of which the ratio is 2, while

18-8-4-2

is another of the descending order, but having the same ratio.

It will be observed that the law of the formation of the last progression may be expressed in two ways. It may either be said that each is equal to its predecessor divided by 2, or, what amounts to the same thing, that it is equal to its predecessor, multiplied by 0.5. In order to avoid confusion, the latter operation is always indicated, and 0.5 is known as the ratio of the progression. A geometric progression is increasing when its ratio is greater than 1, and decreasing when less than unity. We have already had an example of two arithmetical progressions that were totally different, yet each had the same ratio. This is equally the case with the geometrical progression. Here are three having 2 as ratio:

3-6-12-24-48-96-192
5.5-11-22-44-88
1.1-2.2-4.4-8.8-17.6

Their Application to the Auto—Let us see how the geometrical progression may be applied to the change speed gears of an automobile. Assume, in order to have terms of comparison, that the extremes of the speed are 12 and 40.5—the figures we have already employed. It is always possible to find a ratio which will make the problem possible. Here this ratio is the quantity 1.5. The result of three successive multiplications by 1.5 gives the following series of speeds:

12-18-27-40.5

while the arithmetical progression would be:

12-21.5-31-40.5

The difference in the formation of these two progressions will be clear at a glance. In one, there is an equal distance between speeds, *i.e.,* 9.5, while in the other, there is an equal relation between the speeds as $\frac{18}{12} = \frac{27}{18} = \frac{40.5}{27} = 1.5$, the relation each term bears to its predecessor.

Even though the arithmetical progression appears to space the speeds better, the motor accommodates itself infinitely better to the geometric progression, for the following reasons:

Let us take a motor the most favorable speed of which lies between 1,000 and 1,500 r.p.m. If the speed may be maintained within these limits it will be working under the best possible conditions. But with each change of speed, the number of turns of the motor vary in inverse proportion, and if two of the speeds, the first and second, for example, bear the relation of 1.5 to each other, the motor running accelerated on the first speed will be

* Translation from "Omnia" by C. B. Hayward.

turning over at 1,500 r.p.m. Passing to second, which means dividing 1,500 by 1.5, its new speed will be 1,000 r.p.m., which means that it will still be within the limits of its most favorable operating conditions, upon reengaging the clutch for second speed. If the successive speeds be all in the same relation, the motor, except on the first slow speed, or the fourth accelerated speed, will not have to make a number of turns less than 1,000 r.p.m. or greater than 1,500 r.p.m. Should it race or slow down overmuch, a change of speed will bring it back within the desired limits.

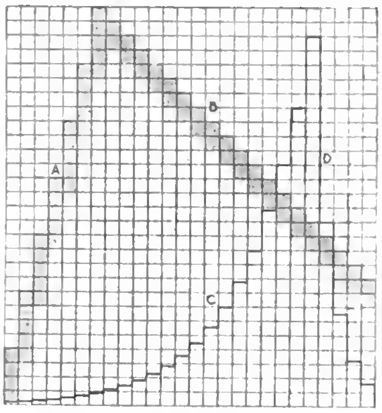


Fig. 1—Showing different progressions

Under such conditions the motor will always produce its maximum effort, and to achieve this the geometric progression is certainly ideal.

Arithmetic Progressions Compared — To show how true the foregoing is, a contrast may be drawn between it and the variations of running condition brought about by the use of an arithmetical progression between the same limits, as:

12-21.5-31-40.5

The two first speeds give as their relation 1.79, and at the moment of passing from first to second, it will either be necessary to race the motor until its speed reaches 1,790 r.p.m., to redescend to 1,000, or, in case the motor has not reached higher than 1,500, its speed will fall to 837 r.p.m. In both cases, it will be outside of the limits of its most favorable operating conditions.

On the contrary, in the two following changes $\frac{31}{21.5} = 144$, and $\frac{40.5}{31} = 1.305$, the variations in the r.p.m. rate are very small. Why not profit to the full extent of the flexibility of the motor at these two higher speeds, when at the lower two it is so abused. This involves an anomaly that is excusable to but a certain degree.

Instead of dwelling on the point, let us explain the difference in another way by referring to the first illustration, showing the arithmetical progressions A and B, and the geometric progressions, C and D. It will be seen that in the aritmetical progressions the steps fall either above or below one or the other of the equal quantities. In A, for example, each number is raised four units more than its predecessor; in B, it is one unit less, but the ascent and descent are always regular.

In the geometric progression, on the other hand, the increase takes place in proportion to the increase in the number. Each number of the series C is greater than its predecessor by a quantity equal to one-fourth of the number. Finally, in D, which is a decreasing geometrical progression, each number is half of the preceding one. Mathematicians base numerous calculations on these progressions, but they are without immediate interest in the present case. Ability to distinguish between the two is the important thing, and this is not difficult, as will be seen.

Fig. 1 has served to show in a striking manner the difference between the two progressoins, and it has the further advantage of showing the *raison d'etre* of their appellations. Mention has already been made of the fact that in the arithmetical progressions shown on the diagram in question, the steps rise one above the other by equal quantities. But it must be added that the extent of the quantity is not known except by that characteristic. Without having the step of the diagram, neither the numbers which form the different terms of the progression, nor the ratio of the progression would be known. The curve A might represent quite as well an arithmetic progression of the ratio 1, if we take as unity the measure of the height of the steps, that is, the vertical distance separating two consecutive steps, as of the ratios of 2, 3, or 4, or we might take for unity, one-half, one-third, or one-quarter. It is well known that in certain diagrams the measure of the length of the step may exceed that of its height, and in consequence, the length of the steps gives no indication of the exact value of their height, expressed in figures. As a result, diagrams, or to put it in another way, geometry, is of no assistance in the arithmetical progression. All arithmetical progression may be represented geometrically in the same manner, simply going up the given distance each step.

Taking up the geometrical progressions, C and D, it will be seen that by simply comparing the heights of the two series of steps, the fact that the first of these two progressions has a ratio of 1.25 and the second a ratio of 0.5 will be known. This geometric characteristic distinguishes this type of progression from the other, but does not suffice to justify its name. The true origin of the latter is to be found in a method of formation which is peculiar to the geometrical progression. In fact, with the aid of geometrical constructions, it is possible to form the different terms of such a progression. There are quite a number of such constructions, but it will be sufficient to describe one of them.

Let OA be the first term of the progression, and OB the second, AO and OB being distances measured on the same line OX. Trace another line OY, also having as its starting point O and mark on it the arbitrary point C. Join CA and CB. If now a line from B be drawn to D, parallel with AC, and a second one from D, parallel with CB, it is easy to see that $\frac{OE}{OB} = \frac{OB}{OA}$. OE is, accordingly, the third term of the progression, of which OA and OB are the first two. Continuing in the same manner, the following terms, OG, OK, OM are found, from which it will be plain that the term geometric is well applied to a progression which may thus be constructed geometrically. The same figure provides a whole series of geometrical progressions, first, the one already pointed out, viz., OA-OB-OE-OG-OK-OM, and then on the line OY, the progression OA-OD-OF-OH-OL of exactly the same ratio as the preceding, but with different terms. In the same manner, AC-BD-EF-GH-KL and CB-DE-FG-HK-LM are two further progressions having the same ratio.

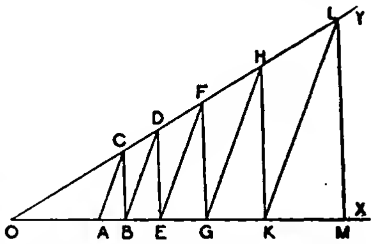

Fig. 2—Form of geometric progression

ENGLISH FORM OF PNEUMATIC SUSPENSION

The current issue of the *Automotor Journal* contains a description of an English invention designed to form a pneumatic support for the chassis of a car, entirely replacing steel springs. The apparatus, known as the Cowey pneumatic suspension, consists of four cylinders, attached to the frame, and corresponding pistons, connected to the axles by ball-jointed links. Air pressure is maintained by a motor-driven pump, with a reservoir, supplying all four cylinders. The air inlet valve to each cylinder is controlled by the piston, through a coil spring and oil-filled dash-pot. The ordinary shocks of the road do not affect the valve, but a steady load, such as that of an extra passenger in the tonneau, will open the valve and let in more air, raising the frame to normal position. The pistons are lubricated and sealed by a layer of oil on their heads, maintained by oil carried by the incoming air. The suspension has proved very easy-riding. Its relative increment of stiffness caused by a given travel of the axle toward the body is very much less than that of a steel spring. At the same time it automatically acts as a shock absorber, checking the recoil of its own motion.

Advantages of Multiple Ignition Batteries*

By A. L. Haskell

ONE of the main objects of the manufacturers of gasoline engines of all kinds at the present time is to furnish to the user an outfit that is practically "fool proof" and free from trouble. It is the purpose of this paper to show what dry-battery manufacturers have been doing to help attain this object.

No part of the equipment of a gasoline engine is so subject to the control of the operator as the ignition devices, and since the operator is more often a mechanic than an electrical man, it is very desirable to have the whole ignition outfit in such shape that his adjustments will not do an appreciable amount of damage. On account of its simplicity, efficiency, accessibility and low cost, the dry battery is particularly valuable in this connection. The other desirable quality is reliability, and it is to insure this point that the dry-cell manufacturers have devoted much time, labor and money in research work.

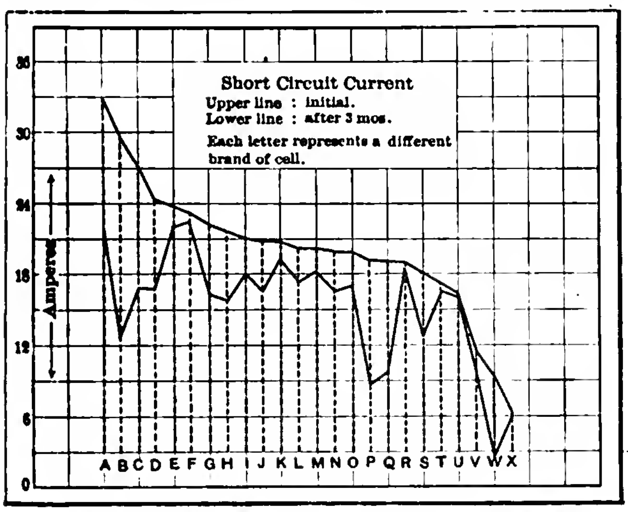

Fig. 1—Curve of short-circuit current in amperes

How the Perfect Battery Is Evolved—The batteries are tested a number of times in the course of manufacture; are then seasoned for a sufficient length of time to allow any internal defect to show itself; then subjected to a final inspection and test before shipment. This factory inspection is very necessary to insure the customers getting a uniform and satisfactory product, for, as we will now show, it is practically impossible for the user to determine beforehand whether the battery he is buying is a good one or a poor one.

The method quite often followed is to test out batteries with an ammeter and go on the assumption that a battery that registers a high current is a good one, and one registering lower in amperage is not so good. Unfortunately, this method is practically valueless, as will be shown by the illustrations.

On the drawing Fig. 1, showing the short-circuit current of a number of batteries of different makes, the letters A, B, C, D, etc., each represent a particular brand of battery, and the upper line shows the corresponding initial amperage of each battery. For instance, battery A has an initial amperage of 33; B runs 29; K runs 21, and X runs only about 6 amperes. The lower irregular line indicates the amperage of each cell at the end of three months standing idle on a shelf. It will be seen that battery A dropped from 33 to 20; battery B has dropped from 29 amperes to 13; battery F has dropped from 23 to 22 1-2 only, and so on. Since it is not always possible to put dry cells into service immediately after manufacture, and they are sometimes kept on the shelves for several months before reaching the user, it is evident that the amperage reading alone is of very little value unless the characteristic initial current and the age of the battery are known.

No Real Relation Between Initial Amperage and Service Capacity—In Fig. 2 the letters represent the same batteries batteries, the solid black line represents the initial current of each, and the irregular dotted lines represents the service in ampere hours given by these batteries under accurate testing conditions. The ampere-hour figures are given on the right-hand side and the initial current figures are given on the left-hand side. Battery B, which registered 30 amperes to start with, gives 25 ampere hours; battery L, which registered 20 amperes to start with, gives 36 ampere hours, and battery T, which registered 17 amperes to start with, gives 43 ampere hours. The diagram shows very clearly the lack of any real relation between the initial amperage and the service capacity.

This amperage test does have some value, however, in the fact that if it is known how high a certain battery generally tests when new, the current reading will show whether the battery is very old or has been used to any considerable extent. If a dry cell is supposed to register 20 amperes normally, and is found when tested to show from 18 to 22 amperes, it is a good sign that the cell is in good condition. If, however, a battery normally shows 30 amperes or higher, as some of them go, and is found testing 18 to 20 amperes, it either means that the battery is deteriorating very rapidly or is quite old.

It is easy to explain why a high amperage does not necessarily mean a good battery, as this amperage is only an indication of the internal resistance of the battery, and has nothing to do with the service life of same. If a cell were made up with the mix composed entirely of active chemicals with a high resistance, the internal resistance of the whole battery would be high and the resulting initial amperage would be very low, although the service life obtained might be good. If, on the other hand, there were very little of this high resistance active chemical in the mix, and some substances with a low electrical resistance, but which had no beneficial action in the battery, were introduced, the current would be very high and the service life proportionately short. The only advantage of such a cell would be that it would sell easier to a novice than one registering a lower amperage. The best practicable method, of course, for

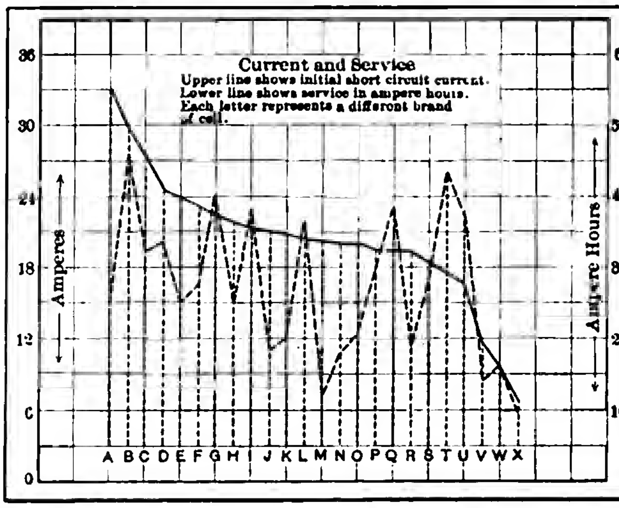

Fig. 2—Short-circuit current and service in hours

* Paper read before National Gas and Gasoline Engine Trades Association annual meeting at South Bend, Ind., summer of 1909.

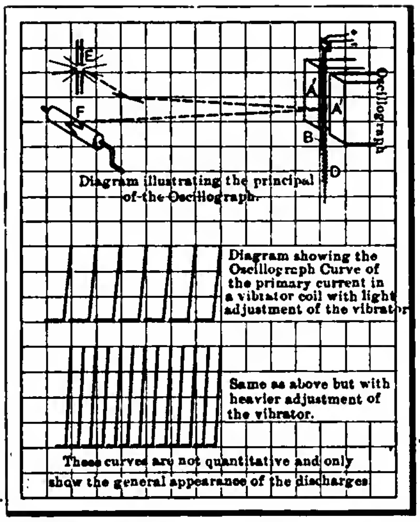

Fig. 3—Construction of the oscillograph and several typical curves made by it

a manufacturer to follow in the long run is to make up a battery to give the maximum amount of service under the conditions in which the battery is intended to be used, and let the resulting amperage be what it may.

Some Coils Draw More Current Than Others—There are certain ignition devices on the market at the present time that give most satisfactory results in operation on a very small amount of current; some of them, using a mechanical make-and-break with a non-vibrating coil, will operate a four-cylinder engine on an average current consumption of from .1 to .2 of an ampere and develop the maximum amount of power from the engine. There are coils of the vibrator type that will do the same thing on an average drain of .2 to .3 of an ampere. With a coil of either of these types the user is practically assured of getting perfect service from dry cells.

Unfortunately there are a number of other coils that require an excessive amount of current to operate satisfactorily, and it is usually the case also that these coils require frequent adjustment, as a consequence of which they are drawing much more current than they need by the time the adjustment has been changed a few times. In the first place, the coils are poorly designed, the vibrator is not made of the best material, the contact points are not made of material that will stand the pitting due to the heavy current, and the operation in general is apt to be unsatisfactory. There has been a marked improvement along this line, however, in the last year, and excellent oils can be obtained at a very reasonable price.

A number of manufacturers have made the claim that a high current consumption with a coil is necessary to give a fat, hot spark that will develop the maximum amount of power from an engine. The importance of the big spark has unquestionably been overrated, as tests that we have made on engines equipped with a brake and on a number of automobiles have proved that a spark can be obtained with a reasonable drain on the batteries that will operate the engine with just as much power as will the excessive spark, and has the further advantage of not causing pitting and burning of the contact points.

Where a mechanical contact maker is used, so the explosion takes places at exactly the same point in each cylinder in a multi-cylinder engine, the degree of intensity of the spark does not make an appreciable difference, provided you have a good spark to start with. In other words, there is a certain point beyond which it does not pay to go, and this point can be reached with a very economical use of current.

What Test Results Show—It might be of interest to show here some preliminary results obtained with standard types of coils in testing with an oscillograph. This is an instrument with which very delicate oscillating currents can be accurately measured, and it is claimed that this instrument will respond accurately to any number of vibrations up to 10,000 per second.

The principle of the oscillograph is illustrated in the sketch Fig. 3. A and A¹ are the poles of a powerful electro-magnet, between which is suspended a fine U-shaped wire of silver, B. This wire is held under tension by the spring D, and the very small mirror C is attached to both legs of the U at its middle point. The legs of the U are only .4 of a millimeter apart, and the diameter of the mirror C is the same. If a current flows through the silver U it will be slightly turned because of its being in the magnetic field AA¹ and its motion will be indicated by a beam of light shown as a dotted line coming from the arc E. This motion can be registered on a drum at F or can be thrown directly on a screen and observed by the eye.

The first tests made were on one unit of a coil vibrating continually. The oscillograph was connected in the primary circuit of the coil and it was allowed to vibrate with a ¼-inch spark gap in the secondary. The measurement of the maximum rise in impulse with 6, 5 and 4 cells in series, and a number of adjustments of the vibrator in each case were taken. The measurements were also taken showing the maximum of current in the secondary discharge. The appearance of the discharges obtained through the spark coil as shown by the oscillograph are indicated diagramatically on the two sketches shown below the sketch of the apparatus in the attached drawing. The upper sketch shows the appearance of the discharge when the vibrator is making a light contact and the coil is operating economically. As the vibrator is gradually tightened the record on the oscillograph glass becomes more nearly as in the lower figure.

The values of the maximum currents under various circumstances are given in the following tables:

No. of Cells	Voltage	Impulse Current	Vibrator	Primary Circuit Voltage	Primary Circuit Current	Oscillograph Record Primary	Oscillograph Record Ratio	Oscillograph Record Secondary
6	4.55	9.5	1	8.55	.70	3.36	35.4	.030
6	4.55	9.5	2	8.55	.72	3.10	32.6	.023
6	4.55	9.5	3	8.20	1.22	4.10	43.2	.034
6	4.55	9.5	4	7.95	1.70	4.04	42.6	...
5	4.0	8.15	1	7.10	.32	2.68	32.9	.015
5	4.0	8.15	2	6.90	.72	2.99	36.7	.021
5	4.0	8.15	3	6.60	1.27	2.99	36.7	.026
4	3.3	6.9	1	5.75	.21	1.94	28.1	.008
4	3.3	6.9	2	5.75	.31	2.07	30.0	.015
4	3.3	6.9	3	5.35	1.15	2.57	37.2	.021

1	3	6	7	8	9
Cells in Series	Impulse Current	Primary Current	Oscillograph Readings Primary	Oscillograph Readings Ratio	Oscillograph Readings Secondary
6	10.5	.22	2.10	20.0	.025
5	9.0	.18	1.84	20.5	...
4	7.6	.12	1.52	20.0	...

The following points may be noted from an examination of this table.

1. The actual current impulse in the primary coil (column 7) is only about one-third of the impulse measured by short-circuiting the batteries through the primary of the coil (column 3).

2. As the vibrator was tightened the average current consump-

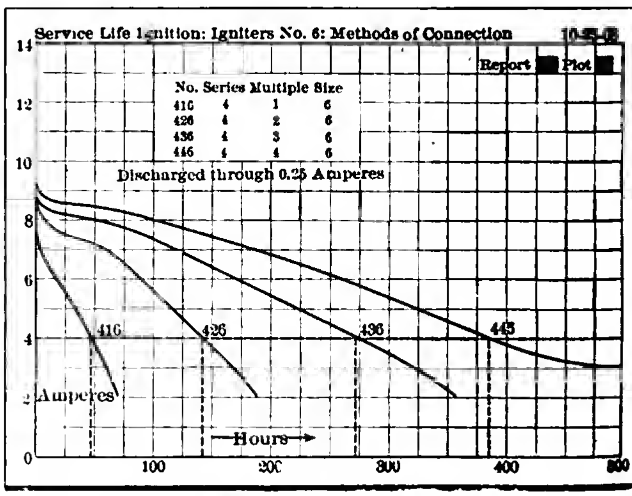

Fig. 4—Curves of varying service life with varying numbers of cells connected in multiple

tion (column 5) increased from 150% to 550%, according to the number of cells in series, while the actual impulse measured by the oscillograph increased only from 10% to 25%. This indicates that there is very little advantage to be gained by tightening the vibrator on a coil beyond a point where the current first becomes steady and even, except for the theoretical advantage that the sparks come closer together in the cylinder.

Non-Vibrating Coils Tested, as Well as Vibrating—After completing the above measurement on a vibrator a similar series was run, using the non-vibrating coil with a mechanical contact maker. The results obtained are shown in the following table, similar columns being marked in the same manner as in the previous table. Timer was revolving at about 500 revolutions when the reading was taken.

The results with this timer and coil show the following points:

1. Although the short circuit impulses (column 3) are higher than with the vibrating coil, the ratio between these impulses and the actual impulse as shown by the oscillograph (column 7) is less. This is an indication that each contact is of shorter duration than in the case of the vibrator coil.

2. The current impulse in the secondary coil is nearly as high as in the case of the vibrator coil, although the average current is very much less. This is in line with our gas engine results, which indicate that if there is current enough to ignite the mixture any excess is unnecessary, and also adds nothing to the force of the explosion.

This new field of investigation promises to give valuable results when more fully developed, but the above outline is the result of a preliminary investigation only.

By referring to Fig. 4, curves are shown indicating the discharge of batteries on ignition service when the average current with the engine running is .25 of an ampere. The vertical figures 2, 4, 6, etc., show the impulse in amperes when the batteries are short-circuited through the primary coil, and the horizontal figures marked "hours" shows the length of time they have been running when these readings were taken. The dotted line starting at 4 and running across the page indicates what is considered as the dead point of the batteries—namely, when they are no longer capable of delivering an impulse of more than 4 amperes through the coil.

The first curve shows the discharge from a single set of cells which reached the dead point at the end of 48 hours. The second curve shows the discharge of a battery composed of two sets in multiple, and these reached the dead point at the end of 140 hours. The third curve is for three sets in multiple which reached the dead point at the end of 270 hours. The fourth curve, showing four sets of cells in multiple, reached the dead point at the end of 383 hours.

Curves for Continuous Discharge—The next drawing, Fig. 5, shows a similar set of curves when the average discharge is one-half ampere continuously. Here the single set of cells runs for 20 hours; two sets in multiple for 70 hours; three sets in multiple for 114 hours, and four sets in multiple for 170 hours. The first curve represents the conditions actually obtained with an efficient ignition apparatus properly adjusted and is being duplicated every day in practice on automobile service. The second curve represents conditions met with in every-day practice when an average type of ignition apparatus with average adjustment is being used.

Another obvious advantage of the multiple connection is that batteries can be used to a much lower point when connected in multiple than when used in single series. As shown above, it is necessary for a battery to deliver an impulse of four amperes through a coil to give satisfactory service. If four sets are connected in multiple it will be necessary for each set of cells to deliver only one ampere impulse through the cell, and the battery can, therefore, be used much nearer to the point of complete exhaustion.

An interesting experiment illustrates this clearly. Forty No. 6 batteries were used in separate sets of five each until they were

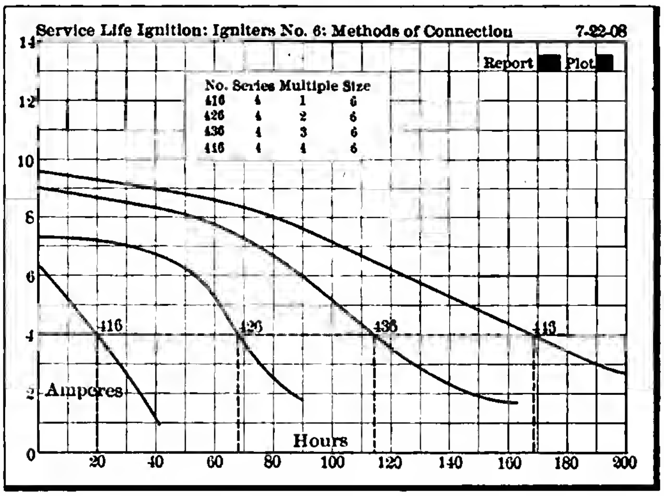

Fig. 5—Service life with a constant current output

no longer capable of running the engine. The 40 cells were then connected in single series, which, of course, gave a very high voltage, but would only run the engine for a very short space of time. We then connected the 40 cells four in series and ten sets in multiple and ran at full load for 312 hours more.

With regard to the number of cells to be used in series, it is hard to lay down a definite rule, as the voltage required depends on the type of coil used and the condition of the contact in the timer. A great many coils and timers will operate satisfactorily with four cells in series on a multiple battery and practically all of them will operate satisfactorily with five in each series when connected in multiple. By connecting three or four sets in multiple it is usually practicable to use one less in series than when used in single sets; that is, if a single set of six batteries is ordinarily used, when the multiple connection is made it would be found that five in series is sufficient.

With regard to the number of sets to be used in multiple, the object should be to provide a battery that will run from nine months to a year, and this, of course, depends on the amount of current required and the amount that the engine is run. In stationary engine practice there is a marked advantage, in the fact that the length of contact on the timer can be made just long enough to operate satisfactorily at the constant speed, and this results in a considerable saving in battery current; also changes and adjustment are apt to be less frequent, especially with make-and-break type of ignition apparatus. This means that the manufacturer or user can get a very accurate estimate of the actual amount of current required to operate the engine and can figure on the battery to give a certain amount of service.

In this class of service a multiple series battery of comparatively small size should take care of the ignition requirements from nine months to a year very satisfactorily, provided the batteries were properly protected. To insure the connections being properly made, and to provide the best protection possible, these batteries are now put up in sealed cases with all connections soldered, the cases filled with wax and only two binding posts on top of the battery to which connections are made. These cases are furnished in any size desired. This, of course, makes the battery absolutely waterproof, so that it will stand any kind of weather conditions; there is no chance of loose connections or broken ones, and unless the whole thing is short-circuited in some way, the chances of failure are practically zero. If the engine manufacturer wishes to put up batteries in this way it is perfectly practicable to do so, the main points to note being that the batteries are in proper condition when put in the box; that the connections are properly made and all tight; that the insulation between the batteries is perfect; that the wax is put in at such a temperature that a man can put his finger in it without being burned. The method of sealing, with these precautions, insures the maximum of service from the battery.

THE POSSIBILITIES OF THE LIGHT RUNABOUT

By ROLLAND C. LAURIE

BY "Light Runabout" I mean a car of ample horsepower which naturally will appeal to the man of moderate means. The present runabout of low price falls short of the ideal in horsepower, springing, and general accessibility. The method of distribution of cars need not be through intermediate agencies, but the selling can be direct from the factory to the public. A proposition like this could hardly be handled by intermediate agencies unless the sales of the car were so huge the world over in home and in foreign markets that such agencies as distributing centers could be placed. Why I would wish to emphasize this point is that the suggested design, which I put forward herewith, as to the type of runabout really required, leaves little enough profit to the manufacturer unless these cars were manufactured in very large quantities.

Making in Quantities—Now, as to this question of manufacturing in large quantities. There is not the slightest doubt that the possibilities of business on such a proposition as in an efficient $500 car are absolutely immense. From the writer's knowledge of the subject in connection with a light automobile the information of this subject that can be given to the public and trade alike is that no one at present can have any idea as to the extreme interest aroused in a proposition such as this. One concern alone received some thirty thousanl inquiries in less than one year of advertising, such advertisements not being confined to large display, and these advertisements not in any way bringing the proposition right before all the buying public, touching, as it has done, only a certain class of buyer. Another concern has had twenty thousand inquiries for one of their models of light runabout. I could cite other instances from personal knowledge of the trade; therefore the immensity of a business like this can hardly be gauged. The class of buyer to whom this car appeals is the man of moderate means, yet often a man who owns a large car already wants a smaller one for short trips. Again, we have a car which is adaptable for doctors' use, for R. F. D. carriers, and, last but not least, for our very large population of farmers who are gradually becoming interested in the automobile proposition.

As to Design—In the first place, as a general rule, present horsepower is not high enough. The engine should be at least a two or four-cylinder, 15-horsepower, water-cooled type. The water cooling could be easily of the thermo-syphon type; moreover, the simplicity and efficiency of this type of cooling is thoroughly adaptable for use in a small car. In this design of engine we could embody the long stroke, which has become so popular in England and France and has shown such success. The long-stroke engine would mean the delivery of sufficient horsepower for practically every purpose. The change speed gear could be of epicyclic or planetary type, as this design lends itself better in the light car construction than a large gear box. Another thing might be pointed out, that whatever type of change speed gear is employed, it should be strong enough to withstand hard usage. The usual type of planetary gear is frequently deficient in this respect. The final drive could be shaft or chains, just according to fancy of the designer and according to the results shown by trial on these matters.

Chain Not Defunct—It must be remembered that chain is is by no means defunct as an intermediate of power. The Panhard car designers held to the chain as long as they possibly could, for their belief in its efficiency was thorough, and, providing the chain is suitably enclosed in an oil bath gearcase, similar to the British Sunbeam, there is no reason why it should not be a perfect transmitter of power, light and yet free from complication. The shaft drive could be an alternative design, in spite of the fact of the known frictional losses in this form of transmission. The frame could be of pressed steel and the axles of suitable strength. The springs also could be improved upon, as the present day light runabout of low price is, as a rule, extremely deficient in springing. Full elliptic springs seem to give the best results, although they do not appeal to the average man as being mechanical. This is merely a matter for experiment. Probably in this design dual ignition by both battery and magneto should be included. This may sound to the uninitiated as an expensive fitting on such a car, but it can be included in such a price without the slightest doubt.

I cannot deal with the design of such a car more than by giving a rough outline, as every manufacturer has his own ideas on the subject for convenience sake. Three-inch tires should be fitted, either on wire or artillery wheels, preferably the former, of detachable pattern. In this design of car accessibility should be a leading feature, and the price should be right on the $500 mark, neither above nor below, for the car itself. There is no chimerical dream in talking of the possibilities of such a design. It can be accomplished, and the first automobile company that does really accomplish this will corner the market of the world, providing that they put a reliable machine before the public, one that will wear and in which the material is first-class throughout.

Profits Small, Returns Quick—We all know the parable of the grocery store where the profits are small but the returns are quick. In this business it is "small profits and quick returns," and the returns would be so great under the proper management that extraordinary results could be shown in less than two years' working of such a proposition. What is required is "the car for the million," yet it must be a car which can show power, efficiency, comfort, and accessibility.

Every manufacturer has his own ideas as to design of the runabout type, therefore the mere question of design, beyond leading and outstanding features which seem to be most desired, according to the general consensus of opinion from inquirers regarding the light runabout need not be touched upon. By studied standardization a clever designer can manage to produce cheaply. Every part of such a car would have to be standardized beyond doubt. Personally, in runabout design I would be more inclined to favor the sporting, semi-racing type with the seat placed far back—not *too* far, as this has a tendency to give too much vibration to the driver and passenger.

No Rumble Seat—In the first place, the sitting position is much more comfortable, and the car has a more graceful and rakish appearance; and, above this, a rumble seat cannot be fitted. Everyone knows that the runabout of to-day is abused by its owner as a general rule, as single rumble seats are fitted, frequently double rumble seats, the general impression being that as long as the engine has sufficient power to pull a load that is quite enough. Broken springs and other results of overloading do not seem to enter into the purchaser's mind at all; therefore this design of the semi-racing type has something outstanding in merit because a rumble seat cannot be fitted.

The last word which I may say on this question is that the whole matter is one of organization. First, the factory prepared to turn out a standardized car such as this would have to be of such ability that delays in deliveries would be impossible. As for the selling organization of such a factory, undoubtedly the way to place this upon the market in a practical and successful way would be for such a factory to open branches at various distributing points. There are certain cities well known to the automobile trade which form just the suitable distributing basis for such a scheme.

U. S. Automobile Imports—The monthlv summary of imports for September shows that during the month 150 automobiles, valued at $291,811, were brought into this country, as compared with 219 imported during September, 1908. For the nine months ending September the figures are: 1909, 1,208 cars, valued at $2,218,414; 1908, 956 cars, valued at $1,803,889. Of the 150 imported in September 74 came from France and 44 from Italy.

The Private Garage Problem

By Morris A. Hall

Part 5

Semi-Private Garage of Large and Exclusive Hotel, Is of Shingle and Stucco Construction

CONCRETE answers a larger proportion of the requirements for an ideal garage material than does any other. More than this, the ones which this material fills are of greater importance than those which it does not fill, or in which some other material shows a superiority. Worded otherwise, concrete not only answers the largest proportion of the essential requirements, but evaluating all of these, it has a greater total valuation than any other.

These requirements might be said to be: Low first cost, ease of erection, adaptability to architectural beauty, fire-resisting qualities, damp-resisting qualities, low cost of upkeep, great length of life, cleanliness, and low cost of foundations.

Now, cement or concrete could hardly be said to be very cheap, although, the first cost need not be high and with this medium first cost is more than offset by the fact that the life of the structure is at least twice that of wood, for instance, so the annual figure for depreciation would be but half that of the cheaper place. In addition, cement need not be painted at all, as compared with a coat of paint every other year at the longest for wood, every six months for steel, and other lengths of time for other and different materials, as brick, which should be painted about every three years, etc.

Easy Erection a Very Important Point—Probably the point which, in the case of a small garage, would carry the greatest weight in the selection of the materials would be ease of erection, for this means either less work for the man doing the work himself, or less fuss and bother by the contractor whom he hires. The latter, too, spells less expense. This point should not be borne in mind to the complete extinction of all others, for if it was, all garages would be portables. It should be given its proper value in combination with others.

Hardly anyone, even an enemy of cement, would dispute the fact that cement lends itself very well to architectural adornment, whether carried to the "beauty" point or not. Such features as ornamental corners, in imitation of cut stone, may be reproduced with practically no additional cost for materials. So, too, with details like imitation stonefaced bricks, or stones, a reproduction of field stone, in the introduction of pilasters into the walls, copings around the top edges, the construction of columns, and many other features of worth, these may be had by exercising forethought, and with little if any increase in the material cost.

As to fire and damp resisting qualities, there can be little question but that cement will hold its own. The mere fact that the floors, ceilings, and other parts are made integral with the side and end walls, the finished building being practically one structure, insures a big score for cement on the count of low cost of upkeep, particularly when taken in conjunction with the paint item as previously discussed.

Cleanliness Very Weighty in the Decision—Of all the items, none should carry greater weight than that of cleanliness. This means not alone that the place should look clean and neat when finished and ready for the car, but of greater importance, that it should clean easily afterwards, when old and easily dirtied. In this connection, it is enough to make out a case for cement, to say that the only thing needed to clean a cement garage and that, too, easily and quickly, is a hose and a source of water supply. Rubber boots will come in handy too. Of course, water can be used in the same way to clean out frame garages, stone or brick buildings with wood floors, and other kinds of motor houses, but it is by far the easiest to clean out an all-cement house, with cement floors, of course.

Cement Block Garage for One Car Is Low In Cost

Being heavy in weight, the concrete or cement place would need heavier or stronger foundation than the frame building, while the stone and brick building with cement floors stand about on a par with the all-cement house in this respect. However, even in this, the latter possesses an advantage, for the foundations are laid more readily and should

Schlesinger Private Garage, Detroit, Mich.

cost less, than in the case of the other two, to say nothing of the increased speed with which they may be laid. This latter point has not been brought up before, because the question of speed seldom if ever enters into the case. Should it ever do so, concrete scores another point. This about covers all of the important points, the discussion bringing out the finer reasons which the simple list of them would not do. As to rating them according to value, this cannot be done in a general way, since it would differ for nearly every case considered. Thus, the wealthy man would give the adaptability to architectural effect the preference over all of the others. The careful man of small means would look on fireproof qualities, combined with low cost of upkeep as of vastly greater importance to him than all of the others, while the man of moderate means would doubtless not distinguish any one in preference to any other one, giving all of them some weight.

Cement Blocks Make a Cheap House—Of all of the forms which concrete construction is susceptible to, none makes a house cost less than concrete blocks. The mold for the blocks once made, they may be poured and allowed to set, at any leisure moment. Then, when enough have been made to allow of starting on the building, they may be laid up just like bricks, using the same cement as a mortar. This method of constructing a house fits into the average man's lack of much time on any one day, but a few hours each day, so well as to fit the cement block to the low priced, owner-built garage. The mold need not present any difficulty, nor the individual block construction. The same would apply to the laying of the blocks, no tools being needed except a trowel, a straight-edge, and a spirit level. The four walls done, the roof and other parts become a very simple carpenter's job.

At the bottom of the previous page is to be found a picture of a one-car cement block garage, as photographed by the writer. This is located on the Braircliff road, some miles north of New York City. The size is very close to car size, being but 12 ft. by 18 ft. outside measurements. Since the blocks are usually made 6 in. thick, this would make the inside measurements each a foot less, or 11 ft. wide by 17 ft. long. The double door is large, and hung on three big hinges. The windows are small, and few in number—one on each side only—but in the matter of light, the door helps out, having a large window in each part of its upper half.

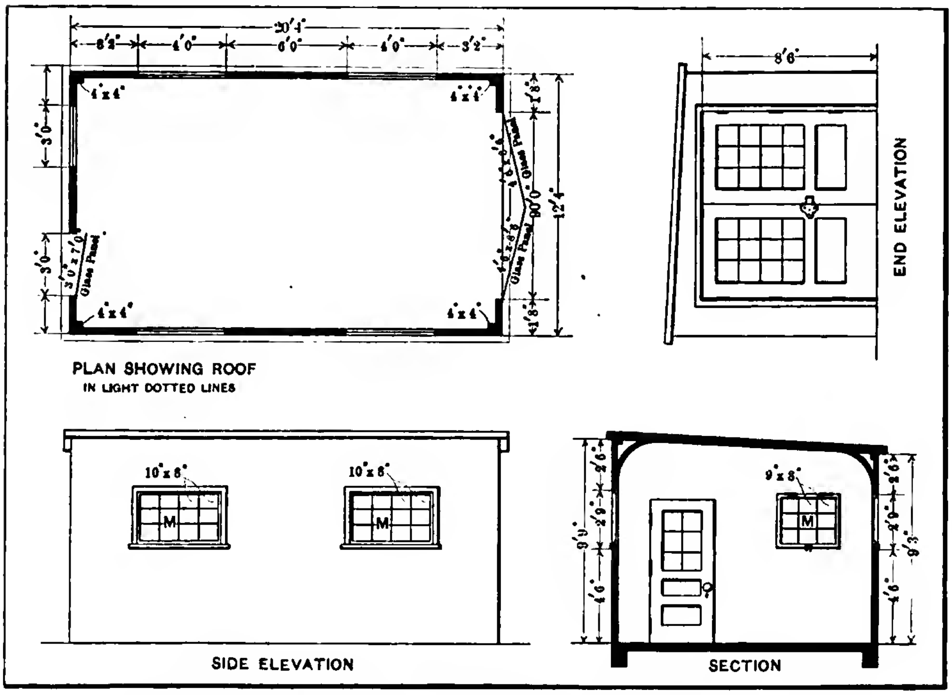
Wood forms the material of the roof, but it is covered with a light weight sheet iron, corrugated. The latter helps in the flowing down of water after a rain storm, as does, also, the rather steep pitch of the roof. Along the bottom edges, a neat gutter is placed to carry off the water in preference to letting it drip. In connection with what has been said previously about ease of ornamentation of concrete structures, attention is called to the ornamental lintels and sills for both doors and windows, as well as the watertable around the base. This latter helps very much to give this amateur attempt a finished appearance.

Elsewhere on this page is shown another small, one-car, concrete garage. This one, however, is located far from the other, being in Detroit. Not only is it located there, but it was designed in that city as well, being a Kahn job.

All Concrete, Roof and All—This garage presents many unusual features, not the least of which is the fact that the whole structure if of concrete, roof, floors, walls and all. This is what is known as reinforced concrete, metal bars or shapes being set into the concrete to give the whole more strength, and greater permanence. Considering the two materials, the thickness may be said to be 2 inches. Strange as it may seem the roof thickness is slightly greater than this.

The metal used as a base for the concrete, in this case is a special form of metal lath, known by the trade name of Hy-Rib. This is an obtruded sheet metal, the obtrusions projecting alternately to one side and then to the other. More than this, between the two are very narrow slots, which pass completely through. To use this metal, it may be nailed or tacked upon any kind of wood framework, and is then ready to have the cement applied. It is recommended by the makers that this be applied on the inside first. This feature of the material lends itself well to the construction of a garage, for with the inside completely plastered—the cement being made thin like plaster, and applied in the same manner with a trowel, or long flat smooth instrument—the outside frames may be removed.

When this has been done, and it may be done with perfect safety, as soon as the cement has set, the outside may be plastered up in the same manner. Since plastering is not a very hard, although a dirty job, anyone may do the work of erecting a garage of this kind. More than that, the skeleton framework being so very simple, any-



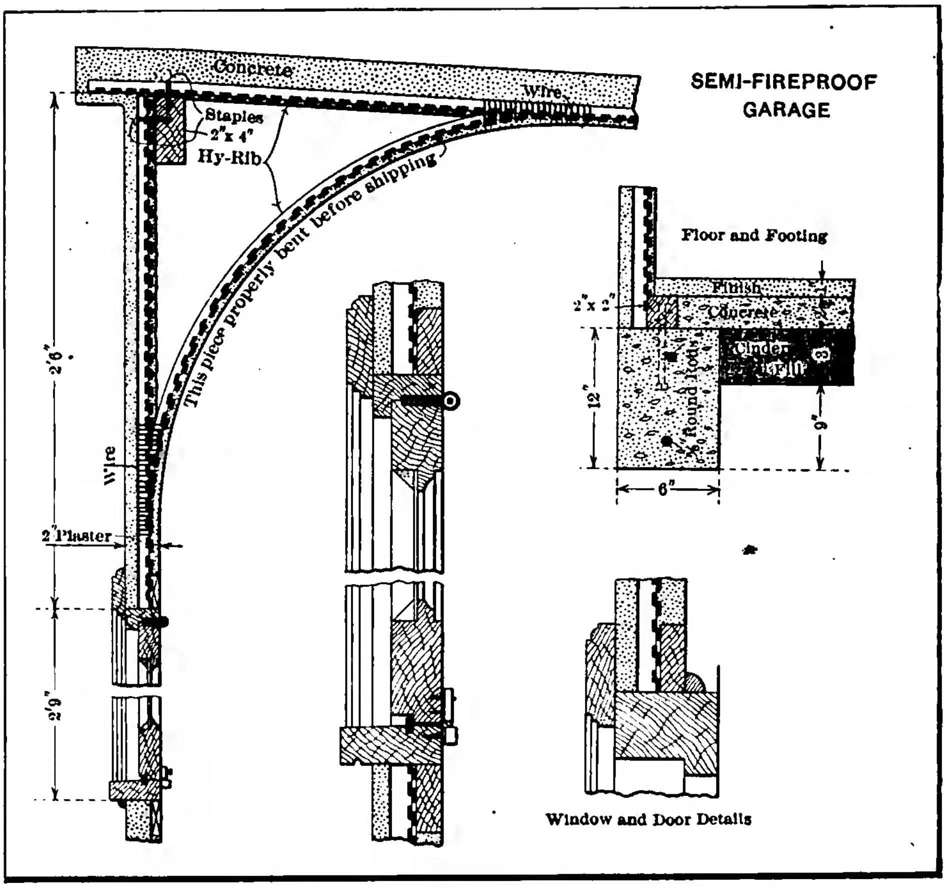
Plans from Which Schlesinger Garage Was Constructed, Slightly Changed one may do the work of erecting that, as well, if so inclined.

In the photograph, one of the long sides is shown. By consulting the plans of this garage shown on this page, it will be noticed that the shape is that of a rectangle, the long side being 20 ft. 4 in. in extent, which means just under 20 ft. inside. The short dimension is 12 ft. 4 in. outside or just under 12 ft. inside. The plans call for two windows on each of the long sides, with a window and family door at one end, and the big, double car door at the other. In the picture it will be seen that this design is susceptible to several changes, without materially altering the whole effect. Thus, the one illustrated has the family door located on the inner long side, for the simple reason that it occupied the whole width of a narrow city lot. This same reason led to the omission of the single window in the end opposite to the door. The roof, too, differs, in that it rises to a peak just like any wooden roof, while the design calls for a uniform downward slope.

Design Lends Itself to Amateur Workers—Without a doubt, this sloping roof was so designed to facilitate the work of making the garage, particularly when done by amateurs. This single continuous slope would be much easier to frame up for, to say nothing of applying the cement to. And, after all, it is hard to see that the peaked shape, aside from being conventional, has any advantages.

Above is shown a number of the details of this design. The roof, for instance, is supported from the corners by a truss-like arrangement, which consists of a circular form of the metal under framing, upon which the usual inside sheathing of cement is placed. These special shapes are bent at the factory, at very little extra expense, but must be ordered in advance. The 2 by 4, used for the framing of the corner of roof and side wall, could not be removed on account of this inside plaster isolating it, and is shown in the original position. The window framing and the method of placing the same may be noticed, as well as the enlarged detail of the same. So, too, with the door. For flooring, a bed of cinders, 3 in. deep, was laid, rolled down so as to be solid, and over this was laid a concrete flooring 2 in. thick. Finally, to complete the floor in a workmanlike manner, a 1 in. top dressing of neat cement was laid. The 6 in. by 12 in. corner section of concrete represents the foundation, at least the only foundation the house had. This is strengthened and tied together by means of round iron rods, laid longitudinally. Bolts set into this before it had set were used to bolt the corner timbers, of 2 in. by 2 in. lumber, into place. These were left in.

Concrete Garage Including Living Rooms—At the bottom of this page, still another concrete garage is shown, this one being larger to the extent of embodying a few living rooms. This one, too, has a peaked roof, but the addition of the living rooms at the back, meaning an increase in the length in that direction of about 14 ft., gives the idea of a long sloping roof. The main room, to which the whole front of the house is given up, is 25 ft. 2 in. by 28 ft. wide, the whole width of the structure. Back of this, from right to left, are: bedroom, 9 ft. by 14 ft.; living room, 8 ft. 8 in. by 14 ft.; kitchen, bathroom, and coal supply shed. The living room arrangement is very good, and the whole would make a neat little home for a chauffeur with a small family, the man-of-all-work or other domestics.



Details of Semi-Fireproof One-Car Garage, Like the Schlesinger

Aside from its size, the automobile room in front is well arranged. There is a large pit, which has three steps leading down to the bottom of it, which serve as a convenient seat on some under-the-car work, as well as a means of ingress and egress from the pit. At the bottom is a drain, while around the room are many cupboards, a sink with running water, work bench, with vises and tools, as well as other conveniences.

The sliding doors shown in the photograph of this garage make a neater construction than the two-leaf, outward-swinging form shown on the plans for the Schlesinger building, but are rather more expensive. Their use involves a lower guide or track, and an upper rail, along which the doors run on rollers. It is possible for the skilful amateur to construct these for himself.

Garage in Cement, Combining Living Rooms

A FEW ASSORTED QUESTIONS

Editor THE AUTOMOBILE:

[2,087]—My tail lamp constantly jars out. Can you give me information about an oil that will burn in an ordinary kerosene lamp and not jar out, or a burner that can be used and which will not jar out?

If the stems of the valves on an automobile engine are worn so that the space between the valve stem and the valve lifter is one-eighth of an inch (1/8), what effect would this have on the power of the engine?

A mixture of gasoline and air, 1 to 5, according to a handbook, gives about the same power as a 1 to 9 mixture. If I understand this correctly, one gets more power out of the same gasoline at a weak mixture of 1 to 9 than 1 to 5, or are there other conditions that overcome this advantage?

Can you inform me if the acid used in the acid cure for tire repairs is acetic acid, and does it injure the rubber of the tire?

Would the valve stem shortage previously mentioned cause a pounding on hill climbing?

Can you give me the age which an automobile is expected to wear and run in good condition? Also, what repairs or parts are most likely to give out first and put the car in such shape that it would not be worth while to put it back into running order?

Nichols, Conn. W. T. K.

To answer your many questions in order, we have never heard of a lamp, burner or oil for an oil lamp which would not jar out as you describe under sufficient provocation. Your only hope, if you feel that you must have something different, lies in electric lights, which, properly installed upon the car, would include side lights and tail lamps as well as the more usual searchlights.

Relative to the second question, the large space between valve stem and lifter will not influence the power except indirectly, although it will make an engine very noisy. The way in which it will influence the power is this: when the adustment is used to reduce the space and with it the noise, the timing of the valves will be altered slightly, and this slight alteration may be such as to change the power. For instance, the engine might have a rather late exhaust closing, which the adjustment would make still later. This, then, would cause the motor to heat and thus lose power. Similarly, the adjustment for the inlet valves might cause them to close either too early, making the charge incomplete, or too late, so that some of the charge was lost, also making it incomplete.

As to your fifth question on the same subject, the pounding on hill climbing could only be caused by the changing of the adjustment as just described. That is, it would not result from the simple too-large space, as long as the space was left unchanged.

Your understanding of the power and economy of a weak mixture is correct, but the reason why this cannot be used at all times is that an engine will not pull up a hill in sand, broken stones or other hard going on a weak mixture. On those occasions one must use a rich mixture or the engine will quit. So it is that the economy of the 1 to 9 mixture cannot be utilized at all times. On page 750 of the October 28 issue of THE AUTOMOBILE, you will find something on the same subject which may interest you. The figures there given are in percentages, however, and for your personal use, we have reduced these percentages to ratios, as follows: 15 per cent. is a 1 to 5.66 ratio; 5.5 per cent. is 1 to 17.2; 4.0 per cent. is equal to 1 to 24.0; 1.9 per cent. is 1 to 51.6; and 2.4 per cent. is 1 to 40.6. These, however, refer to gasoline vapor, not gasoline liquid.

The acid used in the acid cure for tire repairs is not acetic acid, which is the principal constituent of vinegar. The acid used does not harm the rubber.

It is hard to say what age automobiles are supposed to reach. We can only give you some figures on ages of cars which we know to be correct. Thus, in Buffalo, N. Y., there are many old Pierce cars dating back more than five years. Of these there are quite a few of the 3 1-2 horsepower motorettes, which were built in 1902, and consequently are 7 1-2 years old. There are many of the 6 1-2 horsepower stanhopes and still more of the 8 horsepower stanhopes, built in 1903 and 1904, respectively, making them each 6 1-2 and 5 1-2 years old.

The writer has a close friend in Detroit who owns and still runs a single cylinder Packard. As this firm moved to Detroit in 1903, and built no single cylinders in the new shop, this car must date back to the Warren, O., plant, which means that it is from 6 1-2 to 7 1-2 years old. Again, the writer knows of an old two-cylinder Winton, built in 1902 or 1903, which is still doing yeoman service in Eastern Pennsylvania. This car, in fact, climbed a steep hill which automobilists ordinarily dodge, with five heavy passengers on board, without a particle of trouble. At the time this was done the car was five years old, and now is about 6 1-2 or 7 years.

As all of these cars were built early in the automobile business, before the advent of superior materials, and really before the days of very fine workmanship, it is reasonable to suppose that a good, modern, well-built car should last from ten years on up, according to the care it receives.

The repair parts necessary would also vary with the use, but, off hand, it would seem as if running gear parts and bearings would go first. Transmission and other gears see severe service and would doubtless follow the bearings, while such parts as cylinders, flywheel, crank and gear cases, frame, etc., should last indefinitely.

Of course, these cars have all had the benefit of careful driving and skilled attention whenever necessary. Such handling should be taken for granted in calculating the life, for an automobile is, after all, a piece of machinery, and should be treated as such to secure the best results. If you buy a 1910 model of reputable make, and treat it well, it should be running in 1920.

CENTRIFUGAL PUMP OUTPUT

Editor THE AUTOMOBILE:

[2,088]—In your article on radiators in the issue of October 21, speaking of centrifugal pumps, you say that in a certain test 680 r. p. m. was found to be the speed of impending delivery, and conclude that the quantity of water handled by the pump at any lower speed is negligible. However, in the cooling system of an automobile we have a closed circuit of water, and the only head to be dealt with is that due to friction, so I think it will be found that the pump handles a considerable amount of water even when the engine is running slowly. I drive a car in which the pump, of the centrifugal type, runs at about the same speed as the engine, and a vigorous circulation takes place when the engine is idling, close throttled.

EARLE A. RYDER.

Ithaca, N. Y.

Granting all that you say, because if the pump did not circulate some water at low speeds it would be dangerous to run the engine at those speeds, we still think that our remarks in the issue and article mentioned were perfectly correct. Since the lowest speed possible with a normal engine is 300 r. p. m., and in the usual case, even this is not approached, 400 being more nearly correct, it would appear as if the speed of pump previously mentioned has been closely approximated.

In this connection, we wish to call attention to the fact that not one person in a hundred can judge slow speeds of an automobile engine correctly. To prove this contention, we will cite an example. The writer knew a man engaged in automobile manufacturing, previous to two years of which he had been engaged in automobile repairing for about five years. This man built his own engine and claimed that it would run at as low a speed as 200 normally, and could be made to run at 160 if desired. The writer called his attention to the fact that the engine would not do this, and after much discussion a speed indicator was called into play. The very first time this showed 450 r. p. m. On the second trial with the engine apparently running much slower, and the manufacturer very confident, the figures were 435. The trials were continued for a whole day, and not once was this manufacturer able to go below 388, the low figure for the day's work. Yet he had been in the automobile business for about seven years.

Similarly, a driver who prided himself on the slow speed at which his engine would run, due to changes he had made in the throttle of the carbureter, was asked by the writer to run his engine as slowly as possible. When he had done so, and estimated the speed at "about 240 revolutions," the speed counter showed it to be 425. He hastened to make a few changes, and confidently asked to have it counted again, saying "it is running about 250 now." The counter figures were 410.

ANSWERED AND DISCUSSED

RELATION OF POWER: SPEED

Editor THE AUTOMOBILE:

[2,089]—I have a runabout of the high-wheel, solid-tire type, a standard make of its kind. Ordinarily it is a speedy and serviceable vehicle. It is rated 12 H. P., and by the formulas figures 13.5 H. P. Its weight is about 1,000 lbs. Recently my wife and I were crossing a bridge, and at the point of leaving the bridge there is rather a steep downgrade. At this place for a distance of two or three rods there had been spread a fresh coat of broken limestone five to eight inches deep. The stone had been spread but not rolled down. On going off the bridge down grade on the high speed, the engine stalled within a few feet of the end of the stone repair. Returning later, we took the obstruction up grade with the low speed, and with the throttle and spark as far advanced as it would bear. The machine stopped at about the middle. I had the humiliation of seeing two buggies, each drawn by one horse and each carrying two men, pass me with no great difficulty; also a cab with two horses, the driver and four passengers. With my wife at the wheel, I got out and pushed; and, although I am far from being a Hercules, we pulled up on the bridge and the trouble was over. A few minutes later the machine went up a long, steep grade on the high speed and without faltering. Now, wherein was the 12 H. P. engine at a disadvantage with the one and two actual horse-power buggies and carriage?

Columbus, O. A SUBSCRIBER.

The secret of your trouble in this case, the same as that of many other automobilists in similar cases, lies in the relation of power to speed. This sounds like a puzzle, but it is not. The torque (which is a technical name for turning force) of the motor is always the same at the same speed. This, however, is delivered to the wheels at varying speeds, and although you may not realize it you yourself appreciate that the torque is greatest at the slowest speed of the wheels. It is for this reason that you come down to low speed to climb hills or to pass through broken stone, gravel or the like, all of which are conditions that require a large torque.

Perhaps it will be more simple if put into figures. Thus, suppose that the engine develops 12 horsepower, as you say. Suppose, further, that at high speeds, equal to 12 miles per hour, the torque exerted at the wheels is 200 inch-pounds. Then suppose, further, that the low speed is just half of the high, or 6 miles per hour. At this speed of the vehicle, with the engine running just the same speed as before and developing just as much power, the torque at the wheels will have been increased to twice what it was before, or 400 inch-pounds.

Again, if it were possible to equip your car with a third, still lower speed of, say, half the present low speed, making the velocity of the vehicle at that speed 3 miles per hour, the torque at the wheels for the same engine power developed at the same engine speed would be twice the previous example, or 800 inch pounds.

This explains the failure of the machine in part to negotiate the gravel-covered road, that is, the lowest speed of the vehicle which your gearing allowed was not sufficiently low for the engine to pull the car through, as it would have done had you possessed another and still lower speed.

There is another side to this, and that is the ability of any animal to exert an unusual amount of power for a very short time, a thing which no machine, other than the electrical motor, can do without internal changes, and which very few machines can do with any kind of changes. That is to say, that machines have a fixed output, beyond which they cannot go, but the same is not true of animals.

So, it might be said with truth that the horse in question, under the urging of his driver, doubtless exerted many times the equivalent of one horsepower for the few short seconds occupied in passing through the stone pile.

The same thing is doubtless true of yourself, urged on by your humiliation, you doubtless exerted a power equivalent to several horsepower for the very few seconds in which you were pushing to help the engine along. Do not feel that this trouble is confined to your type of car alone; 40, 50 and 60 horsepower machines have been known to be stuck under similar situations, their gearing being such that under the unusually severe demands of, say, deep sand, the motor was unable to develop a torque at the wheels which was sufficient to pull the car out.

On the other hand, to gear the car down for these unusual requirements, that is, so low that no hill or sand would stop the car, would render the usual driving anything but pleasure, or else would call for a new type of gear box with five or six speeds, the last two being so low as to be practically a crawl. These would be emergency speeds, and the extra weight would have to be carried all of the time, for a possible use once a year. The question then arises, would this be worth while?

COLD WEATHER COMING

Editor THE AUTOMOBILE:

[2,090]—Will you kindly inform me whether a thin, light oil that will not congeal at zero can be used in the cooling system of an automobile having a water pump? Also, would the use of kerosene be practicable?

Boston. G. E. ROGERS.

The kerosene idea was taken up in last week's issue. We do not advise its use. Light mineral oil, of the grade known in the trade as refrigerating oil, makes a very good winter cooling medium. This is the oil used for ice-making machinery.

INJURIOUS EFFECT OF OIL

Editor THE AUTOMOBILE:

[2,091]—I have read with interest your remarks on non-freezing alcoholic mixtures for the radiators of motor cars during the cold weather. The principal and about only objection to the use of alcohol is its rapid evaporation, and I have thought that this might be overcome to some extent by putting a film of some light lubricating oil on top of the mixture in the radiator. I do not think that the oil would circulate and could therefore have no injurious effect on the rubber hose connections.

Have you any knowledge of this being tried, and would there be any objections to put a small amount of oil in the radiator as above suggested? H. L. D.

Nyack, N. Y.

As was brought out in answer to a letter last week, the principal trouble which oil in the cooling water causes is that due to reducing the radiating ability of the radiator. The oil forms a thin film over the whole surface of the radiator, and reduces the capacity of the latter to about one-third of its usual capacity. This is because oil is a poor conductor of heat, and also because of the thin layer of air which will be caught between the oil film and the metal, the latter being a non-conductor of heat. Since the cooling capacity of the radiator is figured very close so as to keep the weight down as low as possible, a reduction of two-thirds is serious.

The immediate result of this would be to make the motor heat up very quickly, since the heat could not be conducted away fast enough.

We have never heard of this being tried and certainly would not advise it.

Even if the aforementioned effect on the cooling ability of the radiator and therefore on the whole system was not as outlined above, how do you make out that the oil would not circulate and attack the various rubber connections? Certainly, even if the oil floated on the top of the water, when the latter circulated around through the water jackets the oil would not stay where you wished it to, but would circulate also, and nothing that you could do would prevent it.

MATERIALS FOR BALLOONS

Editor THE AUTOMOBILE:

[2,092]—Can you give me the address of a maker of gas bags for balloon purposes, or of materials which could be used for these things? H. J. NEWMAN.

Goshen, N. Y.

We cannot give you the name of any balloon makers, but several makers of cloth of a special weave for use in balloons and aeroplanes are available.

For this purpose, a fabric is necessary which combines strength and extreme light weight with waterproof qualities. Silk answers most of these, and so the basis of most of the special cloths is a silk. This is usually coated inside and out with a very thin coating of pure rubber.

Such a fabric is made and sold by the Continental Caoutchouc Company, the makers of the well-known Continental tires. Another maker is Glenn Curtiss, who is said to have invented a new fabric which excels all others. You can reach him at Hammondsport, N. Y.

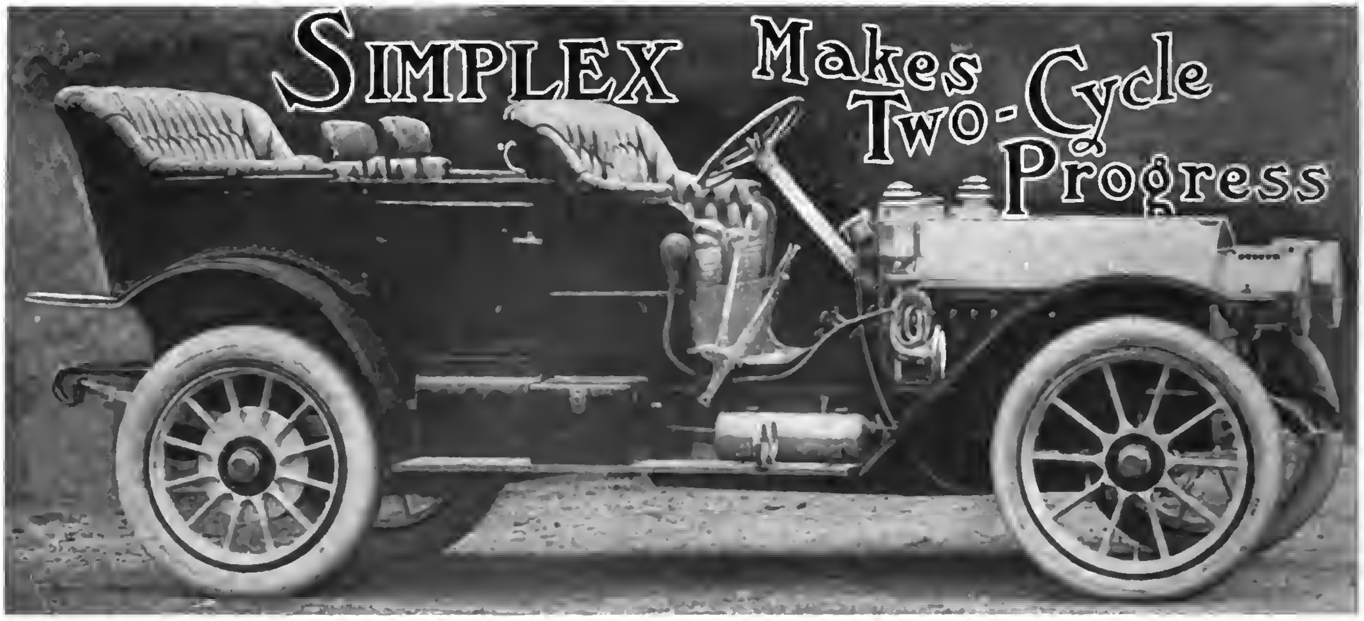

Fig. 1—Model 50 touring car with seven-passenger body, a wide entrance, flaring mud guards and a business-like get-up

MISHAWAKA, IND., Nov. 8—Differentiating between the fullest measure of success and a scant existence, so to speak, is attended by difficulties on occasions, due to a similarity of features and lack of exact knowledge. In discussing the two-cycle motor, as it is used in automobile work, this problem in differentiation becomes acute, and the only way, perhaps, to ascertain the bottom facts is to show what has been done.

It was but a few short years ago that designers were wont to claim that none but electric vehicles would ever reach a high level, and all forms of internal combustion motors were looked upon as far too complicated to be placed in the hands of average users of vehicles to use for transportation purposes. Fortunately, men who do things declined to be led by the nose, and they went right on experimenting with internal combustion motors, with the result that the success of the electric type of car was no more than assured when the gasoline type entered the race for popular favor.

Four-Cycle Motors Were Perfected First—The four-cycle type of motor offered the least resistance, and it reached a high state of perfection first. This is in spite of the added mechanical complication, which goes to show that it was not a question of mechanics at all. As might have been expected, it was easier to assure a competent firing charge in a four-cycle motor for the very reason that the mechanical displacement of the burnt charge is the surest way of scavenging.

This easy gain was a fortunate circumstance, considering the class of men who want "dividends" on efforts at once, but it was no proof of lack of ability of the two-cycle motor. As a matter of fact, the very class of men who jumped to the conclusion than only the electric would serve in the long run, repeated their short-sighted dictum when the four-cycle motor fought its way to recognition, and now that the two-cycle motor is commanding respect, these prognosticators will again have to bow to the type of man who works and struggles, the courage of sound conviction being the incentive.

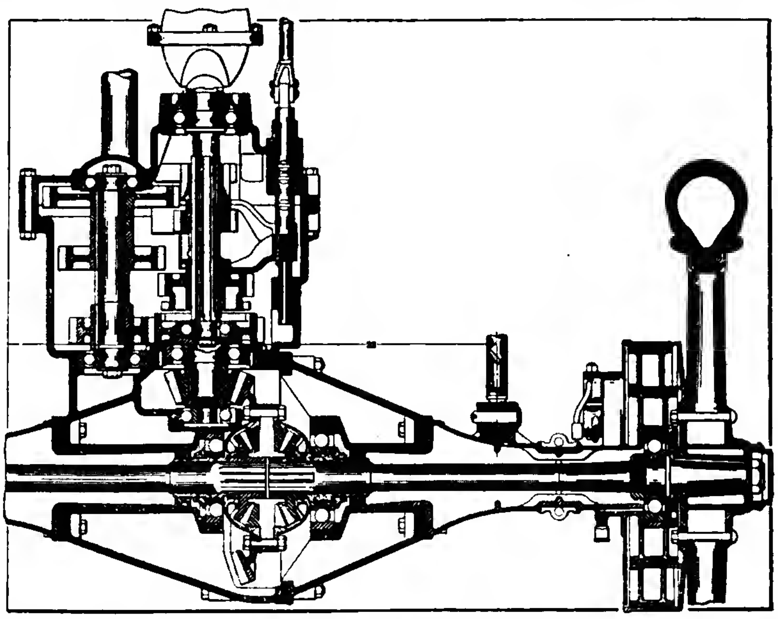

Fig. 2—Live rear axle with attached transmission, sectioned to show annular ball bearings, floating shafts, double brake drum and general details

Two-Cycle Three-Port Motor Offered Greatest Resistance—Strange to relate, the three-port type of motor, which is mechanically the most simple of all, offered by far the greatest resistance, thus again showing that mechanical problems were the least troublesome, and that the designer had to cope with many problems the nature of which were "thermodynamic," and to a vast extent speculative.

Many Failures Charged to Wrong Mechanism—When a car, as a whole, fails, the question is, what part of the car is responsible for the failure? Is it the motor, clutch, transmission, axles, wheels, tires, or does each unit contribute a quota? In the past it frequently happened that failure was due to lack of ability of the structure as a whole; each element contributed a share of the trouble, and the owner of the car, not knowing where to center responsibility, charged the whole of the failure to some one part, and why not the motor, especially if it differed from the general run of motors?

In this way many of the earlier four-cycle failures, so-called, were charged to the motor, when, in all truth, the chassis would not properly serve, even with electrical equipment for the motive power, and later on, when two-cycle efforts were made, it did not occur to any one to ascertain if the trouble was not due to inferior chassis construction, rather than for want of a good motor. These failures to discriminate as between the sources of trouble resulted in placing all of it on the relatively new unit, as the two-cycle motor, and delayed recognition of undoubted quality was a natural sequence, and to be expected.

Two-Cycle Motor Hampered by Environment—All the earlier applications of the two-cycle principle were in connection with boat propulsion, and single-cylinder motors were used in almost every case. In the single-cylinder type of motor it was not difficult to render the crankbox tight, and the primary compression which took place therein was not difficult of attainment. The little motors were so simple and they worked so well that thousands of them were designed and constructed, but, unfortunately, the class of workmanship was generally below a fitting standard, and when this class of work was put into multi-cylinder motors for use in automobiles, the motors failed, simply because they were mechanically incapable of sustaining in the more difficult service.

There is no doubt about the abstract ability of a steam engine, and yet, were many of the steam engines now being built mounted on the frame of a locomotive, they would fail in service. This illustration is apropos; failure, when it is encountered, may be due to a malapplication of a principle, rather than to the principle.

Simplex Three-Port Two-Cycle Motor—The three-port type of two-cycle motor is absolutely valveless; the mixture enters the crankbox through a third port; it is there compressed by the descending piston just as in the two-port type of two-cycle motor, and in both types of two-cycle motors, as well understood, every descending stroke of every piston (referring to a vertical type of automobile motor) is a power stroke. This cyclic relation must be appreciated to understand the reason for desiring to adopt the two-cycle principle; in a four-cycle (automobile) motor every second downward stroke is a power stroke.

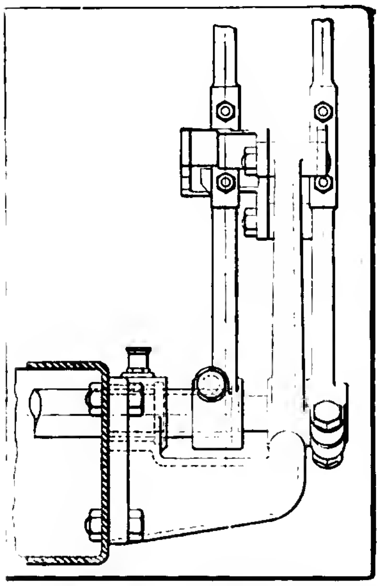

Fig. 4—Section of chassis frame just in front of side lever bracket

It will be understood, then, that a two-cycle motor, with either two or three ports, is designed to deliver twice as many power strokes per cylinder, per thousand revolutions of the crankshaft, as can be realized from a four-cycle motor of the same number of cylinders. Obviously, with the same bore and stroke of cylinder and piston, respectively, if the mean effective pressure can be made the same in the two-cycle as it is in the four-cycle type of motor, the power which can be delivered from the two-cycle motor will be double that of the other, per thousand revolutions of the crankshaft, in common time. To accomplish this has always been the aim of the two-cycle designer, and an immense amount of energy has been expended on the subject by innumerable inventors.

It has never been shown that the two-cycle type of motor is capable of delivering double the power realized from its cousin, the four; the mean effective pressure is not the same in both, and it is even a question if some of the inferior designs of two-cycle motors are capable of delivering as much power as is usually realized from average designs of four-cycle motors.

Taking the motor as made at the plant of the Simplex Motor Car Company, at Mishawaka, Ind., as an example, it will be possible to discuss the subject further, and with this concrete example at hand, determine with far greater certainty the facts

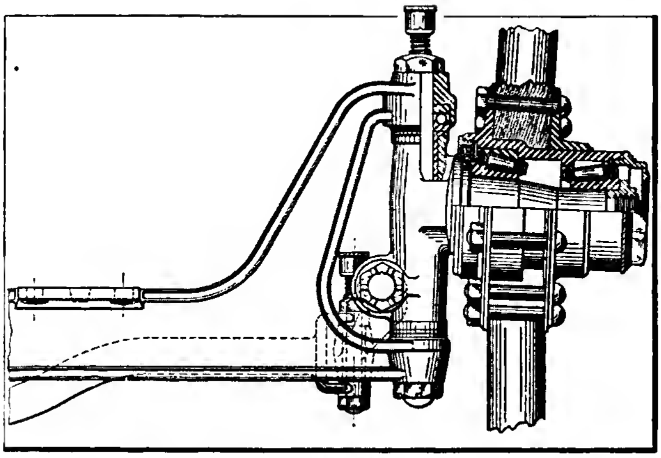

Fig. 3—I-section front axle, looking at the front, cut away to illustrate Timken roller bearings in front wheel hub and ball bearing knuckles

and the trend. The car, as made by this company, is shown in Fig. 1, the specifications of which are as follows:

SPECIFICATIONS OF AMERICAN SIMPLEX AUTOMOBILE

Data of the Motor	
Number of cylinders	4
Bore	5-in.
Stroke	5-in.
Normal speed (revolutions per minute)	900
Rated horse power	50
Ignition	Dual
Principal source of electricity	Magneto
Emergency source of elecricity	Storage battery
Carburetion	Automatic
Cooling (centrifugal pump)	Water
Lubrication	Force and splash
Cylinders	Gray iron
Crankcase	Aluminum
Data of the Chassis	
Wheelbase (touring)	117-in.
Wheels (wood)	Artillery
Tires (front)	36 x 4 in.
Tires (rear)	36 x 5 in.
Chassis frame	Channel steel
Steering gear	Gemmer
Springs, front and rear	Semi-elliptic
Front axle	I section
Rear axle	Live
Front wheel bearings	Timken
Rear wheel bearings (D.W.F.)	Hess-Bright
Transmission	Shaft drive
Speeds	3 forward; 1 reverse
Location of transmission gear	Suspended from rear axle
Clutch	Disc
Clutch facings	Steel on gray iron
Clutch location	In flywheel
Brakes; two sets (constricting)	Drums on rear wheels
Muffler	Special design
Spark and throttle levers	On steering wheel

Note—The specifications as above given, while they apply to the touring car, are, with slight exception, applicable to the several other models, as close-couple, limousine, and touring roadster.

Separate the Chassis from the Motor—An intelligent discussion of the merits of the valveless two-cycle motor will not be possible unless it can first be shown that the chassis and the remaining units are competent, free from trouble, and by a system of elimination bring all troubles home to the motor, if such there are.

Since the live rear axle and the transmission are important members, capable of inducing a deal of trouble if they are not rightly made, it is proposed to present reproductions of working drawings and, to the greatest

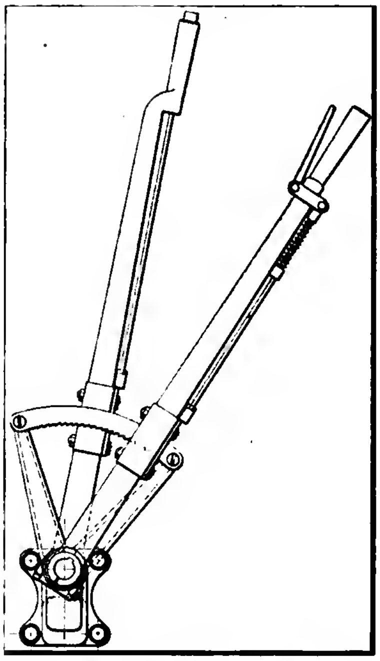

Fig. 5—Plan of side levers, quadrant, and details of design

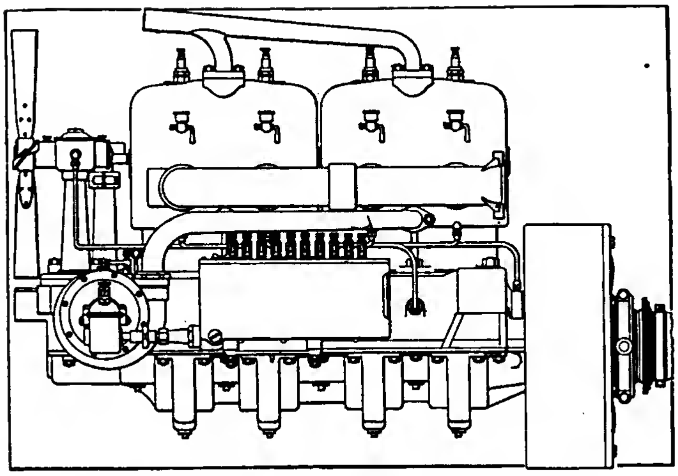

Fig. 6—Elevation of the two-cycle three-port motor with oiler exposed, fan in place and flywheel covering the clutch

possible extent, show that trouble from this source is scarcely a remote contingency. Fig. 2 shows these important members in section, with the left wheel and part of the axle broken away, since both sides are symmetrical, and the reproduction will be on a larger scale, hence more clear. The live shaft floats on Hess-Bright ball bearings; the hub of the wheel is drawn up on a taper, and the termination in the differential gear for each shaft is enlarged and fluted, thus assuring competence and ease of assembling. The wheel is prevented from floating off by the closure ring of the large annular type bearing, just inside of the hub of the wheel, on each side, nested within the drum of the brakes.

The wheels are made with large section spokes, of which there are twelve, and the brake-drums are bolted to the hub-flanges, provided with mud excluders, and each set of brakes is provided with individual flanges. The spring perches rotate on bearings, hence there is no binding tendency when the springs

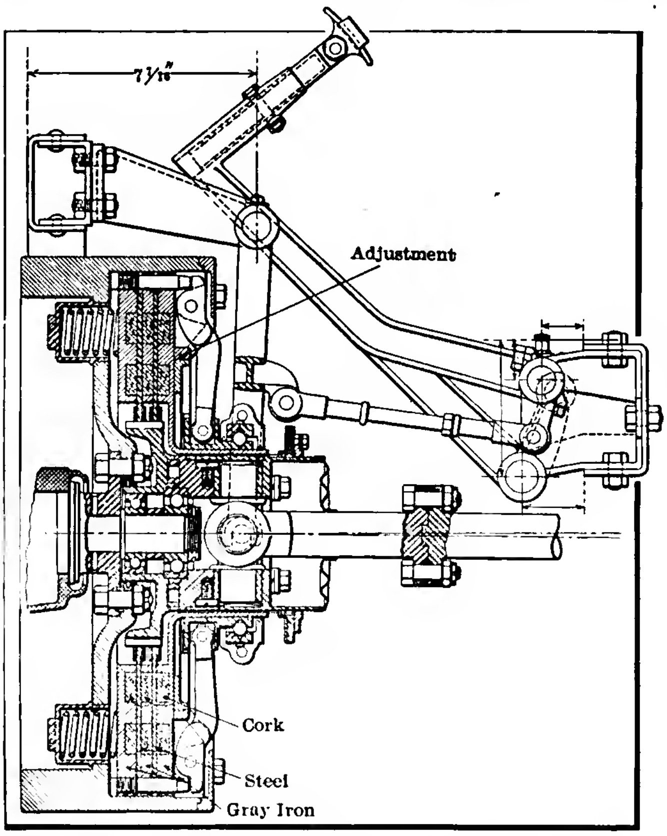

Fig. 7—Sectional view of flywheel and clutch, illustrating multiple disc clutch, controlling mechanism and details

deflect, and inside of the springs, at a point of vantage, the radius rods are anchored, they being of nickel-steel tubing, and the bearings at the anchorage are provided with ample surface.

The differential gears are of the bevel type, made of special (low metalloid) 15 carbon steel, cemented and hardened. The differential gears and housing are provided with liberal bearings, and the bevel drive, the gear of which is bolted to the housing, is of liberal proportions, with annular ball bearings at every point, including an outboard bearing for the pinion. Closure rings, with three grooves, prevent lubricant from migrating out, and silt of the road is debarred from entering.

Transmission Gears of Great Strength—The aluminum housing for the transmission gears engages the housing of the live rear axle in such a way as to form an integral part thereof, and short shafts, of liberal diameter (drive and lay), are suspended in annular ball bearings. The direct drive is worked out in a manner to be commended, a 24-teeth internal gear being used for the purpose, and a No. 406 Hess-Bright ball bearing is placed at the end of the shaft, within the gear, to take the load. The materials used are of the best obtainable in alloy steel.

Front Axle Up to a Fitting Standard—Referring to Fig. 3, it will be observed that the front axle is of the I-section, forged in one piece, and the knuckles are also die forgings of special steel, annealed and accurately machined. The knuckles are long, provided with liberal bearings, and the thrust is taken on a ball bearing at the top. The front road wheels are of special design, with liberal spokes, and, like the rear wheels, the wood is second-growth hickory, seasoned and selected with a view to casting out "bastard" and defective wood. Timken roller bearings are used in the front road wheels, it being the desire to thus provide for thrust.

The steering links are of nickel-steel tubing; balls for ball and socket joints are large, securely placed and adjustable. The steering arm attaches to the knuckle in a secure and proper manner, and the shape is such that the links are nested above and to the rear, out of harm's way.

Other Substantial Chassis Evidences—The chassis frame, as shown in section in Fig. 4, is 5 x 2 x 3-16 inches, of a special selection of material, and affords a wealth of rigidity for the intended purpose. Despite this ample frame, the machinery is securely mounted and universal joints are placed to take the effect of road inequalities at every point, one of which is shown at the end of the shaft in Fig. 2.

Referring again to Fig. 4, it will be observed that the side levers are securely related to the frame, an ample bracket (made of a steel casting) being used for the purpose. The levers, which are of a nice design, are depicted to better advantage in Fig. 5. These levers are of die-forged steel, fashioned to enhance the general appearance of the car, as well as to serve for sliding the gears and applying the emergency brakes. It would be possible to show, by means of additional working drawings, that the chassis and its relating units are quite up to the most fitting requirement, and since the whole car is made at the most Simplex plant, under the direction of the one corps of engineers, uniformity is a reasonable expectation.

Motor Is Not Handicapped—Any further discussion of the motor will be with the understanding that it is not required to shoulder the blame of an incompetent chassis, and under such conditions if it fails to perform in a satisfactory manner it is the motor that will have to serve for the explanation.

The general design of the motor is shown in Fig. 6, and owing to the entire absence of valves, it looks quite different from motors in general. The flywheel is rather large as it shows, but glancing at Fig. 7 will suffice to indicate the reason. The clutch, which is housed in the flywheel, is of the multiple disc type, with steel discs, of which there are two, pressed by means of four springs against cork inserts in gray-iron mates. The maximum spring pressure is about 200 pounds, and by means of an adjustment, as shown, the discs may be brought into more intimate relation if, perchance, wear creeps in.

A universal joint is placed within a shell in front of an assembling joint in the shaft, and a distance rod takes all pressure when the foot pedal is pressed to relieve the clutch. The whole mechanism is housed in the flywheel, and the face of the same is more than usual on this account, although the actual weight of the flywheel is well within the realm of good practice.

Fan and Starting Crank Details—At the front end of the motor the fan used to draw cool air through the radiator is fashioned in conjunction with a pedestal, which also serves to house the fanshaft, which engages a lateral shaft through a spiral gear, thus eliminating the belt as ordinarily used to drive the fan. The fan rotates on ball bearings, is placed horizontal, and a bevel drive makes the right-angle transmission. The starting crank emerges from the casing, and the driving jaws are enclosed in the housing. The crank is broken off, but the detail is sufficiently clear to indicate care in the designing, and that the two-cycle principle is not harassed at this end of the motor.

How the Accessories Are Arranged—Glancing at Fig. 9, the cross-shaft previously referred to will be seen, and the accessories are driven through this shaft, which takes its rotative ability from the crankshaft by means of a spiral gear system, with one member keyed on to the crankshaft as indicated. The water circulation pump is of the centrifugal type, and its shaft passes in through the wall of the housing and engages a safety (flexible) joint, through which the power is obtained.

The timer passes up, is driven by a bevel gear set, and is in an accessible position when the power plant is placed in the chassis. The magneto drive is shown to the left, and a sliding (floating) shaft, equipped with a bevel drive at the magneto end, engages with the spark advancing mechanism, a section of which is clearly given. The whole equipment is suitably enclosed, grease cups are provided at all points and, in view of the methods employed, noiselessness of performance is a normal expectation.

Crankshaft Tells Its Own Tale—Referring to the crankshaft, Fig. 10, it is to note that it is relatively light, is drilled out with 7-8-inch holes, with an outside diameter (uniformly) of two inches. The cheeks are quite thin, 11-16 inches, and the arrangement of the cranks is that of a pair of two cylinder crankshafts (rotated 180 degrees) with an angular displacement of 90 degrees between the pair. The firing order is 1-3-2-4, and in view of the unbalanced arrangement of the cranks, balancing discs are placed over the throws.

The use of balancing weights may seem to be disadvantageous, but it must be remembered that the crankcase compression must be maintained as high as possible (about seven pounds in this motor), and the weights are used to fill up the crankbox, as well as to balance the crankshaft, it being the experience that the crankshaft is not sufficiently out of balance to give any trouble at all at the best power speed of the motor.

The crankbox compression is brought up to the high point named by having the space quite completely filled, and tightness, which is difficult to attain, is brought about by means of split, mitered, packing rings, with springs behind them, and since they are ground, and press against ground faces of the cheeks of the crankshaft, they are not only tight, but experience has shown that they will stay so.

To afford bearing surface for the packing rings, the cheeks of the crankshaft are made thin and wide, and in view of the continuous but relatively smooth series of twisting moments afforded by the motor, the crankshaft, as designed, serves the purpose perfectly, and of the considerable number now in use a failure is as yet to be recorded.

In this very crankshaft construction is to be found a large part of the success of the motor; it has long been known that two-cycle motors can be made to work if the crankbox compression is maintained,

(A) At or near seven pounds per square inch;

(B) The same in every chamber of the crankbox;

(C) Despite the inroads of service long continued.

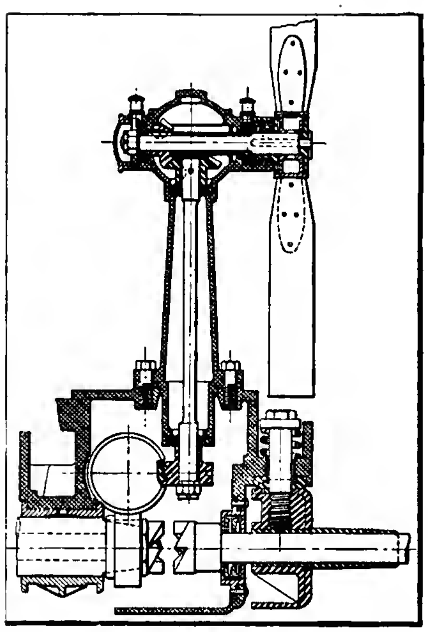

Fig. 8—Section of front end of motor and fan, presenting method of driving and details of the starting crank

Power Delivered Is Very Satisfactory—The A. L. A. M. rating of a 5 x 5-inch, bore and stroke respectively, four-cylinder, water-cooled, four-cycle motor is determined as follows, remembering that this is approximate, for comparison:

$$\text{Horsepower} = \frac{d^2 N}{2.5} = \frac{5^2 \times 4}{2.5} = 40$$

The above is about all that can be expected from a motor of the conventional order, and, taking the average of motors, it is too much to say that all will do so well.

The two-cycle motor, as here described, claims the distinction of delivering (under the same conditions of test) between 50 and 65 horsepower; it is better to consider a range of the delivery figures, perhaps, than to state the maximum.

All that has been shown so far is that the design is on a high plane, the workmanship is that of a well-equipped shop, and a single, well-directed corps of engineers has the whole situation in hand.

One of the points to be taken cognizance of is the high compression of the cylinders, it being about 90 pounds per square inch, absolute. All the cylinders are ground, even over the domes, which are flat, in order to assure equality of compression in the respective cylinders. Then, the pistons are provided with deflectors that could only have been arrived at after much experimenting. The ports, of which there are four for the inlet and exhaust, are wide and about 1 1-4 inch in depth, and the radius of

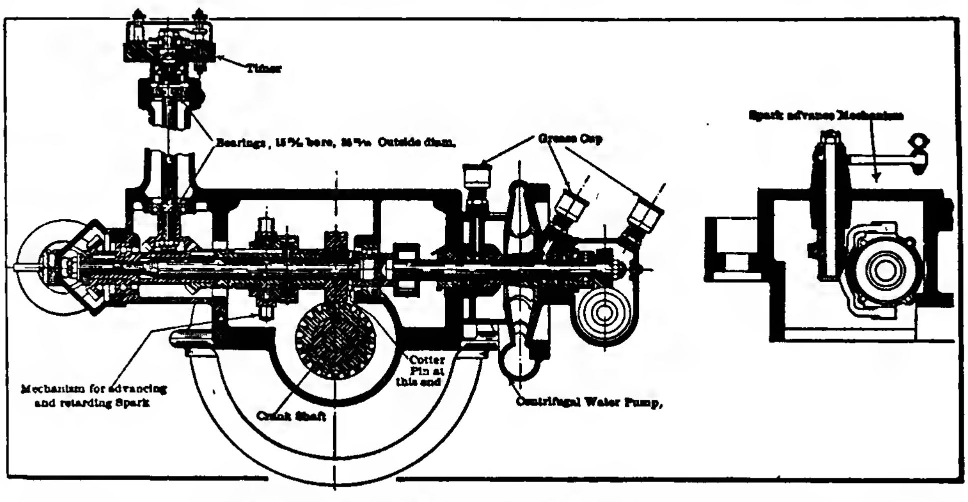

Fig. 9—Section of crankcase at lateral shaft, depicting water pump in section, drive for magneto and method of advancing the spark

the deflector, as it sweeps away from the cylinder wall, is about 1 1-2 inch.

Between each port there is a baffle fin on the deflector, the function of which is to prevent the incoming mixture from sneaking around over the surface of the piston head and mingling with the escaping exhaust. The baffle is on the inlet side, and the exhaust ports are about half of the depth of the inlet ports wider, so that the exhaust opens early, and the terminal pressure is very much reduced when the inlet ports are uncovered by the piston.

The inertia of the exhaust under the given conditions of escape is sufficient to prevent crankbox fouling, and the bridges between the exhaust ports are water cooled. The piston rings are about of the same dimensions as those used in good water-cooled motors of the four-cycle type, and it has been determined that they are less likely to fall into the ports than they would be were they as wide as the ports. The bridges serve to guide the rings by the ports, and it cannot be discovered that there is any trouble attached to this detail.

The transfer ports are much restricted, it being a matter of skill to fix upon the minimum possible cubical volume of them; any excess would serve as a detriment, since the crankbox compression would be reduced thereby.

Other Details Contribute to Success—The idea involved in maintaining a high compression is to make the mixture as inflammable as possible, taking into account the possibility of incomplete scavenging, due to the short time the gas has to pass out, especially when the speed of the motor is high, it having been determined that even 1,800 revolutions per minute is well within the range of practice. Even if the mixture is contaminated, if the compression is increased to match, it will burn readily. To add to this assurance, the spark is so contrived that it may be advanced as much as 60 degrees; in four-cycle work the spark is rarely advanced more than 38 degrees.

In order to be able to advance the spark fully 60 degrees, the mechanism, as shown in Fig. 9, was contrived, and it offers the advantage of bringing the armature of the magneto in the position of maximum energy at all points in the range.

Some Conclusions to Be Reached—Instead of following in the beaten path of four-cycle designers, if success is to reward two-cycle efforts it seems to be necessary to depart from them sufficiently to satisfy a series of modifications of the laws which govern the situation, among which the following is a resumé:

(A) The crankbox compression must be maintained with great precision between the respective chambers.

(B) The cylinder compression must be high enough to assure that even an inferior mixture will ignite and burn with sufficient speed to deliver its energy to the receding piston before it reaches the end of the stroke.

(C) The ignition system must be contrived with a considerable increase of the range of spark advance, in order to ignite slow-burning mixtures in time to take advantage of the energy component.

(D) The carbureter, especially in three-port motors, must be particularly capable, and in the case in point it was necessary to utilize the automatic principle and divers modifications of common practice.

A Fallacy Seems to Be Disclosed—Just because there are no valves required on a two-cycle motor, many embryo autoists came to the conclusion that it would cost next to nothing to build a good automobile; they failed to remember that the motor represents only about 25 per cent. of the whole undertaking, and it did not occur to them that motors are quite well behaved, as a rule.

In going into the matter with this idea of simplicity, they made the chassis, transmission, and other parts so simple that they failed to work, and then, not being capable of analyzing the trouble, it was a simple thing to apply the faults of construction to the motor and to relieve their pent-up feelings, cry it from the housetops. In the meantime, with a well-designed and constructed chassis, capable of serving with any kind of a motor that will deliver enough power, it has been found that a two-cycle motor, without any valves at all, is capable of doing the work reliably, and since there are double the number of twisting moments in a given time (comparing with a four-cycle motor), the power is delivered with the facility of a continuous flow, and the actual fiber strain of the members of the motor and the chassis is reduced.

Great Southern Incorporates—Articles of incorporation have been filed by the Great Southern Automobile Company, of Birmingham, Ala., which will erect a plant and manufacture cars at Ensley, near that city. The authorized capital stock is $100,000, of which $93,000 is subscribed. The officers are E. F. Enslen, president; Ike Adler, vice-president; John Kyser, secretary and treasurer, and E. F. Enslen, Jr., general manager.

ROAD SIGNS in Europe

By *Francis Miltoun*

CROSS ROADS

THANK-YOU-MA'AMS

GRADE CROSSING

DANGEROUS TURNS

PARIS, Nov. 12—The Touring Club de France, ever in the fore with innovations for the benefit of "le tourisme" in general and touring in France in particular, has already put out a number of the new "Signals for Road Obstacles" adopted by the recent "Conference Internationale de la Route" held in Paris.

Certainly the good work done by the Touring Club de France in the past shows no falling off in the legibility and accessibility of these really readable danger signals which are already being put into place at the right of the road, mounted on posts ten feet in height, and placed 250 meters before the obstacles. The automobilist who runs may read, and not be obliged to slow down and even shin up a pole to read the rather dim and altogether inefficient cast-iron governmental signboards in France.

These governmental sign-boards have in many cases already been supplemented by still more legible ones erected by the care and at the expense of the Touring Club de France on most of the international highways leading from Paris to the frontiers. They give primarily the termini of the route, as Paris—Geneve, and the distance from either end; then, in the largest letters of all, the name of the town near which it is placed, and, finally, the nearest large town in either direction. Of all useful and readable signboards to be found in any land these recently erected by the omnific T. C. F. are certainly the best planned and the most useful.

There is another class of sign-boards frequently met with in France that visiting automobiles often ignore and those are the "Octroi" signs at the entrance to all cities, and most towns and villages. In most cases a stop is compulsory, and to refuse to do so, when hailed by the official, is a misdemeanor, for which one pays in hard cash. It is an annoyance, to be sure, and many times ridiculous, but it is the law. Usually one declares that he has nothing on which to pay, though if you are a resident of the town, and are bringing home a dozen eggs from some friend's country place, a chicken, a rabbit, or even a bottle of wine, you give up a franc or more so that the dealers in that particular town who might have sold you the same merchandise are not put to a disadvantage. The French government is paternal in all things, but the very minute care which it bestows upon certain classes of its citizens make other classes mad neverthcless, and justly.

When one is held up at the gates of Paris and made to pay a tax on the gasoline and oil which he has in the reservoirs of his automobile a protest is justifiable. But you pay just the same, even if you are only a stranger going through.

Another road sign in France that one had best observe is that which holds the speed of automobiles down to a paltry twelve, ten, or even eight kilometers an hour through some crowded bailiwick. If you are a stranger, without a French residence, you may be held up on the spot for a "Contravention" and made to pay up. The fine will perhaps be comparatively small, but you will be kept in limbo, or your automobile will, which is the same thing, while the wheel of the law turns slowly on its axis and twenty-four or forty-eight hours spent in some dull little French town—seven of you, perhaps, in your big touring car—will make the cost come high, to say nothing of the fact that you will have to smoke the ordinary "Caporal," which is about the only tobacco purveyed in the small town, and drink warm, sticky, varnishy drinks on the café terrace half eaten up with flies while you are waiting.

There is another class of welcome signs which one sees distributed all over France, those of the Touring Club and the Automobile Club denoting hotels affiliated therewith, and again there are the signs of the big tire companies, which at the risk of being accused of giving a free advertisement, a couple of examples are given here, and very welcome the sight of one or the other of them may be on occasion. You all know that!

"Route Barré" is another sign not so welcome, but as it usually comes about half a mile before you find a new-made road, with its rough stones unrolled, you have time to prepare for the worst and are not on top of it without warning, as frequently happens in England. In general the road-makers in France work most intelligently and are not supposed to cover all the roadway at one time but leave a part of the road open for traffic. This is due to the energetic campaign which has been carried on by the Touring Club de France, and the Ponts et Chaussés, who has the road-making in charge, has sent strict orders abroad that the rule is to leave a part of the road open while another portion is being remade. Is there another country in the world where so

Two Road Signs Good to See in La Belle France

TWO SUBURBAN PARIS KILOMETRE STONES

much is being done, in the actual making and caring of roads, to make the automobilist happy? The writer thinks not.

Just now there is a new project on foot to make a new mountain highway to run from Lake Geneva to the Mediterranean, and as sponsor we learn that the Touring Club de France is back of it. There's a public-spirited body for you! Why is there not a similar institution in America, national in spirit, patriotic in a general, not a local, sense, and wealthy enough to endow any project for the benefit of touring with the funds necessary to set the ball a-rolling. After that it's easy; then local bodies come in and give their aid; some great resort en route may contribute a good round sum for the benefits that will accrue, the local automobile clubs can co-operate, and mayhap some Roi de Petrole or Prince d'Acier may endow the project as they have universities and institutions. The thing is worth looking into by all Americans who believe the new locomotion has come to stay—and who does not, save the aeroplanists?

FRENCH GOVERNMENT TOURING OFFICE

Paris, Nov. 3—France realizes that touring, by automobile or otherwise, is worth encouraging as a business proposition. Possessing good roads, natural beauty and historical sites in abundance, it is worth while to make them known and to encourage visitors both from home and abroad. With this object in view, Minister of Public Works Millerand has announced his intention of forming a government touring office, of which he will be the president, with a board of directors composed of the leaders of automobile and touring associations, representatives of hotel proprietors, railroad companies and financiers.

The object of the touring office, which will have government funds and yet be self-contained, will be to encourage touring by all possible means. Contrary to what might at first be expected, there will be no clashing with the work of the Touring Club of France or the touring department of the Automobile Club of France. On the contrary, it will be possible for these two bodies to extend their field of usefulness, for whereas formerly their effort was limited, owing to their inability to interfere with government departments, they have now a special branch of the government to carry through improvement schemes which they may formulate. An example of this is found in an improved system of mileposts which it was desired to adopt in France. The touring department of the Automobile Club of France worked the scheme out, it met with the approvement of all, including the government, but could not be put into use owing to the inertia of the particular government department involved. There are many other schemes that have been devised by the Touring Club of France for the benefit of all tourists and road travelers which will be carried to completion now that there is a government department to help.

NEW TAXICAB REGULATIONS IN PARIS

Paris, Nov. 3—Heavy fines and imprisonment no longer threaten Paris taxicab drivers who run with a smoky exhaust, or allow their rear light to be blown out. Drivers in the French metropolis have long been unfettered by a speed limit, the police recognizing that all the public needed was protection from the reckless driver, and not a stereotyped rate of speed, regardless of conditions.

Automobilists, and especially taxicab drivers, have been specially troubled, however, by the regulation making it an offense to emit smoke from the exhaust pipe and to run without a rear light. The first offense meant a fine, the second ditto, and the third a day in jail. For some time taxicab drivers have been kicking, and have kicked so effectively that special instructions have now been given to the police. The sergent de ville can stop any vehicle emitting smoke and, if without passengers, request the driver to draw off the excess oil causing a dirty exhaust. If there are passengers the driver can remedy the smoke nuisance on obtaining their permission to stop for this purpose. If the oil can be drawn off immediately and the smoking stopped, no summons will be issued. If the driver refuses to stop his engine smoking, or if the passengers refuse to allow him to stop for this purpose, a fine will almost certainly follow.

Instead of just jotting down the number of a car without a rear light, the Parisian policeman will first of all request that it be lighted. If the driver refuses to do this, police court proceedings will be the outcome. It is no longer allowed to take a car number and issue a summons for any offense without at the same time calling upon the driver to stop. If the driver refuses to hear the police whistle, his employer will be communicated with and the man called upon to give an explanation before proceedings are taken. This will make it impossible for summonses to be issued on wrong numbers, as so frequently happens.

Despite the changes, Paris taxicab drivers are not altogether satisfied. They maintain that imprisonment should be abolished entirely for the mere breaking of road regulations not coming under the criminal code. Unless this is done within a very brief period, they threaten to get up a huge demonstration. They have already given proof of their ability in this direction by serenading Judge Hamelin, who has passed most of the sentences of imprisonment, with the noise of several hundred hooters and the boom of the open exhaust. The outburst led to wholesale arrests, but as none were maintained it is evident that a higher authority than Judge Hamelin had interfered.

When horseflesh was in its glory, a certain number of individuals earned a livelihood by watching the cab horses while their drivers were in the shelter or eating a meal in a nearby restaurant. Since the introduction of the taxicab the horse tender has had to learn a new business. At every stand in the city is now stationed an ex-horse tender, whose business it is to close up the line as cabs move away, to trim lamps and generally make himself useful. If the ground is level or on a downgrade, the tender merely releases the brake and pushes the vehicle along until the line is closed up. If it is on a slope, however, he starts the engine and slips in the low gear without taking out clutch, runs alongside, stops, and puts into neutral again.

DARRACQ MAKES A LOW-PRICED FOUR

Paris, Nov. 3—The old firm of Darracq & Cie. has brought out its long-expected four-cylinder 14-16-horsepower car, selling at $1,100. One of the most interesting features of the car is its frame, which is stamped from a single sheet of steel, passing under the motor and gear-box. The side channels are of inverted-U section, with flanges along the lower outer edge on which the body rests. The motor has its four cylinders, 3.35 by 3.94 inches, cast *en bloc*. The carbureter consists merely of the float chamber, into an extension of which the jet is screwed; a suction pipe comes down to the top of the jet. The extra air valve chamber and the throttle are cast with the cylinder block.

Roads Building News From All Over The Country

WISCONSIN LAW COMPELS TOWNS TO POST SIGNS

MILWAUKEE, WIS., Nov. 13—The new law requiring town boards in Wisconsin to erect and maintain signs at important crossroads, is being complied with more fully now that the penalty clause has gone into effect. The towns were given until November 1 to erect the signs, but few did so within the limit. No persecutions have been brought, as the town boards pleaded that the farmers have been so busy with crops that they could not get to work on the signs sooner.

James T. Drought, secretary of the Wisconsin State A. A., has dropped his suit for damages against the township of Black Wolf, Winnebago county, under the statute making it a misdemeanor to place bumps and obstructions on the public highway. The town board has removed the obstructions that caused the trouble and promises to be good in the future. Mr. Drought brought the suit simply to test the law and make the boards responsible for the obstructions realize their positions.

The city of Milwaukee has purchased 100,000 gallons of asphaltum oil to be used in sprinkling the streets next summer. All new and resurfaced macadam pavements will be treated first. Twice this amount, however, will be necessary to treat all the streets, and it is expected that a repeat order will be given soon. As one application of the oil, costing the property owners $1 for every 30 feet street front, is expected to last the entire season, the oil will be cheaper than water sprinkling, which costs from 80 cents to $1.50 a season for the same area.

LANCASTER COUNTY, PA., STOPS ROAD IMPROVEMENT

WITMER, PA., Nov. 13—The road supervisors of East Lampeter Township, Lancaster County, Pa., believe that the chief duty of their office is to prevent the roads from being improved, even by an individual at his own expense. So firm are they in this belief that in the December session of court they will apply for an injunction restraining Dr. Donald McCaskey, of Witmer, from improving the roads in the vicinity.

The trouble began last May. Dr. McCaskey, after failing to get the supervisors to fix a dangerous half-mile of yellow clay road, known as the Witmer road, began in despair to make improvements himself. He made a King split-log drag, hired horses from the farmers, and got busy. After fifteen hours of labor, distributed after rains during two months, the neglected part was transformed into a substantial roadway.

The road supervisors began to be censured for their laziness when the neighborhood saw the result of Dr. McCaskey's work, and apparently out of petty spite, obtained an injunction against him. Since then they have been compelled by public opinion to use the split-log drag on fifty miles of dirt roads.

AUTOISTS BOOM GOOD ROADS ADVOCATE FOR GOVERNOR

ALLENTOWN, PA., Nov. 15—At the annual election and banquet of the Lehigh Valley Motor Club held recently, the boom for State Senator W. C. Sproul for next Governor was given a decided boost by J. H. Weeks, president of the Automobile Club of Delaware County, Pa., who incidentally criticised Governor Stuart for his veto of the Philadelphia-Pittsburg highway bill, and assured his hearers that Mr. Sproul, if elected, would accord proper treatment to all good roads legislation.

The following officers were elected to serve during the coming twelvemonth: President, Charles Mosser; vice-president, H. J. Lerch; treasurer, F. H. Sterner; secretary, R. L. Stuart; board of governors, M. H. Strauss, William Erdell and W. D. Schantz.

HOW AUTOISTS HELP KEEP ROADS IN REPAIR

PHILADELPHIA, Nov. 15—Frank Hardart, Sr., is an automobilist 24 hours a day, every day, even though he has large business interests of Philadelphia and other cities. He is also a member of the common council of the Quaker City, but even so he finds time to enter every endurance, reliability, and sociability run held within a hundred miles of his home. He is a prominent official and hard worker in the Quaker City Motor Club, and when he moves to his summer home at Glen Loch he transfers his activities there and wakes up the natives. Recently the East Whiteland Township committee met at his home on the Lancaster pike, when it was shown that $3,400 had been spent during the past year in resurfacing the four miles of that famous old highway that bisects the township. Then the committee censured the authorities of the Borough of Malvern for failure to keep pace with them in keeping "the pike" in good shape in their particular bailiwick, and urged the Malvernites to wake up and realize what they are losing by failing to maintain their roads in good condition. Automobilists of Hardart's caliber are a credit to the cult.

DELAWARE CAPITAL CELEBRATES NEW PAVEMENTS

WILMINGTON, DEL., Nov. 13—Having spent $75,000 in the improvement of streets this year, and having laid the first new pavement in the town, Dover, the capital of the State, is planning a celebration of the event for Thanksgiving, and it is proposed to have as one of the features an automobile parade over the paved streets. Many of the Wilmington autoists will take part.

An arrangement has been made whereby the Delaware Automobile Association is to provide signs to be placed by the Grangers at dangerous road intersections in Brandywine Hundred, and by the city park commissioners on the park drives.

OHIO WITHOUT PROVISION FOR ROAD MAINTENANCE

COLUMBUS, O., Nov. 13—By the decision of the Ohio Supreme Court recently handed down, improved highways in the Buckeye State are left without any provision for their care and maintenance. Conflicting special laws which provided for the care of pikes for a score of years were swept away. The case came up from Gallia County, and simply carries out the opinion of Attorney General Denman, given some time ago. The General Assembly will be called on to enact a law to fill the void.

MARYLAND STATE COMMISSION AND CLUB CONFER

BALTIMORE, Nov. 13—It has been at last arranged for the Maryland Automobile Commission, headed by Governor Crothers, and the Automobile Club of Maryland to get together within the next week and come to some agreement on the automobile bill which the commission wishes to present to the next Assembly. The tax feature is the chief bone of contention, and it is probable that the present law will be changed in this section, as the result of the meeting.

NATIONAL ASSOCIATION MEETS IN SUNFLOWER STATE

TOPEKA, KAN., Nov. 13—The National Good Roads Association will hold its tenth annual session on December 14 and 15 at Topeka. Arrangements for the entertainment of delegates will be made by the Kansas Good Roads Association. The motto proposed for the association is "Work for National and State aid."

RACING ON SPECIAL TRACKS

Automobile racing, as an amusement proposition, has often proved its profitableness. As a popular attraction it ranks with horse racing, bathing beaches, and the Streets of Cairo. In certain events of the past summer it showed ability to take that place in the esteem of the masses which in Roman days was filled by the gladiatorial contests. Naturally its value to the industry fell in proportion to its popularity. The maker learns nothing of the weak points of his car if the car is smashed and the driver killed. The sales manager, too, is likely to find such exhibitions the reverse of good advertising.

Racing on special tracks is devoid of many of the popular—so-called—features, and likewise regains to a considerable degree the engineering value of the races in the early days of the industry. Now the term "special track" appears to require definition. Many people believe that if a defunct horse-track is caught before being cut up into building lots, and is treated with liberal applications of advertising, it becomes *ipso facto* a "motordrome." This idea must be severely discouraged. A special track is a track built specially for automobiles, with due regard to their weight, speed, and destructive effect on the surface.

England has a shining example in the Brooklands track. This big concrete oval is the most valuable asset of the British automobile industry. It provides an amusement which, if it has not so strong a hold on the gladiatorial element, appeals all the more to prospective buyers. At the same time it affords an opportunity for really scientific tests of cars at speed. As an example may be mentioned the experiments on air resistance conducted by the indefatigable S. F. Edge.

The Atlanta track comes the nearest to the value of a Brooklands of anything on this side of the Atlantic. The big racer which Nazzaro drove at 120 miles an hour on Brooklands made but 95 miles an hour on the Atlanta course; and without discussing the merits of Nazzaro and Strang as drivers, it appears that Brooklands has considerably the better of it.

This of course is largely due to the perfect banking of the English course. The degree of banking is figured out by a very simple formula, depending on the speed and the radius of the curve. For a speed of 120 miles an hour, on a thousand-foot radius, the banking should be at an angle of about 44 degrees from horizontal. Brooklands, by providing the right degree of banking, makes the speed reasonably safe for any experienced driver. No other track in the world does so. Moreover, their failure to provide the banking makes it impossible to attain such speeds on them.

On special tracks automobile racing becomes once more a safe and useful sport, beneficial to the industry and still not without profit to the promoters. Atlanta's track has shown great speed, with reasonable safety insured its users; that of Indianapolis, newly surfaced, will live down its disastrous opening; but the highest reward, both financial and otherwise, awaits the man who will give this country a Brooklands.

"FOR MEN OF MODERATE MEANS"

More and more the automobile manufacturers are heeding the demands of that indefinite but powerful class known as "the men of moderate means." By good fortune it happens that what these men want is exactly what is best for the manufacturers, even though some of these latter have not yet recognized the fact. Simplicity and economy are the qualities most desirable in every machine, and the automobile is no exception.

The demands of this class have added to the designer's repertory the block cylinder casting, thermo-syphon cooling, magneto ignition with fixed spark timing, the circulating system of lubrication and the pressed-steel live axle. They have called the designer from the making of road locomotives, and have showed him that greater possibilities and problems even more worthy of the solving lay in the light four, and even in the humble "one-lunger." Any man of moderate skill and some experience can design a fairly satisfactory 40-horsepower car; but the small car calls for original and inventive talent.

To the man of moderate means we must look for much future progress in design. We can already build cars of a speed which must be close to the limits of human endurance; and the reliability of the present automobile compares favorably with that of any other piece of machinery. Were it a question of speed alone, we might well rest on our laurels; but first cost can always be reduced, and running expense and maintenance lightened. These are the directions which future improvement must take; and the industry owes a debt to the men of moderate means for awakening it to this fact.

FRENCH MAKERS NOT ENTHUSIASTIC FOR THE GRAND PRIX

PARIS, Nov. 10—A big query must be placed after the Grand Prix of the Automobile Club of France for the year 1910. The club has announced the race, the conditions are absolute liberty regarding dimensions, horsepower and weight; the distance 500 miles, and the probable date the first week in July. There is a proviso, however, in the nature of the rule that 45 entries must be received by November 30 or no race will be held.

While a fortnight ago it looked as if the 45 could easily be obtained, for the racing board having voted the speed test is comprised of the leaders of all the leading factories, it now appears that the business managers and board of directors do not share the sporting enthusiasm of the Commission Sportive. Thus we have the sight of René de Knyff, chairman of the racing board, being in favor of a speed test, while the Panhard company, of which he is an important unit, shrugs its paternal shoulders in indifference. Louis Renault, as a member of the racing board, votes for a sporting event, but his factory at Billancourt will not produce a speed monster. Brasier rubs his hands and looks wise when a no-limit rule is proposed, but his board of directors shout an emphatic "No." Altogether there are eight French firms, comprising Panhard, Darracq, Charron, Renault, Unic, Peugeot, Motobloc and Dietrich, having come to a common agreement not to race. The foreigners who will abstain are Mercedes and Minerva. Their reasons for refusing to take part in the A. C. F. sporting event are that this year there was no race and business did not suffer, and there is no reason why they should go to the expense of a speed test next season.

The club has made a close enquiry among constructors with the result that it has obtained a promise of 34 cars. No money has been paid, however, and there is always a possibility that some of these will not produce the necessary cash. The willing ones are De Dion-Bouton, one of the few big firms having never previously taken part in a speed test; Mors, Rolland-Pilain, Sizaire-Naudin, Gregoire, Delage and Guillemin; Italy will have Fiat; Germany Benz and probably Opel; Spain Hispano-Suiza; England an Austin team; and either America or England a Mitchell team—for it does not appear to be clear to the club which Mitchell company has made a promise.

The odds are that the race will not be held, but as it only needs 11 more cars to complete the list it is not safe to prophesy. In any case, the race will not have the importance of previous events, for only two leading French firms are entered, the others being voiturette specialists not having made a previous attempt at a big racer.

FURNITURE CITY PLANS ROAD RACE IN 1910

GRAND RAPIDS, MICH., Nov. 13—The automobile club of this city decided at a special meeting to promote an automobile road race next summer, and a committee has been appointed to work out the details. The course chosen is south of the city, about 14 miles in length, and rectangular. It is planned to expend $16,000 in improving this stretch of sandy road and in meeting other expenses.

The committee consists of Albert Stickney, chairman; M. R. Bissell, roads and guards; Benjamin S. Hanchett, funds and privileges; Fred Z. Pantlind, grandstand and parking; W. S. Farrant, officials; A. H. Vandenburg, publicity, and F. C. Warnshuis, entries and prizes. Mr. Stickley, the chairman, into whose hands will fall the general supervision of the event, is one of the leading manufacturers of the city. Mr. Hanchett is general manager of the street railway system. The other members are all prominent in the club's affairs.

ALREADY PLANNING NEXT FAIRMOUNT RACE

PHILADELPHIA, Nov. 15—The Quaker City Motor Club is already at work on the details of the third annual Fairmount Park stock chassis race. It has been practically decided to double the prize money, making the winner's end an even $5,000, with $2,500 for the second car, $1,500 to the third, and $1,000 to the fourth. The success of the race last month was such that no trouble will be experienced in getting the consent of the Fairmount Park Commission to grant again the use of the roads.

The immediate attention of the contest committee, however, is directed to the annual New Year's endurance run, December 29 and 30, which will probably have some Southern city for its objective. Although some of the members are a trifle sore over the rather cavalier treatment the club received from the A. A. A., and some fear that the usual number of entries will not be forthcoming, the pathfinders will start out early next month. Entry blanks will be issued as soon as the route is definitely decided on.

ANNUAL MEETING OF THE A. A. A., NOVEMBER 30

ANNUAL meeting of the board of directors of the American Automobile Association has been called for November 30 at the Hotel Belmont, New York City. At that time the annual reports of the officers and chairman of the various boards will be made, and from the nature of the work accomplished during the past year, these reports are expected to cover a wider field toward illustrating the automobile progress of the country than ever before. The first meeting of tbe new board of directors for the election of officers for the coming year will be held on the following day, December 1.

Strong Western Clubs Join A. A. A.

The Automobile Club of St. Louis, which withdrew from the American Automobile Association about two years ago, has returned to membership in the national organization. The Detroit Motor Club, another of the large and energetic clubs in the West, has applied for membership. Still a third evidence of growth and willingness to co-operate with the association in its efforts for good roads, good laws and favorable touring conditions in all parts of the country, comes from the Pacific Coast, where the latest reports from the California State Association show that the membership has jumped from a few hundred a couple of months ago to over 1,500 at the present time.

Coming on the eve of the annual meeting of the A. A. A. these evidences of increasing growth and membership are particularly encouraging as attesting to the readiness of automobile owners in all parts of the country to work together for the best interests of motoring.

The Automobile Club of St. Louis has a membership of nearly 450. At the recent meeting of its board of directors, when the action to renew its affiliation with the A. A. A. was unanimously adopted, President Samuel D. Capen spoke of the benefits likely to accrue to Missouri in the movement for good roads in view of the fact that the third annual A. A. A. Good Roads Convention will be held at St. Louis next year. President Capen has conferred with President W. W. Cowen, of the Kansas City Automobile Club, toward organizing a strong State association in Missouri. The latter club has nearly 350 members, and other clubs eligible to join are those of Springfield, Joplin and St. Joseph.

NEW AUDITORIUM FOR MILWAUKEE SHOW

MILWAUKEE, WIS., Nov. 13—The Milwaukee Automobile Club has definitely decided to hold the second annual Milwaukee show on February 22 to 27, inclusive, in the new $500,000 Auditorium. The only objection to this date was that it is the same as that of the Kansas City, Mo., show, but it is not thought that the two will conflict seriously. Both were held on the same date last March.

Clarke S. Drake, president of the M. A. C., has been chosen to manage the show. He has already received applications for space. Drawing for reservations will take place January 26. This year, with the advantage of the new location, a definite plan of arrangement can be carried out, giving a separate department for the exhibits of pleasure and commercial cars, motorcycles and accessories. The Auditorium is located at State, Cedar, Fifth and Sixth streets, near what is called Milwaukee's auto-automobile row. In addition to its central location, the Auditorium has the further advantage of being surrounded by wide streets paved with asphalt.

FLAG-TO-FLAG CONTEST POSTPONED

DENVER, Nov. 15—The flag-to-flag endurance and reliability contest for automobiles from Denver to the City of Mexico will be held next Summer instead of this month, as originally planned. The official announcement of the change was made today. It is planned to hold the contest in June or July, during the centennial celebration at the Mexican capital.

NEW YORK UP-STATERS PLAN MARCH SHOW

SYRACUSE, N. Y., Nov. 13—The Automobile Dealers' Association held a meeting at the Yates Hotel last night to discuss the date of the 1910 show. The association would like to have it directly after the Boston show, which opens March 12, but the exact date has not yet been decided. In order to provide ample room for the exhibits that are expected, it is planned to secure the New York State cavalry armory, in addition to that of Company C, which was used last winter. An effort will be made to secure permission to cut a door between the two armories, which adjoin each other, so that visitors will not be obliged to go outdoors to get from one to the other. The members of the various show committees will be named at a future meeting.

COLUMBUS SHOW SPACE ALL ALLOTTED

COLUMBUS, O., Nov. 13—All the space set apart for automobile exhibits in the show to be held under the auspices of the Columbus Automobile Club December 25 to January 1 has been sold. A number of automobile accessories will also be exhibited, and applications for space from accessory makers are numerous. Perin B. Monypeny, Northern Hotel Building, is chairman of the committee in charge of space allotments. It is planned to make one night a society occasion; a special entertainment will be given at the price of a double admission. Sterling Welsh, of Cleveland, is in charge of the decorations, which will be appropriate to the holiday season. About fifty makes of cars will be exhibited.

EXCELLENT COURSE LAID OUT FOR FORT LEE CLIMB

NEW YORK, Nov. 15—A number of New York autoists went over to Fort Lee last Sunday to test the course on which the Edgewater-Fort Lee hill climb is to be held on Thanksgiving Day. The road has been greatly improved, and was found in excellent condition. The Edgewater-Fort Lee Automobile Association, which was formally organized last week, had a committee go over the course with a surveyor to determine the starting and finishing points. Because of sewer construction beyond the crest of the hill, the course had to be cut a little short. Ample space has been left in which to slow down. The start of the climb will be at the gate of Watkins Park, one mile from the finish, and the timing instruments and officials will be located on a bluff overlooking the road. All starts will be standing, as the starting point is on a slight down grade.

The illustrations depict the course being tried out by local trade representatives. The picture on the left is the Velie being driven by E. R. Strobel, of the Garland Auto Company, and the right-hand view shows a Lancia, with Harry Fosdick, of the Hol-Tan Company, at the wheel. The course is easily accessible via the Fort Lee ferry from the foot of Manhattan street (West 130th). New York dealers are well pleased with the course and the attendance possibilities, and their support has assured a representative entry list.

Laying Out the Course for the Climb

What the Clubs Are Doing These Days

GREEN MOUNTAIN CLUB CONFERS ON STATE LAWS

MONTPELIER, VT., Nov. 15—The annual meeting and election of the Automobile Club of Vermont resulted in the choice of the following officers: W. W. Brown, president; James M. Boutwell, first vice-president; Dr. J. Holmes Jackson, second vice-president; S. S. Ballard, secretary and treasurer, and G. H. Morrill, director. The date of the annual meeting was changed from the third Thursday in October to the first Saturday in September.

A vote of thanks was tendered C. W. Gates, the State highway commissioner, for the efficient manner in which he has conducted improvements during the past year. During this time the State received $27,000 in automobile license fees, which is to be expended on the roads. The club voted to continue its campaign for the erection of signs marking both danger points and crossroads. It is expected that the towns will co-operate in the placing of the latter.

Guy W. Bailey, Secretary of State, who became a member at this meeting, addressed the club on the working of the new State law, and expressed the willingness of his department to recommend such modifications as the club might find desirable. James M. Boutwell, J. W. Gordon and J. G. Brown were appointed a committee to confer with Mr. Bailey on this subject. It is the prevailing opinion of the members that the present license fee of $1 for each horsepower is too high. Mr. Bailey said nothing about this tax, but suggested other improvements.

MILWAUKEE CLUB'S SPORT AND BUSINESS

MILWAUKEE, WIS., Nov. 12—The Milwaukee Automobile Club will hold an informal club run on Saturday, November 13, from Milwaukee to Madison, about 80 miles, to see the Wisconsin-Minnesota football game for the Western conference championship. James T. Drought, of the touring board, is an alumnus of Wisconsin, and the club numbers among its members many graduates of both institutions. Parking space has been provided for members.

An imposing committee on legislation has been appointed, consisting of Alonzo Burt, State Senator Julius E. Roehr, Emil O. Hoffman and George A. West, with James T. Drought as chairman. Other committees are those of racing, good roads and runs and tours, presided over by Dr. J. F. Schreiber, Faustin Prinz and M. C. Moore, respectively.

SIGN-BOARDING PLANS IN THE FLOUR CITY

MINNEAPOLIS, MINN., Nov. 13—The Minnesota State Automobile Association is getting a nice profit out of the issue of its annual tour book for the Northwest, and the club officers are working on a plan to divide this profit among the 32 clubs of the association for application to sign-boarding work. Outside of Hennepin County, which boasts of some 200 signs, tbe State is largely destitute of guides to the tourist. Under these conditions it is likely that the plans to state a general movement in this direction will meet with great favor.

HARTFORD CLUB HAS DISTANCE CHART OF TOWNS

HARTFORD, CONN., Nov. 15—William T. Plimpton, assistant secretary of the local club, is working on a chart which, when completed, will show the exact distance between every city in the State of Connecticut. There are sometbing like 275 towns included. The chart should prove of considerable assistance to visiting tourists. Charles D. Rice, chairman of the good roads and sign-boards committee, has presented the club with a large wall map of the State, showing all the main highways.

HARTFORD STILL BOTHERED BY THE TURNPIKE

HARTFORD, CONN., Nov. 13—At the last meeting of the club C. H. Gillette was re-elected a director in the American Automobile Association. F. W. Stickle, Walter S. Schultz, R. D. Britton and S. C. Doty were appointed a grievance committee, and all complaints will in the future be referred to them. The report of the treasurer showed that the organization is in good financial condition. According to figures recently issued by the A. A. A., the Automobile Club of Hartford is eleventh on the list of affiliated organizations in membership. The club has made a considerable gain since the opening of the new quarters. The present membership is 352, and several applications are on file.

Complaints are still being made of excessive speeding on the new Berlin turnpike. The State highway commissioner has threatened to have the stretch patrolled if this is not stopped.

PHILADELPHIANS NEAR THE 1,000 MEMBERSHIP MARK

PHILADELPHIA, Nov. 16—Twenty-eight new members admitted at last week's meeting have brought the membership total of the Automobile Club of Philadelphia up to 980, and a determined effort is being made to reach the thousand mark before tbe December meeting. When that "dead line" is attained the limit allowed by the by-laws will have been reached, and a waiting list be in order.

A recent and highly commendable convenience inaugurated by the club management is the keeping of an up-to-date "chauffeurs' list," on which will be recorded the names of all qualified experts who desire to file their names with the club and are willing to have their records verified. Quite a number of local wheel handlers have already put their names on the list, and the innovation promises to pan out successfully.

NORTH WILDWOOD'S CLUB GETS BACK TO TOWN

PHILADELPHIA, Nov. 16—The North Wildwood Automobile Club, which in the good old wintertime transfers its operations to the Quaker City, will open its social season next Monday night with a "gasoline night" in the Bohemia Hall of the Pen and Pencil Club, at 1026 Walnut Street. Despite the fact that no sanction for the affair has been granted by the A. A. A., the preliminary announcement predicts that in view of the fact that the speed limit has been done away with, many records will be broken. The club is composed largely of Philadelphia automobile tradesmen and news writers.

QUAKER CITY CLUB WILL BANQUET, JANUARY 6

PHILADELPHIA, Nov. 16—Tbe members of the Quaker City Motor Club are evidently in earnest to acquire a clubhouse of their own. Amendments to the by-laws have been introduced providing for an increase in dues, and options have been secured on several sites in the immediate vicinity of Broad and Walnut streets. The committee on annual banquet has selected the evening of Thursday, January 6, for that symposium, when it is expected that prominent local and State officials and well-known national automobile celebrities will be present.

SUNFLOWER STATERS ENJOY SOCIABILITY RUN

MARYSVILLE, KAN., Nov. 13—Despite threatening weather, forty-two of the fifty entries made their appearance for the "sociability run" of the local club, and were not disappointed. The route of the trip, eighty miles in length, lay through the southern half of Marshall county.

MAXWELL-BRISCOE INCREASES PRICES

The Maxwell-Briscoe Motor Company, of Tarrytown, N. Y., has increased the prices of its two small cars, the 12-horsepower and the 22-horsepower; instead of selling at $550 and $850, as heretofore, the prices will now be $600 and $900, respectively. The price of the 30-horsepower model remains the same, $1,500.

The reason for this advance, as stated by the Maxwell company, is the constant increase in the price of raw material. Crude rubber has advanced to such a degree that a set of tires costs to-day from $30 to $60 more than a few years ago. The manufacturer feels this advance even more keenly than the user, because all special prices to manufacturers on quantity orders have been withdrawn or greatly curtailed.

In connection with the advance, the Maxwell company says that among large automobile manufacturers the profit per machine is probably lower than that obtained in making any other class of machinery. For example, in the stationary engine business a 10-horsepower engine selling at $450 gives the manufacturer $100 profit; whereas it is affirmed that the small Maxwell runabout, at the new price of $600, yields but $73 profit.

ANNUAL MEETING OF THE A. S. M. E.

The thirtieth annual meeting of the society will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, December 7 to 10. The social entertainment will be in charge of the members resident in and about New York City, under the immediate direction of a committee of which William D. Hoxie is chairman.

For the afternoon of Wednesday, December 8, an excursion is planned which members and guests will be asked to attend in a body. During the rest of the period there will be opportunities for smaller bodies to visit places of interest. In the evening of the 8th there will be a lecture on agricultural machinery.

The professional papers assigned for the meeting are as follows: "Tests on a Venturi Meter for Boiler Feed," Chas. M. Allen; "The Pitot Tube as a Steam Meter," Geo. F. Gebhardt; "An Electric Gas Meter," C. C. Thomas; "Testing Suction-Gas Producers with a Koerting Ejector," C. M. Garland and A. P. Kratz; "Bituminous Gas Producers," J. R. Bibbins; "Lineshaft Efficiency, Mechanical and Economic," Henry Hess; "Pump Valves and Valve Areas," and a "Report on Cast-Iron Test Bars," A. F. Nagle.

BOOKS FOR THE AUTOMOBILIST

"Automobile Troubles, and How to Remedy Them," by Charles P. Root, is a book for the new driver, repair shark and owners desiring to know what to do in emergencies other than hiring a horse to pull the car home. It is of pocket size, bound in flexible leather covers and consists of two parts. The first, 166 pages in extent, is devoted to troubles and their remedies, starting with a tabular compilation of the more common troubles, which should be very handy. Following that, the rest of the 220 pages is devoted to overhauling the car, such as would be done on putting it away for the winter and general repairs. Not all of the matter is new, but all of it is good. The illustrations are good and illustrate clearly the desired points, but the small number of them used leaves much to be desired in this line. The beginning of the book has the trouble heads arranged alphabetically, but, unfortunately, this arrangement is not carried out through the whole work. It is published by the Charles C. Thompson Company, Chicago.

"The Conquest of the Air"—A. Lawrence Rotch, professor of meteorology at Harvard University, and director of the Blue Hill Meteorological Observatory, writes of aerial navigation from a new point of view. He looks on the air as an ocean of vapor, and similar to the aqueous ocean in its disturbance by tides and currents. The study of these tides and currents has been Professor Rotch's life work, and his knowledge of them has found universal recognition. Such knowledge is invaluable in the direction of free balloons, and of no mean importance to the operators of dirigibles and aeroplanes. The currents of the air move so rapidly in proportion to the speed of the craft which must contend with them that the location of a favorable current is always of great advantage. Until the science of aerodynamics has made far greater progress than the most enthusiastic has yet dared to predict, Professor Rotch's first chapter on "The Ocean of Air" must remain an invaluable guide to aeronauts.

The four remaining chapters of the work, which is modest in size, treat respectively of "The History of Aerostation," "The Dirigible Balloon," "The Flying Machine" and "The Future of Aerial Navigation." They are of particular value as a historical view of the work in this field; no attempt is made to enter into the technical side of aerodynamics. The volume is published by Moffat, Yard & Company, as one of its series of "Present-Day Primers."

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Dec. 25-Jan. 1....Columbus, O., Automobile Show, Columbus Automobile Club.

Dec. 31-Jan. 7....New York City, Grand Central Palace. Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show. New Jersey Exhibition Company.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 19-26......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show. D. H. Lewis, Manager.

FOREIGN

Nov. 12-20........London, Olympia, Eighth Annual International Automobile Show, Society of Motor Manufacturers and Traders.

AMERICAN

Races, Hill Climbs, Etc.

Nov. 19-25........Redlands, Cal., Hill Climb, Mile High Hill Climb Association.

Nov. 20-21........New Orleans. Annual Fall Meet, New Orleans Automobile Club. Homer C. George, Secretary.

Dec. 22-39........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

INDIANAPOLIS IS A BUSY AUTO-MAKING TOWN

INDIANAPOLIS, Nov. 10—Wheeler & Schebler, makers of the Schebler carbureter, are now melting down about two car loads of ingot copper per month, not counting other ingredients as lead, tin and spelter, in the production of carbureters, and not a few shipments are being made in carload lots (approximating 5,000) to individual companies. The plant is in full swing, and ground will soon be broken for a new addition, which will add 59,750 square feet of floor space, of which 8,000 square feet will be in the new foundry. The power plant, using gas engines and producer gas, will have a 250-horsepower engine in the new acquisition.

The Diamond Chain Company, besides the regular line of sprocket chains as used in automobile work, is handling a wide line of chains, and, contrary to the usual expectation, chain work is increasing with such rapid strides that the company is hard pressed in the matter of handling all the trade it is offered. New additions of machinery are being made as rapidly as possible, and many improvements are being added. A new garage has been built for the officers of the company, and the electrical equipment of the plant includes a complete charging equipment of the latest and best design to handle electric vehicles.

D. M. Parry, of the Parry Auto Company, is banking on the permanence of the automobile, and among other interests is making every preparation to manufacture cars on a large basis. The Parry cars, of which there are two models (roadster and touring car), are being pushed out with the idea that the serial number 5,000 will show up on the production dial before the end of the 1909-'10 period. Besides the large plant now available, the company is adding much more floor space by way of new buildings.

Nordyke & Marmon, in their well equipped plant, are making their own cylinders, aluminum castings, brass, bronze and in fine everything of moment. The new models are well in hand; cars are being put out at a rapid rate, and the quality of the work being done is up to the well-known standard of the company. The engineering office is practically through with 1910 designing, and the able "staff" is now in a position to carefully check up on every detail of the work as it comes through.

Charles Blizzard, general manager, and Bruce Ford, engineer, of the Electric Storage Battery Company, Philadelphia, reached Indianapolis, having done Chicago, a few days ago. It is the settled policy of the company to look well after the users of Exide batteries, and the management seems to understand the value of personal calls on the trade.

F. W. Spracke Machine Company, parts maker, is doing a vast amount of work for automobile makers throughout the country, and when the representative of THE AUTOMOBILE called he was entertained in a most interesting way, having had the pleasure of seeing more kinds of grinders doing accurate work than is usually found under one roof. F. W. Spracke, himself a tool designer of wide reputation, recently perfected a grinder which will grind (all over) such irregular shapes as cams for integral camshafts, thus saving much time and doing the work far more accurately than seems to be possible in any other way.

George Schebler, of Wheeler & Schebler, recently completed a twelve-cylinder motor, and having placed it in a chassis of suitable design, started on a jaunt overland. The motor, which is of the water-cooled V type, performs extremely well, and the compactness of the power plant is one of the wonders of Indianapolis.

The Indianapolis Speedway is now being brick-paved, and the entire undertaking will be completed in about three weeks. The banking is scientifically done and the tangents are as level as any road can be. The representative of the AUTOMOBILE was unable to discover a spot over the surface that falls outside of the specifications of 3-8-inch depression in twelve feet. The paving brick used are of a superior grade, and the grouting is done with the utmost care. A 15-foot sweep to the sides of the paved way is being prepared so that if a car does run wild it will have ample room to play in.

TWELVE AUTO MAKERS IN INDIANAPOLIS

INDIANAPOLIS, IND., Nov. 15—Apparently the only limit to building automobiles in this city next season will be the ability to get sufficient parts. Present estimates base next year's production of local factories at 25,000 cars.

Another new company has just been added to the list, making twelve concerns in the city now making automobiles. The new company is the Star Motor Car Company, which has an authorized capitalization of $100,000, of which $75,000 is paid in. A plant will be built at once and a line of runabouts and touring cars to sell at about $1,000 will be made, together with delivery wagons and trucks.

In addition to this, there will be three other practically new local companies in the field during the 1910 season. These are the Cole Motor Car Company, organized from the motor buggy business of the Cole Carriage Company; the Parry Automobile Company, which will build 5,000 cars, and the Empire Motor Car Company.

TIRETOWN NEWS TELLS OF BIG GOODYEAR CONTRACT

AKRON, O., Nov. 14—The Goodyear Tire & Rubber Company has applied to the city council for the vacation of a part of an East Akron street for the purpose, if the request is granted, of adding to its plant two factory buildings, five stories high, aggregating 500 feet in length and affording 150,000 square feet of floor space; the establishment of a reclaiming plant with a capacity of ten tons a day; and the employment of 600 to 800 additional men inside of 90 days. The closing of contracts by the company to furnish automobile tires for Buick, Cadillac, Welch, Oldsmobile, Oakland, Reliance, and Rapid, the concerns constituting the General Motors Company, has necessitated a large increase in the capacity of the plant, and the company is compelled to enlarge or go elsewhere.

Though a story has been current that the Goodyear Company was about to be absorbed by the General Motors Company, President F. A. Seiberling positively denies any such intention. It is well understood, however, that the offer to move the plant to Detroit traces back to the big contract for tires with the General Motors Company, but the Goodyear officers refuse to discuss this phase of the situation.

The Palmer-Hawkins Company of this city has equipped a motor truck with a set of its sectional tires 36" x 10", claimed to be the largest set of solid rubber tires ever manufactured or applied in the United States, if not in the world. The truck will be used in Florida, where the sandy roads render the use of ordinary tires impossible.

The Motz Clincher Tire & Rubber Company began an action in the Federal Court at Cleveland, November 13, against the Swinehart Clincher Tire & Rubber Company, alleging infringement of a patent covering its twin-tread and webbed-side tire, which it claims is also manufactured by the Swinehart Company. An injunction and damages are asked. A number of similar suits against the same company will follow, the Motz company says.

Chalmers-Detroit Ambulance for Nassau Hospital

This ambulance, which was built by Carl H. Page & Company, New York representatives of the Chalmers-Detroit Motor Company, for the Nassau Hospital, is reputed to be one of the finest specimens of its type in the metropolitan district. The body is mounted on a "Forty" chassis, and is fitted with every convenience for the patient that the medical fraternity could suggest.

FRENCH TYPE RUNABOUT FROM LONG ISLAND

Single-cylinder runabouts of the type familiarized by the French voiturette races are to be built in this country by a recently organized concern known as The Only Car Company, Inc., located at Port Jefferson, L. I. The company is capitalized at $300,000. At present work on sample cars is being pushed in temporary quarters, but a concrete building having 16,000 square feet of floor space has been planned and will be erected soon.

The single-cylinder motor is to be of the long-stroke type, resembling the Sizaire-Naudin, Lion-Peugeot and other French types. The racing cars of these companies develop 20 horsepower from a single-cylinder motor of 4 inches bore. The cars at present under construction are of the roadster type, and will be entered in races in the spring. They will sell at $700, with a guaranteed speed of 60 miles an hour. Long wheelbase, a large hood, straight-line shaft drive, imported ball bearings, and liberally designed steering knuckles and gear are some of the features mentioned.

The chief engineer of the company is François Richard, who will be remembered as the designer and builder for A. G. Vanderbilt of an eight-cylinder car which was intended to compete in one of the meets at Ormond Beach several years ago.

Plans for the future include the production, in addition to the roadster type, of a five-passenger model, together with taxicabs and light delivery wagons. The simplicity and economy of the modern single-cylinder engine should open a wide field for cars of this type, and although popular prejudice must be overcome, they should find extensive use.

1910 JACKSON "MUD HEN" ON ITS 1909 RUN

Starting November 16 from Jackson, Mich., with a letter from the mayor of that city to the mayor of Bangor, Me., E. P. Blake, of Boston, and Charles G. Percival, of New York, accompanied by a mechanic, will attempt to lower the 1,600-mile non-stop record which they made one year ago in the snow, rain and mud, thereby earning for themselves and the car the name of the Jackson "Mud Hen." This year's trip will be three weeks later in the season, and the "Mud Hen" expects to encounter even worse weather than a year ago, when the drive was day and night to Bangor without stopping the engine once. The only stops again this time will be for the purpose of taking on oil and gasoline, and for food. A relay of newspaper representatives will accompany the car for the purpose of checking, and the route will take in Detroit, Toledo, Cleveland, Buffalo, Rochester, Albany, Springfield, Boston, Portland and Bangor. The car, which is a 40-horsepower Jackson, has for its ignition a U. & H. magneto and is equipped with Goodyear tires.

WHAT IS GOING ON AT SOUTH BEND

South Bend, Ind., Nov. 15—The Studebaker Automobile Company, which has been doing quite a large business in electric vehicles, has decided that it will go into this branch of the work on a larger scale, and with that in mind has separated the electric from the other parts of the work and placed C. H. Tyler, formerly connected with the Chicago branch, in charge. The new idea is to take advantage of the experience gained, build cars in accordance with the dictates of this experience and place the whole matter on an independent footing, holding a department head responsible for the result. Mr. Tyler has taken hold of the work and is making every effort count in the production of electric vehicles. The headquarters of the company has been transfered from Cleveland, Ohio, to this city. Hayden Eames is in charge as general manager.

The addition which is being erected to the plant of the Simplex Motor Car Company, of Mishawaka, is nearing completion. The company is now turning out a car a day. The company has just finished three seven-passenger touring cars, which were shipped to Los Angeles.

Teagarden & Putt, of Goshen, have enlarged their salesroom and garage by the leasing of the first floor in the Kohler Block on North Main Street. They intend to add an electric charging plant and be able in a short time to do all kinds of repairing.

N. L. Otis, of this city, has just been appointed agent here for the Reo and the Rauch & Lang electric.

Charles G. Doriot, of Colombia City, has been appointed representative in that city for the Buick and Oakland, and expects to install a garage and salesroom in a short time.

The Oswald Motor Company, of Goshen, has increased its capital stock. The company recently took over the building which it now occupies, and is doing a thriving business.

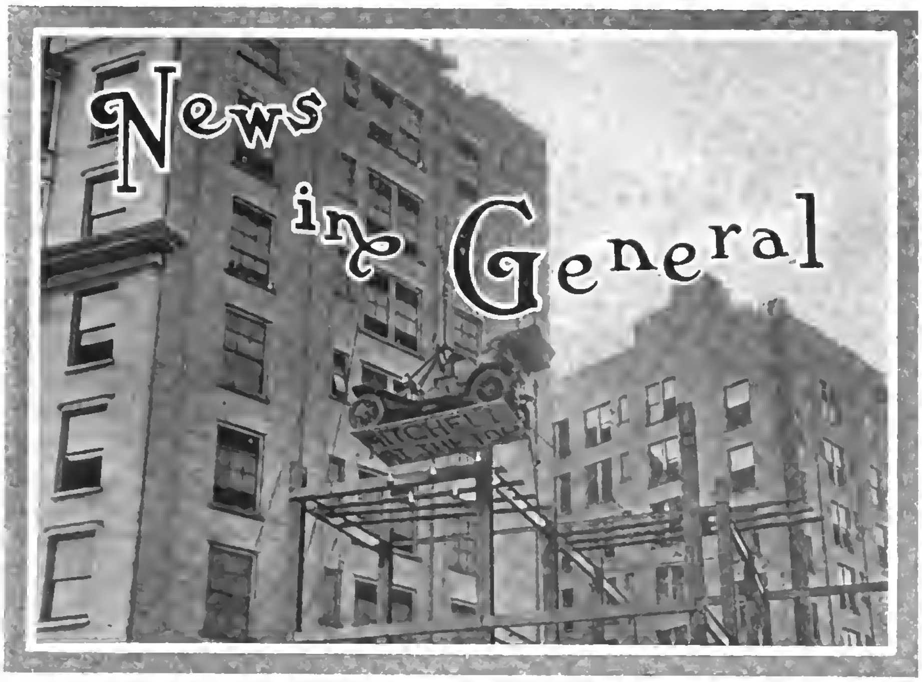
"CARBURETER" SCHEBLER'S 12-CYLINDER

Indianapolis, Ind., Nov. 15—After several months of experimenting, George Schebler, of the Wheeler-Schebler Company, has completed an automobile equipped with a twelve-cylinder motor. The cylinders are cast singly and are 3 1-2 by 4 inches. They are arranged at an angle of thirty degrees, six on a side. By an original coupling arrangement, six of the cylinders can be cut out or cut in without changing gears. The chassis is of the Marion type, with the exception of the motor.

Mr. Schebler has driven the car about 200 miles with satisfactory results. It is said to be especially powerful for hill climbing, but its speed has not been thoroughly tested. It is of about 75-horsepower. Mr. Schebler built the car merely to try out some ideas he has fostered for some time.

President Frank Briscoe in His Latest Brush Runabout

The well-known president of the Brush Runabout Company, of Detroit, is an expert at the wheel, and the photograph shows him trying out one of the little roadsters the company is producing for the 1910 market.



Mitchell, Official Pacemaker, Climbs an Atlanta Sky Scraper

Arriving in Atlanta ahead of the reliability run that blazed the national highway from New York City to the Gate City of the South, the Mitchell pacemaker, at the instance of its enterprising Southern representative, Robert C. Howard, was raised to the top of a building undergoing construction, and swung over Peachtree street, where during the Atlanta automobile show it was illuminated at night by a cluster of electric lights. The novel exhibit attracted the attention of thousands.

Lloyds Wouldn't Insure Pierce—It is the general impression that the organization of insurance men who are known both in New York and London as Lloyds will issue insurance of any kind. The New York Lloyds has been known to insure promoters against loss by rain on days set for outdoor contests, and everyone knows of the election insurances which they frequently make. The Pierce-Arrow Company now says that before the Glidden Tour this year it wrote to both the New York and London Lloyds asking if they would insure the Pierce-Arrows against losing the trophy. Two policies were proposed, one covering the winning of the trophies by Pierce-Arrow cars and the other that at least one of the four cars of that make entered would get a perfect score. Both the New York and London Lloyds decided it was a matter they did not care to handle.

Big Rapid Factory Additions—These are strenuous days around the big plant of the Rapid Motor Vehicle Company, at Pontiac, Mich. Large additions are in progress of erection, and an army of workmen are working day and night. The new buildings under construction are all of the Kahn system of reinforced concrete and will be modern in equipment in every detail. The additions to the plant consist of one building 640x60 feet, three stories high; two buildings 300x100 feet, each three stories high, and a power house 119x120 feet. With the completion of these new structures the factories of the Rapid will cover an area of 16 acres.

Liggett Buys Hatcher Company—The factory and plant of the Hatcher Auto-Parts Company, of Cleveland, has been purchased by the Liggett Spring & Axle Company, of Pittsburg. The specialties which have been manufactured by the Hatcher people will be continued at the Cleveland plant, and Wm. A. Cluff, who has been manager of the Hatcher works for the past five years, will remain in charge. In addition the Liggett Company will continue to turn out from its works at Monongahela, Pa., all types of high-grade automobile springs and axles. The company is also making roller bearings of an improved type.

Supplementary Spring Suit—The St. Louis Supplementary Spiral Spring Company, of St. Louis, has filed suit in the New York Circuit Court against the Supplementary Spiral Spring Company, 1876 Broadway, New York, for infringement of the Furmidge patent, No. 807,612, which the St. Louis company holds. The St. Louis company quotes in its favor the judgment rendered by the Patent Office October 30, 1909, on the interference between the application dated December 19, 1907, of J. H. Graham of the New York company, and the Furmidge patent.

New Power House for Kissel—The Kissel Motor Car Company, of Hartford, Wis., will on December 1 occupy its new power house, built to replace the structure destroyed by fire early in September. The equipment includes a 400-500-horsepower tandem compound condenser engine, with one 160-kw. and one 165-kw. direct-current generator. All machines and tools will be operated by individual motors. The power house is 44 x 30 feet in size and of reinforced concrete and brick construction.

Mutual Benefit Prospering—The Mutual Benefit Association of the Pope Mfg. Co., Hartford, Conn., recently elected W. J. Murray president, R. B. Wright vice-president, A. G. Hedstrom secretary and H. S. Seymour treasurer. R. B. Wright, J. H. Cudworth and P. Foley were elected auditors. Reports showed that the association has a membership in excess of three hundred and a balance of $1,594.75 in the treasury. During the past year the association paid out $769 in sick benefits to members.

What Would Have Happened if the motor of Count de Lambert's aeroplane had stopped when he made his remarkable flight from Juvisy to Paris and around the Eiffel Tower? Answer: He would have glided to the ground with perfect ease. Lavalette & Company asks the question, but seems to have overlooked the answer. That oversight, however, does not lessen the importance of the reliable ignition furnished Count de Lambert on his flight by the Eisemann magneto.

Rambler Output Is Conservative—In giving an estimate of their probable output for 1910, Thomas B. Jeffery & Company, Kenosha, Wis., makers of the Rambler, announce that they will build only 2,500 cars, a figure likely to cause some astonishment to those who are aware of the immensity of the Jeffery plant. The conservatism of the company's plans as far as quantity is concerned is officially stated, however, and the above number will represent the actual output.

Franklin Lumber Yards—To assure a supply of properly seasoned wood for the manufacture of the laminated wood chassis frames of the Franklin cars, the H. H. Franklin Mfg. Co. keeps in stock about 150 miles of lumber, some of which is kept as long as two years. A recent inventory showed 701,626 feet, sufficient for two years' consumption. The wood used is white ash, which comes from several districts in New York State and Pennsylvania.

Japanese Buys Baker Electric—During the recent visit of the Japanese Industrial Commission to Cleveland, the Hon. Sakutaro Satake, M. P., president of the Tokio Electric Light Company, inspected the plant of the Baker Motor Vehicle Company and finally placed an order for a Baker victoria for his personal use in Tokio. The car will be taken to Japan on the "Chiyo Maru," on which the commissioners will sail.

Some of Grabowsky's Orders—About a year ago the Acme White Lead and Color Works, of Detroit, Mich., purchased a Grabowsky truck, which was found so satisfactory that it recently ordered another. The Stroh Brewery Company, of the same city, after using a Grabowsky for a few months, also obtained such good results that it purchased another.

Learning to Fly Aeroplanes—The Curtiss aeroplane belonging to A. P. Warner, of the Warner Instrument Company, has been at Beloit several days for practice flights. This is the machine that was on exhibition at Madison Square Garden, New York City, and at St. Louis recently. Mr. Warner has made several short flights and has attained a height of about 50 feet.

IN AND ABOUT THE AGENCIES

Palmer-Singer Agencies—Fred J. Titus, assistant sales manager of the Palmer & Singer Mfg. Co., is touring New England and New York in a 1910 Palmer-Singer 6-60, laying out agencies en route. The following have been established: The Holcomb Company, New Haven, Conn.; Mr. Livingston, of Hotchkiss & Livingston, Waterbury, Conn.; Andrews & Coleman, Providence, R. I., and Herbert Dike, Boston. Before starting a contract was made with Terry Brothers, of Glenridge, N. J., who will open a salesroom in Newark. Mr. Titus is on his way to Buffalo, N. Y., and will return by way of Binghamton.

American Truck and Hart-Kraft, Birmingham, Ala.—The Commercial Motor Truck Company, 738 Brown-Marx Building, has taken the agencies for the American truck and the Hart-Kraft delivery wagons for this district, handling commercial cars exclusively.

Oldsmobile and Oakland, Houston, Tex.—On November 1 the Houston Motor Car Company took over the representation for the Oldsmobile and Oakland. The Olds-Oakland Company will devote itself to the wholesale end of the business.

Great Western, Detroit—The Great Western Automobile Company, of Peru, Ind., opened a sales agency November 15 at 878 Woodward avenue, Detroit, under the name of the Great Western Automobile Company of Detroit.

Thomas, Lynn, Mass.—The E. R. Thomas Motor-Branch Company, of Boston, which distributes Thomas cars in New England, has contracted with C. E. Whitten to handle the cars in Lynn.

Parry, St. Louis—The Petrie-Phillips Automobile Company, which has been appointed local agent for the Parry Automobile Company, of Indianaoplis, has opened a salesroom at 1127 Olive street.

Overland, Brooklyn, N. Y.—C. I. Silver has been appointed agent for the Overland and until his new building is completed will be at 71 Flatbush avenue.

Continental Tires, Portland, Ore.—The Continental Caoutchouc Company announces that it has appointed the Goodyear Rubber Company agent for Continental tires and rims in that district.

Palmer-Singer, Newark, N. J.—R. M. Terry, Palmer-Singer agent in Newark, has taken a long lease on 38 William street, at the corner of Halsey, where he is occupying a large fireproof building.

Overland, Atlanta, Ga.—The Overland Southern Automobile Company has moved into its new quarters in the Peachtree Auditorium Garage, where it has accommodations for 150 cars.

Apperson, Atlanta, Ga.—Alfred Austell has been appointed Apperson agent in this city and will open a garage and salesroom on Auburn avenue shortly.

Ford, Portland, Ore.—The Standard Motor Car Company, of 86 Tenth street, has been organized here to look after the interests of the Ford car.

Isotta, Los Angeles, Cal.—The Motor Car Import Company has been organized to take the Southern California agency for the Isotta cars.

PERSONAL TRADE MENTION

John Gillespie, who has just been elected secretary of the Detroit Motor Club, will be remembered by participants in the Glidden Tour last summer as the secretary of the Detroit Automobile Dealers' Association. He was largely responsible for the excellent arrangements provided in Detroit for the reception of the visitors and the successful start of the tour.

Will Soules, the well-known driver, who formerly piloted Pope-Toledo racers, is now in charge of the testing department of the Croxton-Keeton Motor Company, at Massillon, O.

Charles Waterman, formerly with the Maxwell-Briscoe Company at New Castle, Ind., has been appointed superintendent of the Southern Motor Works, at Jackson, Tenn.

FRAYER-MILLER DEVELOPMENTS

Columbus, O., Nov. 13—Columbus stockholders in the Oscar Lear Automobile Company, of Springfield, O., have received word that E. S. Kelly, of Springfield, has purchased a controlling interest in the concern and will reorganize it with a capital of $500,000. Recently the General Motors Company bought the holdings of William Miller, of Columbus. Mr. Kelly purchased this block and also that of Oscar Lear, giving him control. Charles L. Bauer, at present receiver of the company, will be made general manager after the reorganization. The company now manufactures commercial vehicles exclusively.

OBITUARY

George William Hoffman, the well-known manufacturer of U. S. Metal Polish and other specialties, died at his home in Indianapolis on Friday, October 22, after a brief illness. The business will henceforth be managed by his widow, Mrs. Hoffman, without change in policy.

RECENT TRADE PUBLICATIONS

The Metz Company, Waltham, Mass.—This company has adopted the policy of selling all the necessary component parts of an automobile, with full instructions, thereby allowing the buyer to save the expense of having them assembled at the factory. Also the buyer acquires a knowledge of his car, by assembling it himself, that is likely to prove of material aid to him. The Metz catalog consists of eleven loose sheets in an artistic cover, describing the car and explaining the Metz idea of construction. Men of any mechanical talent will find much in it to interest them, and even those of no pretensions in this line may take heart on the reading of it.

The Electric Storage Battery Company, Philadelphia—This pamphlet hardly comes under the head of a catalog, as it makes no claims for the "Exide" batteries manufactured by the company which brings it out. Rather it should rate as a book of instruction on the care of storage batteries of whatever kind. The text is from a paper read by H. M. Beck, an engineer of the Electric Storage Battery Company, at the meeting of the Society of Automobile Engineers, August, 1909. The principles of the chemical and electrical action in a storage battery, and the use, care and troubles of such batteries are concisely set forth in the compass of seven closely printed pages.

DeHymel, in Stoddard-Dayton, Winning Five-Mile Texas State Championship

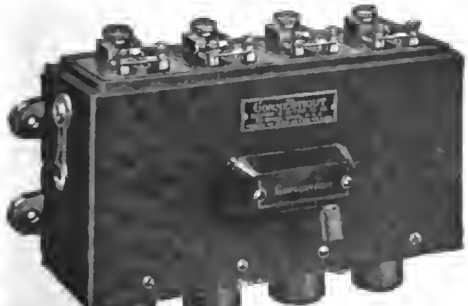
At the recent Texas State Fair, at Dallas, the Stoddard-Dayton, entered by the Alamo Auto Company, of that city, and driven by DeHymel, scored a notable victory in the five-mile State championship, beating out two noted competitors. The car also established a new State record for the track mile of :51 3-5.

Information for Auto Users

New Connecticut Coils—The Connecticut Telephone & Electric Company, of Meriden, Conn., has brought out for 1910 an entirely new model of spark coil with master vibrator, a departure from its previous practice. With the ordinary type of coil, each unit of which has its own vibrator, it is necessary to adjust

CONNECTICUT MASTER VIBRATOR COIL

each separately—an operation which takes no mean degree of skill, if creditable results are to be obtained. Take for example a four-cylinder engine with this type of coil. The vibrator of No. 1 cylinder may be adjusted to draw one-half ampere, firing that cylinder exactly on dead center; No. 2 coil may be taking one ampere, with the result that its cylinder is firing two or three degrees past center; No. 3 may be taking two or three amperes, and firing five or ten degrees beyond the center; No. 4 may be taking one-quarter ampere, and firing before center. Naturally the performance of the engine is poor.



CONNECTICUT SPARK COIL, TYPE X

This state of affairs is impossible in the master-vibrator type, as the single vibrator acts for all the coils. Each coil unit must draw exactly the same amount of current, and fire its cylinder at exactly the same point. It is said that the difference in the running of the engine can often be detected by the ear.

The Connecticut master-vibrator coil is made on the unit-coil principle, licensed by the Unit Coil Company, and each coil has a cut-out button for testing purposes. Each unit also has a patented shield which prevents induction between coils.

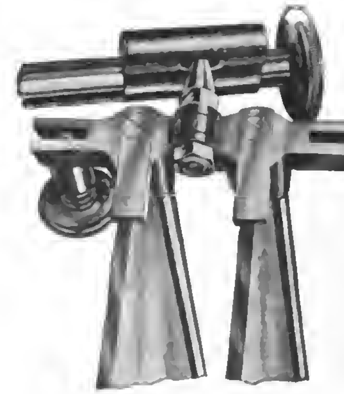
Another new Connecticut model is the "Type X," of the ordinary design, intended to fill the demand for a less expensive coil than the regular Connecticut makes. It is considerably smaller than the standard coil, though built on the unit system, and sells at a very reasonable price.

1910 Banker Wind Shields—Four different styles of shields will be made by the Banker Wind Shield Company, of Pittsburg, during the coming season, and these will present no radical changes. They will be known as types 1, 2, 4 and 5. Type 1 is a single glass, fitted into a 3-8-inch channel in a 7-8-inch 16-gauge brass tube frame. No. 2 is of the divided

BANKER DOUBLE-FOLD SHIELD, NO. 2

folding variety. The proportions are such that when the upper half is folded down the entire shield is below the driver's line of vision. When not in use the entire shield folds down forward over the hood.

No. 4 is made in response to the demand for a low-priced shield. Workmanship and material are of the same grade as in the others, but the construction is simplified by attaching the lower



HINGE USED ON 1910 BANKER WIND SHIELDS

half rigidly to the dash, only the upper half being hinged. By doing away with the side arms and brackets and the telescoping rods the price is reduced.

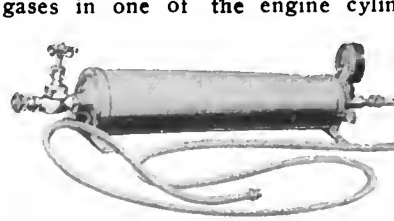
No. 5 shield is made expressly for racing-type runabouts, in which the front seat is set further back from the dash than usual. In such cases the ordinary design of shield is often practically useless. No. 5 has its lower half attached to the dash at an angle of 60 degrees, bringing the upper half back into a useful position.

"All-in-One" Spark Plug—This plug has all the features of the usual plug, with the addition of a compression-relief and priming cup. With the approach of cold weather the latter becomes especially valuable, for many engines which start with difficulty in cold weather may be aroused by pouring a few drops of gasoline directly into the cylinder. The "All-in-One" spark plug provides the priming cup, when one is not regularly fitted to each cylinder; and the cup in connection with the spark plug has the additional merit that the gasoline is introduced into the most favorable place, and nearest to the spark. The maker, the Comet Electrical Mfg. Co., claims that by first priming the cylinders, any engine will start on a single turn of the crank in almost arctic temperatures.

"ALL-IN-ONE" SPARK PLUG

The combination of spark plug and compression-relief provides an easy method of cleaning the plug without removing it. The relief opening communicates with the space around the insulation of the plug, so that if the cocks are opened while the engine is running all soot and dirt is blown off the plug. These plugs are sold only by mail.

H. & C. Tire Inflator—"Let the engine do the work," says the H. & C. Tire Inflator Company, of Dayton, O. The device made by this company is intended to provide a simple means whereby tires may be inflated by utilizing the burnt gases in one of the engine cylinders.



H. & C. TIRE INFLATOR

These gases, for the most part carbon dioxide and nitrogen, are not injurious to rubber. The device consists mainly of a suitable filter, which cools off the gas and prevents oil and other unsuitable substances from entering the tire. As the gases are delivered cool, the tire need only be inflated by the desired pressure, as shown by the indicator, there being no cooling off and consequent reduction of pressure after completion.

The filter has a body formed from a piece of brass tubing 2⅝ by 10½ inches, with brass cap ends; it carries the pressure gauge and shut-off valve. A check valve, to be screwed into one cylinder in place of the compression cock, is connected to this filter by copper tubing.

INDEX TO ADVERTISERS

VOL. XXI · NEW YORK—THURSDAY, NOVEMBER 25, 1909—CHICAGO · NO. 22

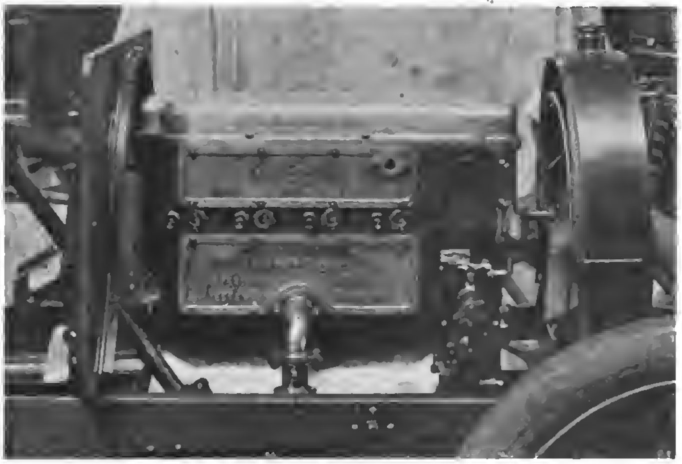
THE AUTOMOBILE

LONDON HOLDS EUROPE'S AUTO SHOW

By Basil Weston

LONDON, Nov. 15—All roads now lead to Olympia—as far as European automobilists are concerned—for this mammoth building opened its doors Saturday to disclose the only big automobile exhibition which is to be held in Europe this Winter. And a tour of inspection shows that the display at Olympia does ample justice to the occasion, for, both as regards extent and variety, the exhibits surpass anything that has been witnessed on this side before. Certainly the artistic surroundings of the Paris Salon are conspicuous by their absence, but, then, the British buyer pays but little attention to mere meretricious display, and prefers to concentrate his thoughts on the exhibits themselves, so that the businesslike appearance of the interior of the building is easily and satisfactorily explained.

So great was the demand for space, when it became definitely known that there would be no shows in Paris and Berlin, that the promoters—the Society of Motor Manufacturers and Traders—caused extensive alterations to be made, so that the added space has enabled a total of over 300 firms to find room for their stands. Even this was not sufficient, for over twenty car manu-



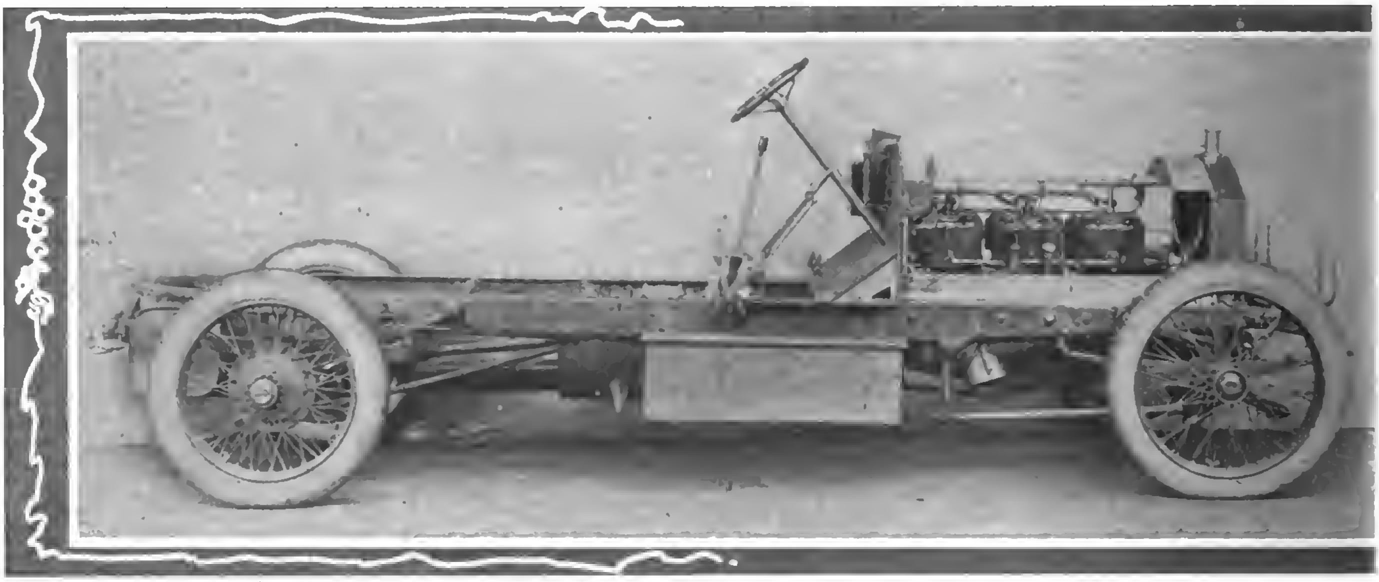
Bentall & Company's New Silent Piston Valve Engine

facturing firms have been unable to secure space. Among these unfortunates must be numbered the agents of the Mercedes, who, owing to reconstruction of their company, were not in a position to put in an application till too late. Other than Mercedes no firm of any standing is unrepresented, and hence it may be rightly stated that a more complete exhibition than Olympia would be quite an impossibility.

Opening Marked by Readiness of Exhibitors—A sign which augured well for the success of the show was the fact that at 10 o'clock Saturday morning, when the doors were opened without any official ceremony, every car was staged in position so that the salesmen and attendants were not unprepared when the flood of visitors poured in. Such a crowd on the opening day has not been recorded at any previous exhibition, and from the number of orders and promising inquiries that have already been in evidence, all the leading exhibitors are beginning to conjure up visions of a thoroughly good year's business. A remarkable feature, too, is the number of foreigners that are at the show. French, German, Belgian and Italian motorists are everywhere to be seen, volubly discussing the various features of note, and obviously impressed with the extent and quality of the British exhibits.

There is a curious absence of what might be called artificial attractions—such as racing cars or vehicles of historical interest—artificial because such productions bear little, if any, relation to the ordinary productions of the exhibiting firms and are obviously staged merely to attract the crowd. Not a racing car is to be found, while of the second category mentioned above, the sole example is the Arrol-Johnston car which accompanied Lieutenant—now Sir—Ernest Shackleton on his recent South Polar expedition. Instead, all the cars are honest examples of the firms' productions and are staged as such.

A detailed inspection of the cars reveals many tendencies of design—many features of interest—which previously may have been used on one or two cars, but which are now becoming general practice. It may be of interest to have these features noted down before the individual cars are dealt with.



45-Horsepower Napier Exhibited at Olympia Show—Note Governor Opposite Cylinder No. 4, and Rear Spring Attachment

Lower Powers Now the Thing—In the first place there is a marked decrease in the average power of the cars. The high efficiency of the present-day engine and transmission enables the car of medium power to set up standards of performance which, a few years ago, could not have been surpassed by the biggest touring car made.

Both this fact, and also the general increase in taxation, in this country and in France and Germany, have made manufacturers turn their attention to the small car as something for which there is a growing demand from all classes, and the result is the 15-horsepower model which is to be found everywhere—Napier, Daimler, Fiat Itala, Austin (Mercedes also, though not exhibited), and a host of others. There are the other cars, of course, of lower and higher powers, but this 15-horsepower model is evidently considered to be a type for which there will be a very large sale. The average 15-horsepower engine has a bore and stroke of 80 x 120 mm, though the stroke might even average more than this amount. The cylinder dimensions constitute the only point of agreement, for the methods of construction differ in every imaginable way. The cylinders are cast in

singles, pairs and fours, with perhaps a balance in favor of this last type.

Some of the castings, which frequently include the top half of the crankcase, are truly wonderful examples of the molder's art. The inlet and exhaust passages (the latter being equipped with radiating fins) are included in the castings, and the resultant simplicity is such that, until a close inspection has been made, one inclines to the belief that some parts have been intentionally omitted.

Many Unit Power Plants Seen—This construction makes a very neat engine, and the pleasing effect is increased when, as is the case with half a dozen cars of this type, the crankcase is connected by side arms to the gearbox casting, so that the engine and gearbox are combined to form a single unit. The Star, Imperia and Napier 15-horsepower cars are built on this plan, while the last named has its flywheel at the front of the engine, with the result that the connecting arms need not be cranked outward.

The rate of increase in the number of six-cylinder cars has not been maintained, and it would be difficult to mention any new firm which has taken up this type. Many of the leading makers show a high-powered car with six-cylinder engine, as usual, while the only concern which confines its attention solely to this type is Rolls-Royce, whose 40-50-horsepower car, of long-distance trial fame, is staged almost without alteration. Six-cylinder engines are usually found with cylinders in pairs, though Rolls-Royce and Delaunay-Belleville have two sets of three cylinders and the Wolseley has a single casting for the six cylinders. In the case of this last, the water jacket is made of sheet steel screwed to the casting in the same way as employed on this firm's successful aero engines. The new eight-cylinder 35-horsepower De Dion is staged, but this is, of course, alone in its class.

More Bearings on Crankshafts—Regarding the further engine features (dealing with all types) there is a tendency to provide the crankshaft with the full number of bearings whenever possible—five bearings in the case of the four-cylinder engine, instead of the three frequently used in previous years. Ball bearings have disappeared from the crankshaft except in the case of the smallest fours, which in this case have but two bearings for the four-throw crankshaft. Both these changes are doubtless caused by the fact that the present-day engine parts have to withstand much more shock and hard work than ever before on account of the lighter construction and the higher compression employed—85 to 90 pounds being the pressure for some of the medium-sized engines.

When the subject of valves is mentioned, sufficient matter is at hand to fill pages. The success of the Knight sliding-sleeve engine (which is only shown on the Daimler and Minerva stands, for the Panhard company have not yet completed their first cars with this engine) has turned the efforts of all designers in this direction, and it is an open secret that the majority of the well-known firms have been experimenting with sliding valves during the past year. Apparently their efforts have not been rewarded with success, for but two new engines have appeared—the Hewitt and the Benthall—both with piston valves working in cylinders communicating with the main combustion chamber. These engines will be described later. There are several examples of two-cycle engines, but this type does not yet become popular, though it is by no means unlikely that the next show will reveal a big advance in this construction.

Larger Valve Sizes Noticeable—The poppet valves of the usual type have been considerably increased in size so that in many cases the valves have now to be placed on opposite sides of the cylinder. The provision of a cover plate in front of the valve stems finds much favor.

Accessibility is a matter which has clearly been kept prominently in the mind of the designer—not only with regard to the engine, but also the other parts of the car. Quite the standard practice now is to fit a cross-shaft at the front of the engine, driving the pump at the one end and the magneto at the other. Usually this shaft is operated by spiral gears so that the noise set up by the latter after continued use may be obviated. Both pumps and magneto are easily detachable.

Lubrication is a matter that has received the amount of attention which it merits, and the result is that, instead of the completely forced system, which was introduced largely at last year's show, there is a tendency to adopt a semiautomatic system which requires no attention on the part of the driver, and yet avoids the method of drilling the crankshaft and other parts inevitable with the forced system. Daimler, Wolseley, Minerva and many more have the oil splashed to the bearings from troughs into which the ends of the connecting rods dip, and which are kept supplied by a pump situated at the bottom of the base chamber. As the troughs have only a limited capacity, it is impossible for excess of oil to reach the pistons, and so to cause a smoky exhaust, while at the same time the troughs will always be kept filled as long as there is sufficient oil in the engine to fill the pump.

High-Tension Magnetos Almost Universal—Regarding ignition, high-tension magnetos are, of course, all but universal, and it is noticeable that the magnetos are much smaller in size than hitherto. The Albion and Lanchester still pin their faith to the low-tension magneto, with make-and-break on the engine, and some of the high-powered Italian cars have low-tension magneto, the special magnetic plugs. The small Italian cars, however, have high-tension magneto, usually without provision for advance or retard of the contact-breaker. With British cars, on the other hand, it is usual to fit a lever to actuate the magneto advance.

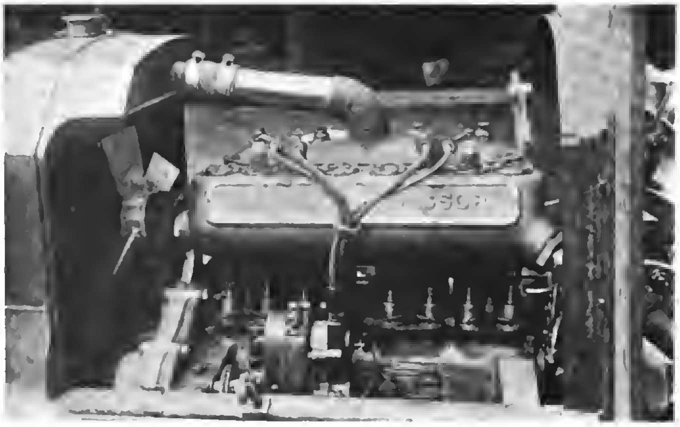
Quite a number of makers have abandoned the use of separate ignition systems—magneto and battery with coil—and instead have favored one or the other of the many dual magneto systems, in which the magneto distributor and the single set of sparking plugs are used for both ignitions. This was tried half a dozen years ago, but at that time neither the magneto nor the plugs were so reliable that it was safe to dispense with a second ignition system as a stand-by.

Two Sparks Created Simultaneously—One car—the Hobson—has adopted the double-pole plugs which have been introduced lately, so that two sparks are obtained at separate plugs from the single magneto. A distinct increase of power is said to result from this arrangement—particularly at high speeds.

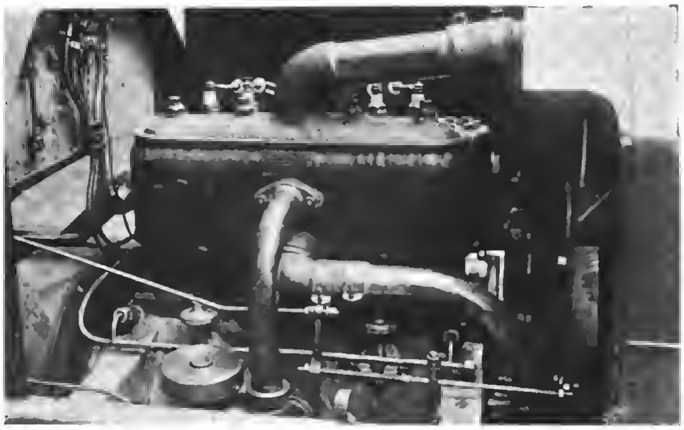
This point is worthy of investigation, for the tendency, at the present time, is certainly toward the use of high engine speeds. Due to this increased speed more attention has had to be paid to the matter of carburetion, with the result that, in addition to the use of air instead of exhaust pressure for the fuel feed to the carbureter, the latter is either of the mutiple-jet type or else has been equipped with an automatic air valve of such construction that the engine is not starved at high speeds.

For the cooling, thermosyphon circulation is growing in favor. When a pump is fitted this is almost always of the centrifugal variety, which is more quiet in action than the gear type. The piping, too, is much better arranged than has been the case in the past, when U-bends were frequent sources of air locks and overheating troubles. There are fewer radiators of the gilled-tube type, flat copper tubes being used instead. Experiments have clearly shown that the latter are more efficient, besides being lighter in weight. Fans are still of all shapes—some being made merely of flat pieces of steel, while others are aluminum castings of approved propeller form. In many cases the fan is driven by spiral gearing, from the pump and magneto cross-shaft, thus enabling the troublesome leather belt to be dispensed with.

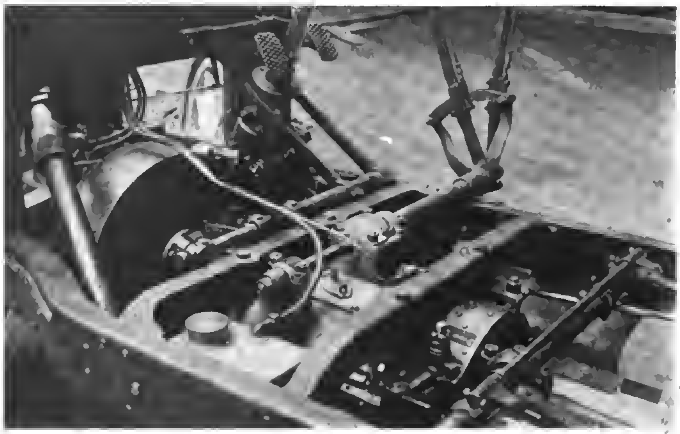
Leather Cone Clutches on the Gain—Leaving the engine, a review of types of transmission gear may be given. The increased flexibility of the engine calls for less work from the clutch, so that the simpler leather cone form is maintaining its position. Disc clutches are not increasing in numbers, but there are several new cars with the contracting-band type. As usual, there is a clutch of the hydraulic type which is said to be very efficient and to enable the gearbox to be omitted, but it has yet to prove its claims.



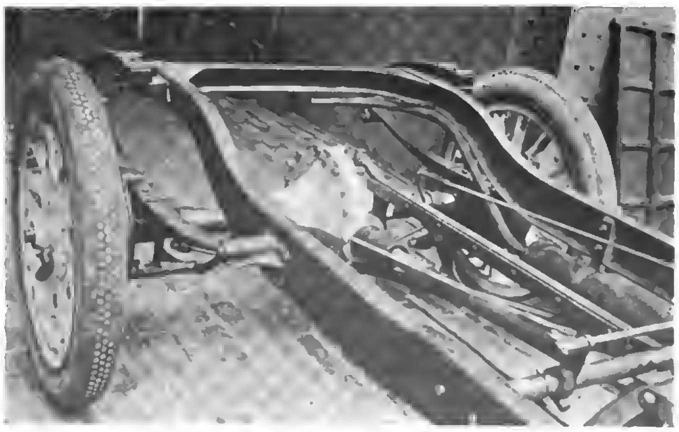
Panhard 12-H.P. Monobloc, Valve and Magneto Side



Panhard 12-H.P. Monobloc Engine, Carbureter Side



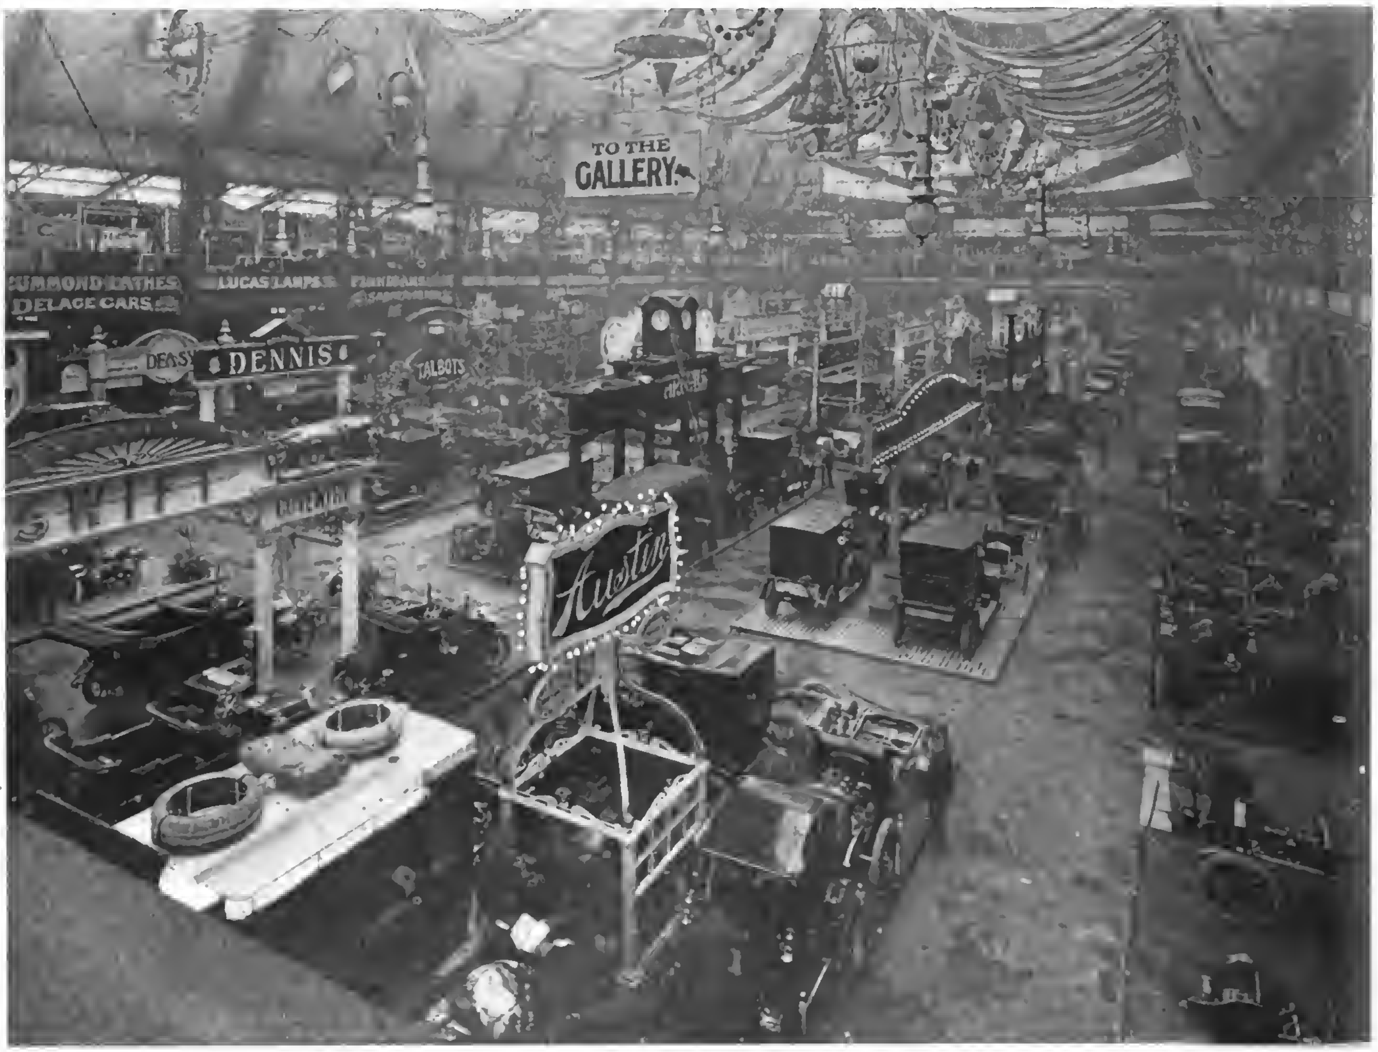
Clutch and Gear Box of Panhard 12-H.P. 4-Cylinder



Rear Axle of Panhard 4-Cylinder Shaft-Driven Car

The engine improvement is also the reason why on many cars there are now only three speeds instead of four. Where four speeds are provided, the third is usually direct drive, and the fourth geared up for fast running. The gate change is all but universal, examination revealing only the Renault and Delaunay-Belleville with the old quadrant type. At the rear axle worm driving is rapidly becoming popular, quite a dozen cars being so equipped. Opinion seems evenly divided as to whether the worm should be above or below the worm wheel, the latter giving better lubrication, but at the expense of reducing the road clearance. Chain drive is all but extinct.

Torque and radius rods are likewise a matter upon which there is much diversity of opinion. Many firms—such as the Itala, Hotchkiss, and Daimler—have no fittings of this kind. relying on the rear springs to take the drive, while other firms of equal standing—Fiat, Renault, and Napier—invariably fit torque rods. The tendency, if any, seems to be in the direction of dispensing with all rods.



General View of the Olympia Automobile Show, Which Excelled All Former British Exhibitions

Wire Wheels Growing More Popular Daily—Wheels of the wire type are growing greatly in popularity, while half a dozen forms of detachable wheel are to be found. Similarly front wheel brakes seem likely to come into general use, for such firms as Arrol-Johnston, Crossley, Motobloc, and Sheffield-Simplex fit this type on all cars. On other cars a band brake is fitted on the propeller shaft and internal-expanding brakes at the rear hubs. In some cases the latter are actuated by the foot pedal, reversing the customary arrangements.

To deal finally with completed cars, there has been an extraordinary craze for torpedo bodies. Examples of various designs are to be found on almost every stand, but there are few that could be called pleasing in appearance. This body seems to suit the Renault bonnet best. Several British cars—the Deasy, Arrol-Johnston, and Sheffield-Simplex—have adopted Renault lines, so that there must evidently be a demand for cars of that appearance. Covered bodies of many types are staged, but these will be dealt with later.

AMERICANS TOUR IN AMERICAN CARS

A feature of the development of foreign touring is the number of Americans who now visit Europe in American automobiles. Everything has been made so simple by the various touring associations that the American automobilist plans for a tour through Europe with as little fear of difficulties as if he were about to make a run through the Berkshires. This is largely due to the establishment of European branches by American manufacturers, keeping in stock all the repair parts.

The extent of this movement is shown by the fact that three leading factories have opened Paris touring bureaus in the last two years. N. S. Goodsill, in charge of the Pierce-Arrow Motor Car Company's Paris branch, reports 112 automobiles of that make in the first nine months of the year and an estimate of 125 for the whole year. "The greater number of automobiles are the large six-cylinder models, carrying five to seven persons," he states. "They usually remain in Europe from six weeks to two months, visiting France, Germany, Italy, and England principally. Intending tourists should obtain membership in the Touring Club of France before leaving New York, and at the same time secure a triptych for passing the French, Italian, or German customs if they land in one of those countries.

WHAT M. C. A. RECOMMENDS TO INTERNATIONAL CONFERENCE

THE Manufacturers' Contest Association wherein are represented all those American makers who are concerned in competitive events, has supplied the Automobile Club of America (which serves as the spokesman for this country in the international conference) with a definite consensus of opinion of what is desired in the way of international racing rules for 1910. The recommendations call for the participation of stock cars or stock chassis only, in international events, same to be classified according to piston displacement and minimum weight.

This logical and advantageous classification has given excellent satisfaction in this country, and the ideas of the American makers will be presented by William S. Hogan, the A. C. A. delegate, at the meeting to be held December 7 in Paris. These are the recommendations of the M. C. A.:

First: That only bona fide stock cars or stock chassis be eligible for entry in international events.

Second: That cars entered in international events be classified as follows:

Open to any chassis which is in accordance with the definition of a "Stock Chassis" and in accordance with the following table of piston displacement and minimum chassis weights:

Division	Cu. In. Piston Displ.	Minimum Weight in Lbs.
1	160 and under	1,200
2	161 to 230	1,500
3	231 to 300	1,800
4	301 to 450	2,100
5	451 to 600	2,400
6	601 and over	2,600

No car shall compete in any class above that to which its weight entitles it.

These recommendations are along the lines which will govern automobile competition in America for the coming year, with the possible exception of the larger classes. As the American manufacturers will no doubt build "stock cars" up to the limit of each of these piston displacement classes, should a similar classification be adopted internationally, it would enable foreign and American cars to compete on even terms and should serve to stimulate international competitions.

HEMERY'S REMARKABLE WORLD'S RECORDS AT BROOKLANDS

LONDON, Nov. 15—In view of the approach of Olympia, several makers worked hard at Brooklands in the endeavor to set up new records. Two performances, in particular, are very creditable. A stripped 60-horsepower, six-cylinder Thames chassis was driven by Smith on Friday last with an eye to the long-distance records. The car ran well throughout, and only one stop was made, to change a rear tire, was occasioned during the 300-mile run. The new records are as follows:

50 miles	34:02	88.1 m.p.h.
1 hour	89½ miles	89.5 m.p.h.
100 miles	1:06:54	89.7 m.p.h.
2 hours	173¼ miles	86.7 m.p.h.
200 miles	2:17:56	87.1 m.p.h.
3 hours	261⅞ miles	87.3 m.p.h.
300 miles	3:30:18	86.0 m.p.h.

Probably the most noticeable thing about these new figures is the remarkable evenness of the running, the average in miles per hour differing but little for three consecutive hours. Thus, for the first hour, the average of 89.5 differs from the figure for the second 60 minutes by but 2.8 miles. During the course of an additional hour's driving the rate of speed was so improved as to bring this up to 87.3 miles, a raise of .6 miles, and reducing the difference between the multiple hour figure and the first hour figure to 2.2. Whatever else it may be called, this is remarkably consistent driving, and redounds to the credit of the driver, who is practically unknown outside of this country. The new records, too, are to the credit of a car which is little known outside of the home country and the colonies, the name being a stranger to the Continent and America.

On the same day Hemery ran his 85-horsepower Benz for the short records, but deferred his final attempt for Monday. On this day he met with more success and succeeded in lowering all existing figures, beating the flying kilometer record, which has stood to the credit of Marriott since the Ormond-Daytona meet of 1906. Hemery's official times are:

Half-mile, flying start	14.08 secs	127.84 m.p.h.
Kilometer, flying start	17.76 secs	125.94 m.p.h.
Half-mile, standing start	25.57 secs	70.41 m.p.h.
Kilometer, standing start	31.32 secs	71.42 m.p.h.
Mile, standing start	41.47 secs	87.24 m.p.h.

A noteworthy thing about both attempts at the flying start records is that the longer distance record is at a higher speed than the shorter one. In this the flying German did not entirely outdo the American, for the average speed of the latter for the mile, made on the same day and at the same time and place as the now-broken kilometer record, was at the rate of 127.65, which Hemery just barely changed. The latter was the official fastest rate of speed, surpassing even the mark made by Demogeot, when the latter won the speed crown. The figure made then was but 123.3 miles per hour, so that Hemery now not only holds the distance, but the average speed record as well.

BIG THINGS EXPECTED AT INDIANAPOLIS SPEEDWAY

INDIANAPOLIS, Nov. 22—A race meet over the new brick surface of the Indianapolis Motor Speedway probably will be held on December 11. The course is now about half paved, and it is believed it will be completed about December 5. The meet will include everything from one-mile trials to establish a new track record, to a 1,000-mile race.

Ernest A. Moross, director of contests, has been induced to withdraw his resignation, which was to have become effective on November 15. He is now at work preparing the program for the proposed meet. As soon as he was in a position do so, the dates for the coming meet, the first on the brick surface, were announced. The first meet is scheduled for either December 10 or 11, to be decided within a day or two, and depending partly upon the ability of the paving contractor to finish the brick paving.

It is said that the services of all the record breakers at Atlanta and New Orleans have been secured for this meet, at which nearly every record mark from the quarter mile up to the 1,000-mile will be tried for. The competitors will be divided into the usual classes, 1, 2, 3, 4 and 5, as well as the free-for-all. In the shorter events, up to 50 miles, the free-for-all competitors will be started first, and followed by the class cars. In the longer events large fields are figured on, up to 15 cars per event. In all of these events no entry fee will be charged, the expense of holding the meet being met wholly by the grandstand admissions.

When interviewed relative to the coming record-fest, Mr. Moross was very confident of a speed of two miles per minute for the new track, not alone for a mile or two, but maintained for many successive miles. He has just returned from Atlanta, which track he admitted was very fast, much faster than the old Speedway surface, but not as fast as the new brick covering.

MARMON STARS IN NEW ORLEANS GOOD ROADS RACE MEET

NEW ORLEANS, LA., Nov. 21—Ray Harroun, in his Marmon stock car, proved the bright particular star of the Good Roads meet of the New Orleans Automobile Club. He won two firsts and two seconds in the four events which he entered on the first day, and one first and two thirds in three events of the second day.

The first day's racing had a slight scarcity of entrants, due to the non-arrival of a carload of machines, belonging to Barney Oldfield and other prospective competitors, which had been shipped from San Antonio. However, the weather was ideal, and a fairly large crowd turned out. The track seemed in good condition, but did not produce quite the speed expected, as no records were broken.

The feature of the afternoon was the second event, a 20-mile race for stock cars, in which the principals were the Marmon, Aitken's National, and Basle's Renault. Mile after mile these three cars were bunched, many times passing the grandstand wheel and wheel. Harroun finally moved into the lead, winning by two lengths from Aitken.

The 50-mile race started out in the same fashion, but tire trouble and minor accidents soon put many of the contestants out of the running, and spread out the others. Harroun finshed with 10 miles to spare in 54:00 3-5. He ran a consistent race, without a single stop. Summaries:

FIVE-MILE MATCH RACE

Pos.	Car	Driver	Time
1	Chalmers-Detroit	Cowell	7:12
2	Oldsmobile	Benzie	

TWENTY-MILE STOCK CHASSIS, A. A. A. (Class 2, Piston Displacement 301 to 450)

1	Marmon	Harroun	21:28 2-5
2	National	Aitken	
3	Renault	Basle	

FOUR-MILE LOUISIANA CHAMPIONSHIP

Open to Equipped Cars Owned by Citizens of Louisiana; Prize, Gov. J. Y. Sanders' Trophy.

1	Buick	Walker	6:48 2-5
2	Ford	Murphy	

TEN-MILE HANDICAP FREE-FOR-ALL

2	Marmon	Harroun (scratch)	
3	National	Aitken (scratch)	

FIVE-MILE FREE-FOR-ALL

1	National	Aitken	5:25 1-5
2	Marmon	Harroun	
3	Renault	Basle	

FIFTY-MILE, TWO CLASSES (Class 2, Piston Displacement 301 to 450; Class 4, Piston Displacement 161 to 230)

Prizes, $50 to Winner; $25 to First in Each Class.

Class 2:

1	Marmon	Harroun	54:00 3-5
2	Renault	Basle	

Class 4:

1	Marmon	Harroun	54:00 3-5
2	Chalmers-Detroit	Cowell	

Oldfield Appeared the Second Day—The missing carload of racers appeared late Saturday afternoon, and were quickly put in condition to participate. Barney Oldfield brought out his big Benz and attacked the one-mile record for the track, held by Ralph De Palma at 0:54 1-5. Barney's dash around the oval clipped off the superfluous fraction and set a new record at 0:54 flat. In an effort to lower the 50-mile record the Benz blew out a tire on the eighteenth mile, and the trial was declared off. The first 15 miles were covered in 14:04.

Kirscher, driving W. H. Pickens' Darracq, won the 10-mile handicap from Harroun and Aitken in 10:35, and lost a five-mile match race with Oldfield only by about the "thickness of a tire." The time was 5:17 3-5. Kirscher made the fastest 10 miles of the day in the free-for-all handicap, his time being 10:16 3-5. He finished second to Basle, the latter having 1:15 handicap.

In the last event of the afternoon, the 100-mile race, Harroun came into his own again. Aitken held the lead for 80 miles, having a lap on Harroun at that distance, but he had ignition trouble and was forced to withdraw. Summaries:

TEN-MILE HANDICAP

Pos.	Car	Driver	Time
1	Darracq	Kirscher (scratch)	10:55
2	National	Aitken (25 sec.)	
3	Marmon	Harroun (scratch)

MANY ACCIDENTS MAR SAN ANTONIO RACES

SAN ANTONIO, TEX., Nov. 20—While the automobile races held here this week were very exciting, and a high grade of sport was furnished the spectators, the sport was much marred by the accidents, which not only were dangerous to the competitors, but by narrowing the field, reduced the fierceness of the competition.

Robert Burman had a very narrow escape in the six-hour race when his Buick overturned. The car turned a complete somersault, but, fortunately, "Bobbie" was not injured. Barney Oldfield started at the wheel of a Knox, but a broken connecting rod soon put him out of the running. One of the Stoddard-Daytons broke a front wheel, and a Jackson, which had been following too closely, had to be driven over the banking to escape another collision. The six-hour race was won by Benjamin Johnson.

CHARLESTON, S. C. WANTS CONNECTION WITH SOUTHERN NATIONAL HIGHWAY

By M. B. Paine, Jr.

Historic City of the South.

CHARLESTON, S. C., Nov. 22—Among the most attractive cities in the South, and one that should not be missed by motorists, is Charleston, S. C., which, with its historic interest and natural beauty of situation and surrounding, holds a position not to be surpassed by any of the other cities. Due to a lack of interest in obtaining better roads, the development of automobiling has perhaps been a little bit slower here than elsewhere, but an entirely new era is dawning which promises to put the "City by the Sea" in the foremost ranks of good roads and motoring enthusiasm. Inspired and encouraged by the enthusiastic good roads campaign now in force through the South, the Charleston Automobile Club is taking active steps to secure the cooperation of other towns and cities to build a highway connecting this city with the New York-Atlanta highway, through Columbia, S. C., and thus to open up the shortest way for Northern auto-tourists wishing to go by road to Florida by way of Charleston and Savannah, Ga.

On the Road to Summerville.

Local good roads work is under the supervision of the Charleston and Summerville Highway Commission, and the Sanitary and Drainage Commission, in both of which Col. James Cosgrove is an active member. The efforts of these two commissions have resulted in building fine cement gravel highways extending in two directions from the city. The road to Summerville, the famous Winter resort in the pinelands, is the most popular and will be part of the projected highway connecting this city with the New York-Atlanta route.

Leaving the western part of the city over the Ashley River bridge, the other highway will pass through the largest truck-farming districts in the United States, where vegetables and fruit are shipped by hundreds of carloads all over the Eastern and Middle States. This road, after crossing five rivers, leads to Savannah, Ga., a distance of about 130 miles from this city, paralleling most of the way the tracks of the A. C. L. R. R., over which the entire Northern tourist travel goes to Florida. The working up of this highway will be due to the continued efforts of the Savannah Auto Club and the local club.

Another roadway which in time will be taken up for improvement is the one leading out of the city over Cooper River by the ferryboat of the Charleston Consolidated Light & Power Company, to the mainland known as Mount Pleasant. This road skirts the eastern coast of the State, passing through many beautiful old plantations, where rice and cotton are plentiful; through many Winter homes, including the famous reserve of the Santee Hunting Club, where the finest duck-shooting is enjoyed; through many small towns and seacoast ports,—McClellanville, Georgetown, Conway, and across Carolina to Wilmington.

During the tourist season, probably the most popular run is to Magnolia-on-the-Ashley, usually called Magnolia Gardens, known to nearly all tourists in the South as the most unique and beautiful display of azaleas of every hue in America. The road to this place runs west from the city over the Ashley River bridge, following the river for about fourteen miles, passing the gates of many beautiful Winter homes, with their long straight avenues of moss-covered oaks. This is also a popular run to Summerville, being a more beautiful, though longer road than the official highway, making a circuit with the latter of about 52 miles.

Over this Ashley River road was held probably the first endurance run in the South, four years ago, to Summerville. The good results of this run are shown in the greatly improved condition of the road. In the city itself the attractive points both historic and modern are numerous enough to bring every year a constantly increasing number of visitors and tourists. Fort Sumter,

Convicts Build Roads in S. C.

Built Before the War

situated on a small island in the centre of the finest harbor along the coast, no doubt represents the most historic interest, while in the U. S. navy-yard on Cooper River, and the forts and batteries on the islands surrounding the harbor, the visitor sees the vast amount of attention Uncle Sam is giving to this city, showing its great importance.

Many beautiful old residences and churches offer to those interested, types of architecture and methods of building not seen anywhere else in America. Although the city has been through many misfortunes, due both to man and to nature, it still possesses fine examples of houses built from material brought from England before the American Revolution. The surrounding islands also offer many fine beaches for those fond of racing, the best example being the Isle of Palms with a nine-mile beach fully equal to Ormond-Daytona. Two meets have been held on this beach, the times showing it to be very speedy.

The automobile situation is very good considering the reserved and conservative nature of the people who, though comparatively wealthy, are not ostentatious. Over two hundred cars have been sold and registered here, ninety per cent of this number in the last year and a half. Most of the machines are of the popular-priced touring variety, and there are no foreign cars at all. Four or five garages and repair shops represent the business end of the industry in motor cars—The Motor Supply Company, 161 Meeting street, Overland cars; The Urmy Cycle Mfg. Company, 130 Meeting street, Buick and E-M-F; the Automobile & Marine Motor Company, 249 Meeting street, Ford, Mitchell, Chalmers-Detroit; M. B. Paine, Sr., 47 Meeting street, White cars.

The recent forming of the Charleston Automobile Club promises to enliven the interest very much, and increase the number of cars used. The club is planning its initial run for Thanksgiving Day, probably to Summerville, to enjoy the cordial hospitality of the Pine Forest Inn, well known to all who tour through the South.

FLORIDA'S WEST COAST ON AUTO MAP

St. Petersburg, Fla., Nov. 20—The cities of this section of Florida have taken up the combined automobile-good roads movement with great enthusiasm, and are busily engaged in "discovering" each other by the newest form of transportation.

Last week a party composed of Ed. T. Lewis, with a Cadillac; Horace Williams, with an E.M.F., and Will Ramm, with a Mitchell, left this city bound for Clearwater. The St. Petersburg-Tampa road was followed until the macadam road from Clearwater to Green Springs was reached; then the three mamachines ran into Clearwater, and thence to Dunedin over the fine macadam road from Large to that city. The stretch of road from Clearwater to Dunedin is probably the finest five miles of macadam in the State, and with but one sharp turn makes an ideal speedway. All the way the road runs parallel to the beach, not more than a hundred yards from the water. The gulf is always in plain sight beyond the keys that mark off Clearwater harbor.

The automobile owners of the city have formed the St. Petersburg and West Coast Automobile Club. By-laws have been adopted, and the following officers elected: Dr. F. W. Wilcox, president; Ed. T. Lewis, vice-president; A. W. Fisher, secretary; Horace Williams, treasurer. A board of governors was also chosen, consisting of George Presstman and Drs. Hume, Rouse, Turner and Brown. A committee headed by Mr. Lewis has conferred with the county commissioners in Tampa, and received much encouragement from their attitude regarding road improvement on the West Coast.

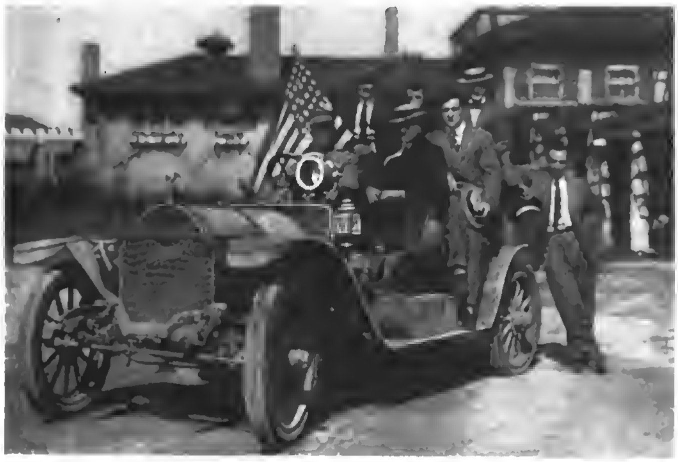
A Home near the Santee

What the Clubs Are Doing These Days

BALTIMORE AERO CLUB AFFILIATED WITH AERO C. A.

BALTIMORE, Nov. 21—President Jerome H. Joyce, of the Aero Club of Baltimore, has received from the Aero Club of America articles of affiliation of the local club, together with a letter from the national body requesting that the papers, which were sent in duplicate, be signed and returned to the national body. These will be forwarded to New York within a few days by the local club and, with favorable action by the national organization, the Baltimore Club will have become an active factor in the International Aeronautic Federation.

Members of the Aero Club of Baltimore are hustling to raise the $50,000 fund which this city is expected to contribute toward the project to bring the big international aviation meet in 1910 to some site between Baltimore and Washington. President Joyce has also appointed 48 additional members, all representative citizens of the city, of the local committee which is intrusted with the work of raising this guarantee fund.



When the Mitchell Ranger Visited Chicago Friends

With a cargo of newspaper men at the South Shore Country Club. Frank X. Zirbles at the wheel; Joseph E. G. Ryan ("Inter Ocean") and R. J. Finnegan ("Journal") on the fender; in tonneau, left to right, E. G. Westlake ("Evening Post"), Davis Rotroff ("Daily News") and J. C. Patterson ("Examiner"). Walter A. Birmingham ("Inter Ocean") is leaning against the car

PROMINENT BAY-STATER TO BECOME CALIFORNIAN

BOSTON, Nov. 20—A. E. Morrison was the guest of his motoring friends Thursday evening at a farewell banquet tendered him at the Bay State Automobile Association on the eve of his departure to make his home and engage in business in California. Mr. Morrison has been engaged in the trade in Boston almost since there was an automobile trade, being manager of the Peerless branch for several years, and afterwards agent for different cars. More recently he has been manager of the Taxi Service Company, of Boston. He goes to California to take up the management of the Studebaker Bros. branch in San Francisco. Until he was injured in a road race at Lowell several years ago Mr. Morrison was prominent as a race driver.

At the banquet James Fortescue, secretary of the club, presided, and J. W. Bowman of the local Stevens-Duryea agency presented to Mr. Morrison, in behalf of the Bay State Association members, a gold watch fob bearing the insignia of the club. C. J. Bailey presented to him a handsome diamond scarf pin. Other speakers included E. A. Gilmore of the Whitten-Gilmore Co.; J. W. Maguire, the Pierce agent; E. P. Webber of the Diamond tire branch; Kenneth Skinner and J. S. Hathaway of the White Co.

MILWAUKEE'S SHOW PLANS SPELL SUCCESS

MILWAUKEE, WIS., Nov. 22—The second annual Milwaukee motor show, to be held under auspices of the Milwaukee Automobile Club from Feb. 22 to 27, inclusive, will not be a "local" affair, but of national importance, if the flood of applications for space is to be taken as an indication of its extent.

President Clarke S. Drake, of the club, who is general manager of the show, says that plans are being considered to make the show a genuine "Motor show" in every sense. Motor boats and the like will be given full representation.

This plan is feasible this year through the use of the new $500,000 Milwaukee Auditorium, covering an entire city block. There are four halls, in addition to the main hall covering a half block, each as large as the average theater. The main hall seats 8000 comfortably and the smaller halls 1500 each.

The accessory department will be one of the features of the show. Motors, engines and parts will be given adequate representation also.

CHRISTMAS DECORATIONS FOR COLUMBUS SHOW

COLUMBUS, O., Nov. 20—The committee of arrangements for the automobile show to be given December 25 to January 1 under the auspices of the Columbus Automobile Club, has arranged for the decorations to be white and green and to be in accordance with the Yuletide. All the decorations, including flags and bunting, will be fireproofed before placed in position, and in addition a squad of firemen will be detailed to watch the hall constantly.

The admission price has been reduced from 50 to 25 cents, and it is expected to have at least 60,000 visitors. Special rates will be given on all railroads for the occasion.

In all there is 14,451 square feet of space for the automobile exhibits and a large space for the accessories. It is stated that several of the automobile exhibits will be taken intact to the Grand Central Palace show in New York the following week.

LOUISVILLE HUNTING BUILDING FOR SHOW

LOUISVILLE, KY., Nov. 22—It is likely that Louisville will have an automobile show next Spring. Eugene Straus, President of the Louisville Automobile Club, is behind the movement and some definite action will probably be taken at the next meeting of the club. The armory, the largest building in Kentucky, is regarded as an ideal place for an automobile show, the structure covering an entire block. The basement could be used for accessory exhibits. Additional space here will allow twice the size of show held last year at the Coliseum building which was recently destroyed by fire.

A new home for the club is now practically assured, as the membership campaign was a success, seventy-five new members being added.

A. C. OF CINCINNATI'S SHOW, FEB. 21-26

CINCINNATI, O., Nov. 22—Under the auspices of the Automobile Club of Cincinnati, an automobile show will be held in Music Hall, the largest building suitable for the purpose in the city, February 21-26. No effort will be spared to make the show a pronounced success, and the club announces that any profit resulting from it will be expended in the interest of autoing and autoists in this section. Jesse Lippencott, whose headquarters are at the Gibson House, is at the head of the committee in charge of the exhibits, and any requests for information will receive his prompt attention. Although the date has just been announced, many firms have signified their intention of exhibiting.

ROADS BUILDING NEWS FROM ALL OVER THE COUNTRY

INDIANA ROAD BONDS FOUND UNCONSTITUTIONAL

INDIANAPOLIS, Nov. 22—A severe blow has been given road building in Indiana through a decision of the Indiana Supreme Court holding that all road laws providing for the payment of the construction of highways by bonds to be paid in turn by township taxation are unconstitutional. This decision was rendered last week, and practically all road building in the state has stopped, and there is considerable doubt as to the validity of millions of dollars worth of bonds that have been issued by townships.

For many years the method of road building followed in Indiana has been for the county to issue road improvement bonds, the county being reimbursed by a township tax levy. Thus all persons living in the township were taxed for the construction of a road in any part of the township.

This law has applied only to townships having incorporated towns of less than 30,000 inhabitants, and the Supreme Court holds that this makes the law class legislation, and, therefore, unconstitutional. The decision was reached on a case appealed from Hamilton County, where the Circuit Court refused to enjoin the county commissioners from ordering a road to be paid for by township taxation.

The only method of road building now left is to build it by direct assessment against all property within one mile of the road thus constructed.

KENTUCKY'S GOOD ROADS AMENDMENT

LOUISVILLE, KY., Nov. 22—The South has without question a decided advantage over the North in the use of automobiles, owing to the fact that cars can be used the entire twelve months of the year, 'while in the North climatic conditions make this almost impossible. It is true that the roads in some seasons are in rather bad condition, but the whole South has waked up to the vital importance of good highways and atuomobiles as one of the most modern methods of increasing wealth.

The vote on the good roads amendment to the constitution of Kentucky was a disappointment to those interested in the betterment of the State's highways, and it is apparent that the apostles of good roads have much to do in the way of evangelization. There seems a slight chance that the amendment has been adopted, but if such proves the case, it will be by a close margin. The result will not be known until the official count has been completed. Should the amendment be carried, it is evident that a number of the counties will be slow to take advantage of its provisions. The small vote on the proposition in many counties and adverse majorities in others are due to popular indifference and to the widespread fear of "tinkering with the constitution." Some of the wealthiest and most progressive counties of the State voted overwhelmingly against the amendment. Other counties of which not so much was expected gave the proposition a surprisingly good support.

OHIO HIGHWAY DEPARTMENT TO ISSUE STATE MAP

COLUMBUS, O., Nov. 20—The Ohio State highway department will shortly issue a booklet containing a complete road map of the State by counties. The department has been busy on the work for months and assurances are given that it will be one of the most complete road maps ever worked up. Every turn in the road, bridge, railroad crossing and rough place in the road will be shown. It may be issued in colors later. This booklet and map will be of unusual interest, and great value to all automobilists obliged to travel by motor car through Ohio.

LANCASTER CLUB ATTACKS NEGLIGENT ROAD OFFICIALS

LANCASTER, PA., Nov. 20—The good roads committee of the Lancaster Automobile Club has filed exceptions to the reports of the road supervisors of Eden, Penn, Manheim and Lancaster townships, of Lancaster county. Several weeks ago Charles G. Baker, solicitor for the club, sent a circular letter to every road supervisor and every township constable in Lancaster county, calling their attention to certain Acts of Assembly relating to sign-boards and the removal of loose stones from roads.

The first of these acts provides that the supervisors shall cause posts to be erected at the intersection of all public roads in their respective townships, with boards affixed bearing an index hand and inscribed in legible characters with the name of the town to which the road leads, and the distance in miles; and also, that if any supervisor shall, after ten days' notice, fail to put up or put in repair such sign-boards, he shall be liable to a fine of $20. The "loose stones act" provides that the supervisors shall have removed from the public roads all loose stones at least once a month during May, June, August and October. For failure to do this a fine of $10 may be imposed.

After the warnings had been sent out the club committee had various members inspect the roads and report on them, witnesses being taken along to secure a perfect case. As a result of these investigations the club took the action stated above, filing exceptions to the returns of four of the forty townships. The matter will be taken up in the November term of the Quarter Sessions Court.

New Road Through Crawford Notch, in the White Mountains

WISCONSIN'S GOOD ROADS ENDEAVORS

MILWAUKEE, WIS., Nov. 22—M. C. Moore, of Milwaukee, president of the Wisconsin State Automobile Association, urged the employment of convict labor in highway improvement and good roads construction, at the session of the special Wisconsin legislative committee investigating the good roads problem, at Milwaukee. Several prominent owners claimed this system to be highly unsatisfactory and that it would add to the difficulties.

Chairman Jones, of the committee, closed a lengthy and excited discussion by saying: "Once you get this work started you will find plenty of men who will make it a business."

Townships in the vicinity of Fond du Lac and West Bend are taking the lead in erecting guide boards, as demanded by a law passed by the last legislature. These boards were to have been placed by November 1, but farmers claimed that harvest work halted them and they have asked for a little more time. In Fond du Lac and Washington counties, a new type of guide board and standard is being used. The post is a hollow steel pipe, set in concrete, with a special bracket at the top, with room for six signboards. The post is being used exclusively in these counties. It is cheap and will last a life-time.

OHIO COMMISSIONER FAVORS ROAD SYSTEM

COLUMBUS, O., Nov. 20—State Highway Commissioner J. C. Wonders will soon issue a booklet containing all the laws relating to highways and road improvement. The booklet will be issued to show every community in the state the method of securing appropriations for road improvement, and the laws that provide for their maintenance. The booklet will contain full explanation of the working of the designing board.

Commissioner Wonders, in a public statement, favors the adoption of a general plan of pike repairs and road maintenance modeled after the system in vogue in France, which, he says, is of the greatest efficiency of any in use in any part of the world. The Ohio General Assembly will be called upon to enact some law in that direction at its next session.

LONG ISLANDERS ANNOUNCE 1910 NOMINEES

BROOKLYN, N. Y., Nov. 24—The Long Island Automobile Club held its regular monthly meeting at the clubhouse, 920 Union street, Wednesday evening. The entertainment took the form of a beefsteak dinner. It was a busy evening, as the program following will indicate: Music and preliminaries at 6 p. m., meeting at 6:30, banquet at 7, presentation of silver cups at 8:15, addresses at 8.30 and advanced vaudeville at 9:15.

At the meeting, besides the regular business of the club, forty applications for membership were favorably acted upon, and the nominating committee reported nominations as follows:

For president, Allen C. Alderman; for vice-president, Louis T. Weiss; for treasurer, Charles C. Cluff (renominated); for secretary, C. Stewart Cavanagh; for governors (two years' term), Frank G. Webb, William Schimpf and Dr. C. B. Parker; for membership committee, J. Pell Disbrow and William M. Alford. No opposition nominations are expected. The election will take place at the annual meeting, to be held December 1. President Webb declined a re-election, stating that business duties made its acceptance impossible. Nominee Alderman has been a most prolific member-maker.

HISTORIC BUILDING BURNS IN DETROIT

DETROIT, Nov. 22—The old Biddle House, in this city, which half a century ago was a notable hostelry, was burnt to the ground last week. The ground floor was occupied by a number of automobile concerns. The Firestone Tire Company lost about $20,000, the Jackson Automobile Company $2,500, the Republic Rubber Company $2,000, the Detroit Tire & Repair Company $1,000 and the Studebaker Automobile Company $1,000. These losses were fully covered by insurance.

WINNERS OF SAVANNAH-ATLANTA RUN

SAVANNAH, GA., Nov. 21—The winners in the Savannah to Atlanta endurance run have been announced by Arthur W. Solomon, chairman of the technical committee.

It was found that in Class A, for cars listing at $2,000 and over, Dr. Craig Barrow, driving a 24-horsepower Stevens-Duryea, had made the trip with a perfect score, which of course meant first prize.

In Class B it was harder to decide, and after going over the cars for the second time it was found that two were tied, these being a Crawford 30-horsepower, driven by W. C. Mahoney, and a Maxwell 30-horsepower, driven by Robert Brockett, Jr. The prize in this class will be divided.

Again in Class C the same trouble came over the technical examination as it did in Class B, and two cars were again declared tied, these being a Maxwell 10-horsepower, driven by E. G. Gager, and a Buick 22-horsepower, driven by E. A. Weil. The Maxwell in this class is the same car that made a perfect run from New York to Atlanta. The prizes in this class will be divided.

Next Run From Savannah to Jacksonville

It seems certain that the next run to be given by the Savannah Automobile Club will be to Jacksonville, Fla. If this run is arranged it will work out the last link to blaze the way in the New York to Jacksonville highway.

The run may be in the latter part of April or the first part of May. The distance is something like 162 miles, and can be easily made in nine hours, which, of course, would take less than a day. The entrants would be much more numerous than in the run to Atlanta, this because of the fact that concurrent with the Atlanta run, there were several other runs from Georgia cities. Entries would be received from all the cities along the road, and also from Jacksonville.

NEW BOOKS FOR AUTOMOBILISTS

"Sicily; the Garden of the Mediterranean"—Those modern gypsies, the automobilists, will find an inspiration in this latest volume from the press of L. C. Page & Company. Will S. Monroe, author of "Turkey and the Turks," and "In Viking Land," signs his name to this additional work of biography, as it were, of a land and its people. Mr. Monroe speaks interestingly of the history of Sicily, and of the origin, social conditions, religion, education, industries and art of its people. To each of the principal cities is devoted a chapter, not forgetting unfortunate Messina. Tourists will read with especial interest the chapter on "Hostelries, Brigandage and the Mafia." Hotel keepers appear to be of even a more predatory nature in Sicily than in other parts of the world, and their wiles are many and surprising—amusing, too, when one's self is not the victim. Brigandage, according to Mr. Monroe, has almost disappeared, and the Mafia is on the decline. The volume, printed on thick, tinted paper, is handsomely bound in cloth, and its 400 pages are enriched by innumerable full-page illustrations.

"Guatemala and Her People of To-Day"—Guatemala is virgin territory for the automobilist. Although comparatively near this country it is little heard of save when an occasional revolution finds a scant paragraph in the daily papers. "Guatemala and Her People of To-day," by Nevin O. Winter, is another of the publications of L. C. Page & Company, in its series of works on the various countries of the globe. Roads in this country of few accomplishments and great possibilities are in a most rudimentary condition; yet with development they must inevitably improve, and that time is not so far away. The awakening has already begun. Gautemala has extensive coffee plantations, and growths of rubber which might be developed to much profit, especially in view of the rising price of that article. Automobiles will no doubt play an important part in the future transportation systems of the country. This volume is a companion to the others of the Page series, and the typographical work is up to standard, illustrated with no less than 49 full-page plates.

THE LAW AND THE AUTOMOBILE

HOLDS NEW JERSEY LAW IS CONSTITUTIONAL

TRENTON, N. J., Nov. 19—The Supreme Court, in an opinion by Justice Reed, has sustained the constitutionality of the Frelinghuysen automobile law. The law was attacked principally on the grounds that it was an improper interference with interstate commerce. The White Company of New York sent R. H. Johnston, its advertising manager, through the State in a machine loaded with parts intended for the Philadelphia branch, so that the car was directly engaged in interstate commerce. The driver of the car was arrested for failure to comply with the provisions of the law.

The law was attacked on the following points:

First—The right of the State to license automobiles not according to true value, but according to the horsepower.

Second—Is this not a double tax, as the first tax is levied by taxing assessors?

Third—That the law puts automobiles in a special class for the purpose of taxation.

Fourth—That this is a tax on interstate commerce in violation of the Federal Constitution.

Fifth—This tax is a violation of the fourteenth amendment of the Federal Constitution, and

Sixth—That the act discriminated against citizens of other States because it compels the designation of an agent upon whom process may be served in this State.

Justice Reed bases his decision on the police powers of the legislature. He says that the automobile is a dangerous machine, and that the first duty of the State is to protect the public from danger to life and limb. He further says that the so-called taxing of automobiles is really licensing, as properly called under the Frelinghuysen law, and therefore not unconstitutional. He denies that anyone has an inherent right to use the highways for automobile travel. The opinion may be summarized on the following points:

These provisions (license fees) are legitimate exercises of the police power of the State, notwithstanding the clause in the statute that requires all fees, fines and penalties arising under the act to be paid to the State Treasurer, and to be apportioned by the State Road Commissioners for the repair of improved roads.

If it was necessary to regard these provisions as an intentional legislative imposition of a tax for revenue, they yet would not be unconstitutional.

The provisions requiring each non-resident owner of an automobile to designate an agent in the State upon whom process may be served in any action against the owner growing out of the operation of his registered machine in this State is not unconstitutional.

In view of the present need of a vigorous enforcement of these laws for the protection of all users of the highways, I am of the opinion that the condition imposed that a man who proposes to use our highways for motoring shall agree to submit himself to the courts of the State into which he comes is legal.

MARYLANDERS DRAFT PROPOSED AUTOMOBILE LAW

BALTIMORE, Nov. 21—Harmony was the keynote of the conference between the Maryland Automobile Commission, appointed by Governor Crothers to draft an automobile law for passage by the State Legislature, which convenes in January, and the Automobile Club of Maryland, at the club house last Wednesday evening. The long-sought compromise on the figures of taxation was made after a lengthy discussion, in which both members of the commission and the club participated. These are the rates decided upon:

For cars of 20 horsepower and under	$6
For cars of over 20 horsepower and not more than 40	12
For cars of more than 40 horsepower	18

It was also decided to fix the salary for the proposed automobile commissioner at $3,000 a year.

MASSACHUSETTS LAW OPERATIVE JANUARY 1

BOSTON, Nov. 20—By the new automobile law passed by the Massachusetts Legislature last Spring, the Highway Commission is permitted to begin its preparations for reregistering cars and reissuing licenses the first of December of this year, though the bulk of the law does not go into effect until the first of January. The commission is taking advantage of this provision, and has so far progressed with its plans, that it expects to be able on the first of next month to send out the new application blanks for both registration certificates and licenses, and to issue number plates as fast as applications are received. The commission has made this early preparation because of the fact that the new law requires almost revolutionary changes in the methods heretofore pursued. Up to this time, from the passage of the first automobile law in 1903 all private operator's licenses have been perpetual. There have been issued 34,702 of these licenses and the new law annuls them all. How many there are in actual use the commission has no means whatever of telling, but it is confident that at least half of them will be renewed and perhaps the proportion will be even larger.

Aside from having to renew all the licenses of private operators, no mean task in itself, the commission has to reregister the cars. There are over 23,000 of them in the State and probably many thousands will be registered immediately, as their owners will want to use them all through the Winter. And they must be reregistered on the new horsepower basis with fees graded from $5 to $25. In addition there is a large number of motor cycles to be reregistered.

The commission has made a change in terminology. "Private operator" is now merely "operator," and "operator for hire" is "chauffeur." No person under 16 years of age can receive an operator's license and no person under 18 years can receive a chauffeur's license. Persons to whom operator's licenses have been issued at any time during the past six years can obtain a new license under the renewal clause, paying 50 cents instead of $2, the fee for a new license. The application blank for a license contains no less than sixteen questions to be answered under oath, including date of birth, color, sex, height, weight, color of hair and of eyes, experience in driving motor cars, criminal record so far as motor laws are concerned if any, habits as to use of intoxicating beverages, physical or mental infirmities and familiarity with the law of the road.

NEW LAW PROPOSED FOR BUCKEYE STATE

COLUMBUS, O., Nov. 20—A bill has been prepared by Representative Ritter, chairman of the finance committee of the Ohio House of Representatives, providing for graduated fees for the registering of automobiles in the Buckeye State. The bill, which will be introduced in the General Assembly early in the session in January next, provides for a tax of $3 for all electric cars, $5 for all gasoline and steam cars up to 20 horsepower, $10 for all cars between 20 and 40 horsepower, and $15 for all above 40 horsepower. Trucks will be charged $5.

It is known that fully 25 bills will be thrown into the hopper early in the next session of the General Assembly, and the Ritter bill will probably be united upon by autoists to keep freak legislation from being placed on the statute books. The Ohio State Automobile department is of the opinion that the present law is sufficient. Mr. Ritter has come to the state department for suggestions, secured from experience.

There is some doubt if a law providing for different fees, based on horsepower will withstand the tests of constitutionality in the courts. In the present law, which was carried through all the tribunals of the state, the fee was declared not a license but only the exercise of police powers. It may be that increased fees will be construed as licenses, which is contrary to the Ohio constitution.

CHICAGO CLUB IN VARIED LEGAL ACTIVITIES

CHICAGO, Nov. 20—Directors of the Chicago Automobile Club have gone on record as favoring the erection of permanent gates at draw-bridges, and have appointed a special committee, consisting of F. W. Blocki, Allen S. Ray and T. J. Hyman, to investigate the matter. Secretary C. A. McDonald, who is also the club's legal adviser, will then draft an ordinance which the club will present to the city council for adoption. One of the features of this bill will be the suggestion that the gates be placed forty or fifty feet from the bridge.

Discussion of the tail-light law, which was scheduled for the meeting Thursday, was prevented by the fact that Secretary McDonald has been unable to find in the official reports of the council's proceedings any reference to the passage of such a measure, although it was reported in the daily papers.

More work was also given the legal-minded secretary in relation to the club's probe to find out what the various towns and villages in the vicinity of Chicago have done with the money collected from scorchers. This money is supposed to be spent on the improvement and repair of the highways. The club has been investigating this for some time, and has reason to believe that all the money has not followed the proper course. The city of Chicago reported that a considerable sum had been turned over to the park commissioners.

THE OHIO AUTOMOBILE LAW AND ITS WORKINGS

By FRED. H. CALEY, STATE REGISTRAR OF AUTOMOBILES.

WITH the advent of high-powered automobiles capable of being driven at a high rate of speed along the roads and highways of this State there arose the necessity of some method of regulating and identifying these motor vehicles. To that end the Ohio Legislature in 1908 enacted what is known as the Ohio Automobile Law, which becomes effective on June 10 of same year. It provides, in brief, that all motor vehicles shall be registered annually in the office of the Secretary of State by the filing of an application containing the correct name and address of the owner, and a detailed description of the car, together wtih a fee of $5 for each steam and gasoline and $3 for each electric automobile owned or hereafter acquired. The Secretary of State issues a certificate of registration or "license" card and two number plates bearing the distinctive number assigned to such motor vehicle which are to be conspicuously displayed, one in front and one in rear of the car.

The rates of speed at which motor vehicles may be legally operated are provided by the statute and each motor vehicle is required to be properly equipped with lights at night.

Under the provisions of this law as originally enacted all "licenses" continued in force for one year from date of issue. This involved considerable confusion and the last Legislature so amended the law that all certificates of registration now expire at the end of the calendar year for which they are issued. Certificates of registration issued in 1908 expire one year from date of issue and must them be renewed for the period from such date of expiration to January 1, 1910. The fee for registration cannot be pro rated for a part of a year, and certificates of registration and number plates are not transferable in any event, either from one automobile owner to another, or from one motor vehicle to another. An automobile owner is required to register each motor vehicle owned or acquired. An amendment to this statute will be offered when the Legislature convenes providing that in case of sale or transfer of ownership of a car the original owner may, if he immediately acquires another car, file a description of his new car in the office of the Secretary of State accompanied by a nominal fee of $1 and be re-issued the same number and number plates for his new machine.

The net revenue acquired from these registrations is converted into the State Treasury monthly and maintained as a separate fund for the improvement, maintenance and repair of the public roads and highways in this State and is apportioned as the State Highway Fund is proportioned by law.

The paramount object of this statute, however, is to provide for the absolute identification of the owner and operator of every automobile driven upon the roads and highways of this State. A full and accurate list of all the ledger records of this department is furnished to the clerk of courts in each county of the State, and additional registrations are furnished monthly. This list contains the name of the owner and his address, his registration number and a detailed description of his car and is provided with a numeral and a name index alphabetically arranged. In case of an accident occurring in a remote part of the State it is not necessary to write to the Secretary of State to ascertain the name of the owner of any automobile, as this information can be procured at the office of any county clerk.

One of the most beneficial results of the State law to the automobilists has been the elimination of what was known as the "city licenses." Heretofore each city in the State had a local license ordinance providing for the imposing of a fee of from $1 to $7.50 for a license on each automobile. The Supreme Court has recently decided that these city licenses are unconstitutional inasmuch as they conflict with the provisions of the State law.

Reciprocal relations have been entered into with the secretaries of States and automobile departments of other States, and Ohio "licenses" or number plates are now recognized in practically every State having automobile registration, with the exception of New Jersey and Maryland.

As a result of this statute there was converted into the State Treasury for the fiscal year ending November 15, 1908, the sum of $46,000 in round numbers, being the net receipts for the first four months' operation of the law. The net receipts for the year ending November 15, 1909, will approximate nearly $100,000.

By reason of letting all contracts for the furnishing of number plates and chauffeurs' badges by competitive bidding the expense of the department will be greatly reduced for the year 1910.

The department is conducted upon a strictly business basis, and we are endeavoring to insure a maximum amount of efficiency with a minimum amount of expense.

There are now registered in this department in round numbers twenty-three thousand owners, four thousand chauffeurs and about five hundred manufacturers and dealers.

The growth of the automobile industry during the past ten years is astounding. The city of Cleveland alone has nearly 5,000 machines, or nearly as many as in Toledo, Columbus, Dayton and Cincinnati combined. There are more automobiles in Columbus to-day than were operated in the entire United States eleven years ago. It is estimated that the total number of machines in the United States in 1898 was less than 1,200. Now there are over 180,000, and the manufacturers' associations estimate that during the year 1910 there will be made and put upon the market over 200,000 new cars, or 20,000 more than the entire output of all the factories in the country during the past ten years.

There is probably no class of citizens who are more intensely interested in good roads and who suffer more inconvenience from bad ones than the automobilists of this State.

A number of eminent silk hatted, faultlessly attired gentlemen have met from year to year in a so-called good roads convention. They have "resolved" and "resoluted" by endorsing various methods of road building and have made two-hour speeches in which everybody was urged to "co-operate" with everybody else, but the automobilists of the State have waited in vain, until now, to see the man with the shovel.

This convention, I take it, gentlemen, is a convention of actual road builders. You are not here for the purpose of passing compliments, or listening to platitudes, but to devise ways and means for improving the highways of this and every other State in the United States in the best and most ecenomical manner, and to that purpose the automobilists of Ohio, who are 25,000 in number this year and will be 40,000 next year, are ready to assist you. The automobile owners of Ohio do not object to paying a registration fee, but they insist that the revenue derived shall be devoted to this purpose. What we need, however, is not so much of an appropriation of revenue as an appropriation of brains. If we can convince the members of the Legislatures of the various States that the money appropriated for road purposes will be properly and judiciously expended there will be no trouble about ready money forthcoming to carry on the work.

Paper read before the National Congress of Road Builders, and the American Road Makers' Association Convention, Columbus, O., Oct. 27, 1909.

THEORY AND WORKING OF THE THERMOSYPHON*

By D. Siebenmann, M.E.

WITH reference to no other part of the modern automobile does there appear to be such an erroneous impression prevalent as with regard to the working of the thermosyphon system of circulation. Before taking up the subject, I must first refer to a scientific discussion regarding the need for the characteristic broad return pipe in order to create a great amount of space for the return flow, that has been dwelt upon by a well-known expert.

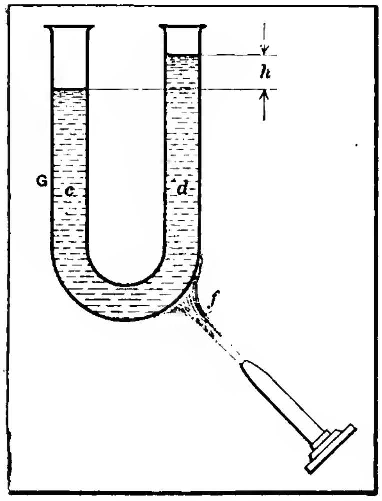


Fig. 1—Test tube, filled with water, showing flame from Bunsen burner playing against same

There are so many different parts of wholly variant nature to be designed and allowed for in the construction of an automobile, that it is quite conceivable errors may be made in the above form, and that without in any way reflecting upon the designer. Then woe to the builder—as in the automobile industry, unfortunately, it is at his door that failures are commonly laid—if he adopts something the operation of which is not entirely clear to him. The responsibility for numerous failures is due to the fact that the particular construction has been adopted without a sufficiently detailed investigation, its merits have been passed upon purely from surface indications of value, and this is especially the case where the thermosyphon is concerned. It just so happens that articles on this subject have fallen far short of covering it completely.

Data Throws Light on Former Unsatisfactory Results—The following, which consists of data compiled by the well-known firm of Renault Frères, serves to throw light on a number of things, and above all on the errors in the relation of the parts peculiar to this type of cooling system. At the outset, the results obtained were most unsatisfactory, and the conclusion was accordingly reached that sufficient cooling was not obtainable in this manner and this system was not available for use on the automobile. But this was entirely erroneous. By properly calculating the size of the various parts, taking into consideration all the necessary factors, which are now well known, any cooling effect desired is obtained.

In a definition of the term "thermosyphon" we have an expression that is about as far from being indicative of its real nature, as are many others to be found in automobile terminology. A much better term would be "heat-circulating." The word indicates that under the influence of heat, a circulation is set up, and it is quite apparent that heat is the moving force acting on the water. Experiments have shown the causes of this movement to be as follows: See Fig. 1. *G*, is a U-shaped test tube, the legs of which, *c d*, are filled with water; *f* is a Bunsen burner, the flame of which is directed against the leg *d*. The flame is allowed to play against this part of the glass until a definite relation of the surface of the water in this leg of the tube is established with regard to its loss in weight.

This will continue at the expense of the density of the water until a so-called thermal column of the height of *h* will be raised. The two legs *d* and *c* may then be joined at the height of *h* by a tube, so that the level will be restored, both columns then having the same weight, which will set up a circulation of the water. Here, then, is an explanation of the principle involved, showing the reason for the circulation. The driving power of the latter is indicated by the thermal expansion of the column, and the greater this driving power, the more lightly is the density relation between the cold and warm columns of water defined. This power must overcome the friction of the water against the tube, cooling effect of the walls, changes in direction, contraction, and like factors of resistance opposed to the circulation. The value of these factors may be ascertained accurately and in such a manner that they may be brought into definite relation with one another and a positive circulation established, so that the details of a thermosyphon system may easily be planned ahead. These being known, a typical example may be constructed. Fig. 2 is a graphic representation of such a cooling system.

Some Theoretical Considerations—*M* indicates the motor, *L* the return tube, *K* the radiator and *m m* the center or dividing lines of the hot and cold zones of the motor and radiator, *b* representing the vertical distance between the two. It follows then that:

W volume warm water delivered.
d inside diameter of *L*.
t_1 temperature of outgoing water.
t_2 temperature of returning water.
γ_1 density of outgoing water
γ_2 density of returning water.
g acceleration of the drop $= 9.81$ m/sec.
l length of the tube *L*, in meters.
ρ coefficient of friction.
ξ coefficient of resistance.
v speed of the circulation.

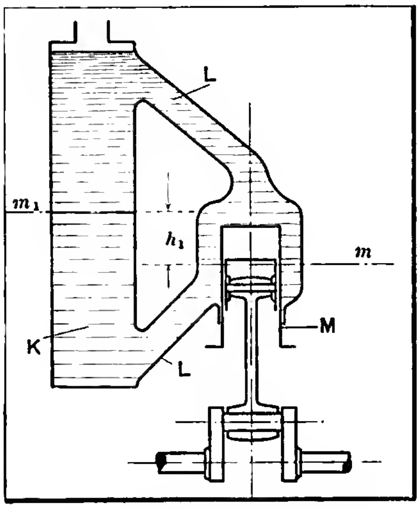

Fig. 2—Typical example of thermosyphon cooling system

The equation for *W* is then as follows: (Rietschel, *Sanitary Heating*, 1891; Birlo, do., 1891).

$$(1) \qquad W = \frac{d^2\pi}{4} \times v \frac{\gamma_1 - \gamma_2}{2} (t_1 - t_2) \times 1000 \times 3600.$$

While the number of heat units per hour and the speed of circulation necessary are derived from the following formula:

$$(2) \qquad v = \frac{W}{10000} \times \frac{1}{275.65\, d^2 (t_1 - t_2)} \text{ m/sec.}$$

*Translation from the German of "Der Allgemeine Automobil Zeitung," by Charles B. Hayward.

W is known in each case, but d and v must be taken for the master formula (3) which will give the attainable speed of flow.

$$(3) \quad h_1(\gamma_2 - \gamma_1) \geqq \frac{v^2}{2g} \times \frac{\gamma_1 + \gamma_2}{2} \times \left(l \times \frac{\rho}{d} \Sigma (\xi) \right).$$

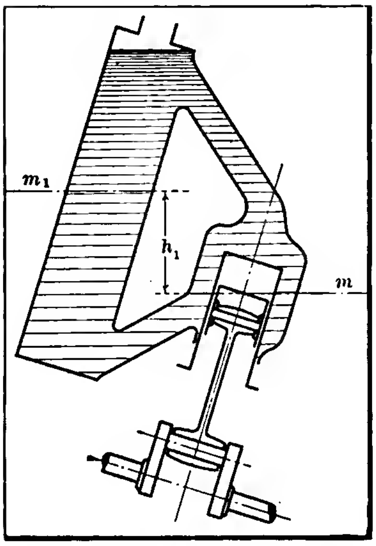

Fig. 3—Showing inclination of thermosyphon system mounting a 20 per cent. grade

This formula will be found to produce substantially different results, so that the operation should be repeated, taking a different value for d. In no case should the product of the right member exceed that of the left.

Coefficients of Resistance the Same as Air.—The coefficients of resistance are approximately those established for the movement of air, the principal ones with which we are concerned in the present case being as follows (Rietschel's *Manual,* 1894):

1. Increase of section $\quad 1 - \left(\frac{f}{c^2 f_1}\right)^2$

2. Decrease of section (obstruction) $\quad \left(\frac{f}{c^2 f_1}\right) - 1$

3. Contraction, inlet of same diameter $\quad$ 1.0 (c = 0.85)

4. Contraction, with enlarged inlet $\quad$ 0.5 — ~ 0.2 (c = 0.90)

5. Right-angle bend, sharp corners $\quad$ 1.5

6. 135-degree angle $\quad$ 0.6

7. Right-angle bend, rounded $\quad$ 1.0

c = linear contraction coefficient.

f = cross-section of tube.

The friction coefficient is, according to Weisbach:

$$(4) \qquad \rho = 0.01439 - \frac{0.0094711}{\sqrt{v}}$$

and the volume and degree of density of the water in a temperature range from 0 to 100 deg. C. is as follows:

Temperature C	Volume	Weight Kilos	Temperature C	Volume	Weight Kilos
0	1.000117	0.99988	50	1.01196	0.98818
4	1.000000	1.00000	55	1.01434	0.98587
5	1.000008	0.99999	60	1.01692	0.98336
10	1.000264	0.99974	65	1.01961	0.98077
15	1.000852	0.99915	70	1.02263	0.97787
20	1.001741	0.99826	75	1.02572	0.97492
25	1.002897	0.99711	80	1.02891	0.97190
30	1.004300	0.99572	85	1.03222	0.96879
35	1.00582	0.99421	90	1.03571	0.96552
40	1.00771	0.99235	95	1.03933	0.96216
45	1.00981	0.99029	100	1.04312	0.95867

It may seem that this method of calculation is somewhat rambling and lengthy, but it is, however, the shortest way of solving the problem. It would be more complicated if the amount of cooling surface necessary for various pipes were taken. Then it would be necessary to outline a formula for the maximum speed of flow in each different conductor. Thus:

$$(5) \qquad \frac{\gamma^2 - \gamma^1}{\frac{\gamma^1 + \gamma^2}{2}} = a,$$

and the formula for any particular stretch of conductor n, would be as follows:

$$(6) \quad a \times h_1 = \frac{v_n^2}{2g}\left(l_n \frac{\rho}{d} + (\Sigma \xi) \right) + \frac{v_{n1}^2}{2g}\left(l_{n1} \frac{\rho}{d} + (\Sigma \xi) \right) \text{ etc.}$$

For a predetermined temperature drop and cross-section of conductor, we may obtain constants from formula No. 2, which will serve to greatly simplify the calculations.

What Influence the Height *H* Has—The importance of the factor h_1, representing the vertical distance between the center lines of cold and warm zones, is very evident in the different formulæ. Were this equal to zero, or even negative, a circulation would naturally be out of the question, and the higher the cool body of water is placed over the hot, the greater will be the driving force, and, in consequence, the speed of the circulation. But the vertical distance h_1, separating the two levels, as it appears in Fig. 2, can hardly be accepted as a fixed relation, particularly where the conditions were not favorable. It must not be forgotten that we are not dealing with a stationary installation, and that even in traveling over good roads, the rising and falling would be such that the relation of the two would be continually changing, now above and again below.

Assume, for instance, that the automobile of which the cooling system illustrated by Fig. 2 forms a part, is mounting a 20 per cent. grade, which gives us Fig. 3, and in which it will be evident that the relation has been altered in such a manner as to make it much more favorable for rapid circulation of the cooling water. The distance h_1 has been increased substantially and with it the driving power of the circulation. This is a prominent and peculiar characteristic of the thermosyphon system that makes it particularly advantageous for automobile work, for the motor runs much hotter in hill-climbing and the intensity of the water circulation is increased to correspond. Naturally, the relation taken in the foregoing formulæ is that which obtains in ordinary running and is based on the minimum amount of cooling necessary under such circumstances.

Form of Cooling Used by Leading French Firms—Another example of this type of cooling system is shown in Fig. 4, which illustrates its arrangement as applied to the Renault cars, on which the radiator is placed behind the motor in order to obtain a relation between the hot and cold levels that will insure a strong circulation. It will be evident that here also the unfavorable conditions brought about in hill-climbing have been taken into consideration. In view of the insignificant amount of driving power available, it is marvelous that even a minimum speed of flow should be produced. To put this on a basis where its regulation will be absolutely certain and always bear a constant relation to the working of the motor, the complete temperature range should be worked out. For a system with a total height of 0.3 meter for h_1, and a temperature drop of from 90 to 40 deg. C., the driving power is obtainable from the following:

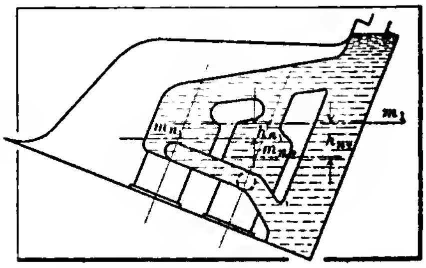

Fig. 4—Form of cooling system used in leading French cars, notably the Renault

$$(7) \quad \text{Total: } a \times h_1 = \frac{0.99235 - 0.96552}{\left(\frac{0.96552 + 0.99235}{2}\right)} \times 0.30 = 0.00725 \text{ m.}$$

So that under unfavorable conditions, such as mountain climbing, as shown by Fig. 3, there would be a head corresponding to the pressure of a water column of 7.25 mm.

Careful attention should be devoted to the laying out of the conductors—the greater the diameter, the less the resistance and, consequently, the greater the speed of flow. It is seldom possible to make the latter exceed .03 meter per second, even with conductors of large diameter, for if the change naturally took place more rapidly and the difference in density were eliminated, the temperature drop would be insignificant.

Another Point of Vital Importance.—There still remains an item of importance to be taken into consideration; an excessive amount of space must not be allowed between the sections or tubes of the radiator. While the friction will be insignificant where tubes of literal cross-section are adopted, as recommended, on the other hand, it must also be considered that the heat-conductivity of water is slight (0.51 according to H. F. Weber) and that if the interior arrangement is not such as to insure a quick and steady movement, light counter-currents will be set up with detrimental results to the cooling.

Consideration should therefore be given to the question as to which of the two most essential cooling appliances is the most suitable, in order that it may be definitely determined. In general, however, it may be maintained that from the standpoint of efficiency and simplicity, it is difficult to render definite and decisive judgment as to the superiority of either the thermosyphon, or the pump circulation system of cooling, except insofar as the omission of the pump makes a logical conclusion inevitable. Then there is the greater certainty of operation, the far simpler arrangement, and the decreased danger of freezing to be mentioned. It will be apparent from the foregoing that for the thermosyphon system, as opposed to pump circulation, all radiators are not well adapted, so that the latter has an advantage and that is the slight temperature drop.

Provided that the pump exerts a strong and constant suction, the average temperature of the water will be considerably higher, owing to the increased speed. It follows, therefore, that there is a greater delivery of heat per unit of surface, and this is an advantage in which the thermosyphon is lacking. For the same thermal efficiency, the radiator employed with the thermosyphon system must also be larger. How much larger still remains to be definitely determined. Only the investigations of Péclet give any data on this point. However, there exist authentic data on the coefficients of heat dissipation for arbitrary speeds of flow of the cooling fluid under such conditions, although the automobile industry does not appear to have taken advantage of this information as yet. We have simply established the rule according to which the speed of heat-dissipation through a wall is governed, and that the resistance of a body of water to undergo a drop in temperature is inversely proportional to the strength of its movement. Investigations are now being carried on with a view to the further development of the thermosyphon system of cooling, and particularly as a means of trying to overcome the disadvantages mentioned above, but the present status of the experimental work does not permit of publication of the results, as yet. The thermosyphon system is largely in the minority, so far as its present use is concerned, but it is certain that its application will ultimately be general and then the causes referred to will have been overcome.

A STORY OF THRIFT AND AN AUTOMOBILE

By H. L. W.

LESS than fifteen years ago two very young people in a mid-Western State were married. Their possessions were a sewing machine, a few yards of new rag carpet, a few dishes, a little bedding and a few pieces of old furniture. They had little or no money.

The first few months were spent on a farm as tenants where they had a house, rent free, and a garden plot and could keep a few chickens. Both were frugal and had no bad habits, and added a little to their goods. Then the man took a position at $40 per month as clerk for a grocery firm in X——, a town of 8,000 or more population.

The wife did all her own house-work and sewing. Having a good eye for a bargain, and quick to see the possibilities of remnants, she dressed on almost nothing. She was also a good cook. In the fruit season her husband on Saturday nights obtained, for very little, fruit that the firm would not risk keeping over Sunday. This she put up for winter, thus securing enough for their use at a merely nominal cost. A baby came before the end of their first year, adding to their expenses.

After a year or two with this grocery firm the man found a similar position in a larger town. This store did a big business and he soon became in fact, if not in name, manager, though his salary attained only $60. The close confinement affected his health and after a year or two he returned to X——, where he obtained a position as traveling salesman for a wholesale grocery house. He speedily rose to be one of its few best salesmen. His wife still did most of her work and sewing, although the children now numbered two.

While working for this firm he invested his savings in a lot and built a house, borrowing from a building and loan association. This debt was discharged rapidly and they were the proud possessors of a comfortable modern house with a fine lot.

Manufacturers, to push their goods, offer premiums (of cash sometimes, but more frequently of silverware, articles of furniture, etc.) to the salesman traveling for houses buying from them. The man did so well that their house was largely furnished by his premiums, among them being one or two musical instruments and a phonograph. In this way in time he secured two or three phonographs with nickel-in-the-slot attachments. These he put up in railroad stations on his route, paying, of course, a percentage for the privilege. These machines, each, brought in several dollars monthly.

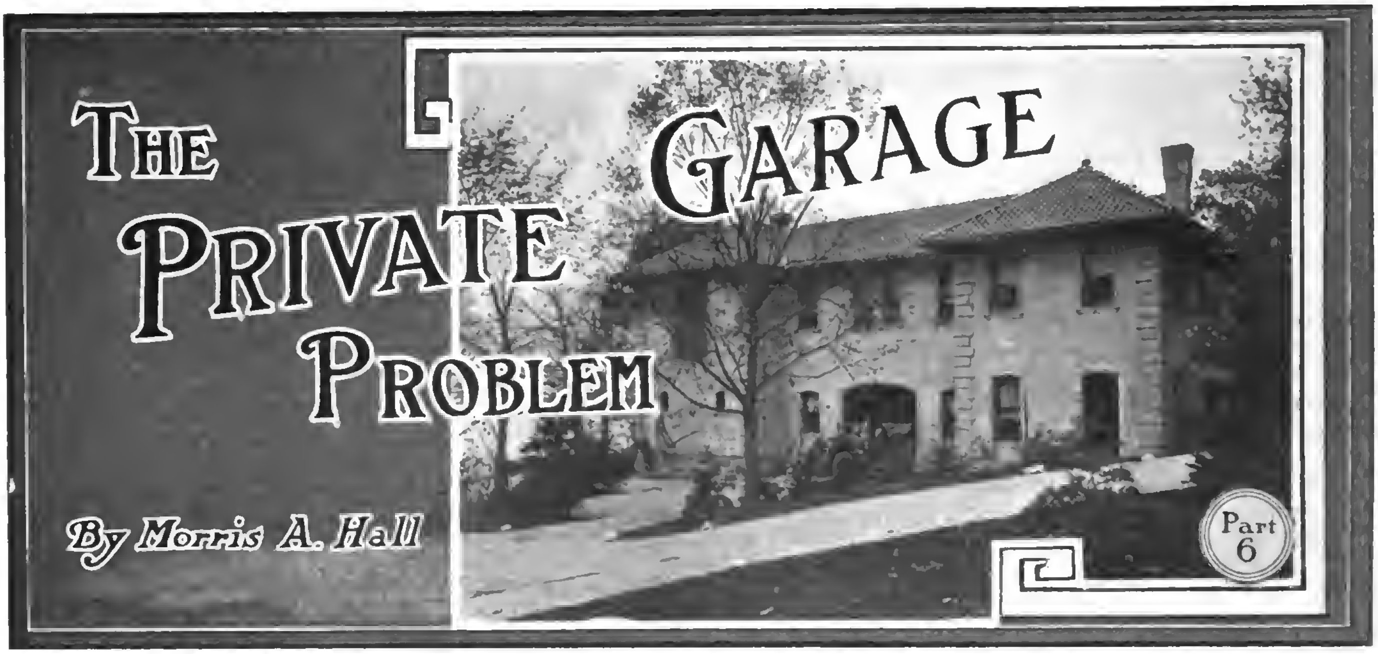
In time his house proposed to give him a certain sum in cash yearly in place of settling his expense account. He took the offer, bought an automobile, using it as far as possible to make his trips, and nearly paid for it with what it saved for him the first year. There were, of course, some places that he still had to make by train all the time, and others that had to be reached thus when roads or weather made the automobile impossible.

He had an inherited bent for mechanics and was soon selling automobiles as a side line, his wife attending to this business for him in his absence. This trade grew rapidly till the machines came in by the car load. They were sold on commission, which was clear profit, as they were delivered on arrival, and so no expense for store-room was incurred.

Convinced there was more money in the automobile business than in groceries, he resigned his position and removed to a town farther west. Here he started a garage and repair shop, and bought and sold machines. He now owns considerable real estate and is sole owner of his business. On an invested capital of $10,000 he recently cleared in one year $9,000 above all expenses, including living.

His wife has been of great assistance, keeping books for him and running the business in his frequent absences. To do this, she has employed a competent housekeeper, wisely considering her time worth more in the office than in doing housework. This does not mean that the home or the children have been neglected Two better behaved children it would be hard to find. Nor does it mean a total sacrifice of self. She has found time to study and take lessons in subjects which her limited advantages in girlhood prevented her acquiring before marriage.

These young people—neither is yet forty—have not denied their children or themselves reasonable pleasures. In later years they have traveled considerably. But from the first, they have kept well within their income and have watched for opportuni- which no one can justly say is not rightfully theirs.



Large Ornamental Cement Private Garage and Stable at Yonkers, Overlooking the Beautiful Hudson River

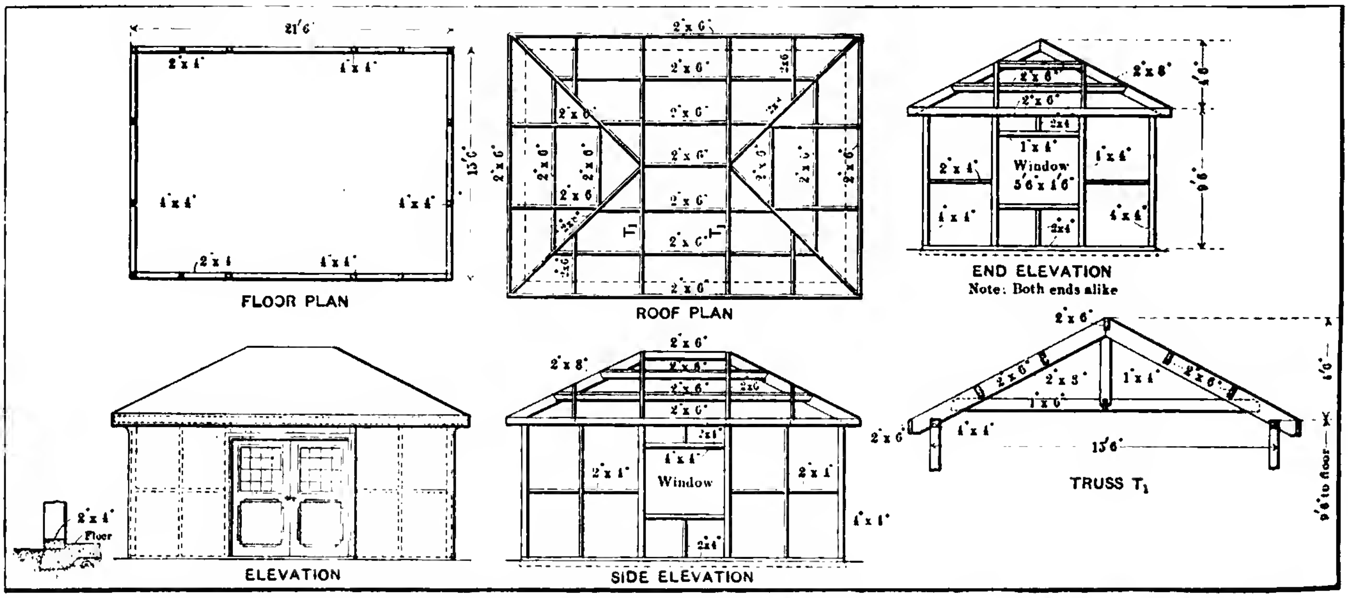
CONTINUING our concrete and cement story from last week, a number of garages of larger size will be given. In these, while no attempt has been made to produce great architectural beauty, the designs and actual work of construction show considerably more scope and, therefore, require somewhat different treatment from those previously given.

While the small house built by the man of modest means and for that reason, very simple, is by far the most interesting, the larger buildings represent more thought and may not be as lightly dismissed. For one thing, the larger sizes mean longer walls, and larger unsupported walls and roofs. This necessitates considerably heavier iron for the reinforcing and more of it, when the reinforced form of concrete is used. And when it is not used, this means much heavier walls; that is, walls of a much greater thickness. The reinforced form, too, will have greater thicknesses of concrete.

In the larger sizes, the roof design is easily the biggest problem, for it is desirable to have an unobstructed floor—that is, without posts. Now the bending moment at the middle, the point of greatest strain, varies as the linear width, but as the cube of the thickness of the supporting member. So if the width is doubled, the thickness is multiplied by 9. This would lead to some unusual thicknesses, so that the strength is increased by more internal reinforcement, rather than simply increasing the thickness of the material.

Another problem enters as soon as the number of cars to be housed passes one, and that is the matter of maneuvering space. With a single car, the shifting around may be done outside and the movement within restricted to a simple in and out motion. With two cars, this same thing does not hold, for there will be the pit, cutting into the available floor space. This, too, must be considered in such a situation as: one car properly placed, and another coming in, with a necessity for the use of the pit. In that way, the two-car garage must allow for about three cars: that is, space for each of the cars and additional space large enough to allow either one to go to the pit without disturbing the other or moving it.

Larger Number of Cars Introduces More Difficulties—With additional cars this trouble becomes even more pronounced, thus with three cars there must be room for each one, plus sufficient space to allow any one of the three to go to the pit and return to its place without disturbing either of the others. This would



Complete Plans of Commodious, Medium-Sized, One-Car Garage to Be Built in Concrete on Metal Lath figure out to about floor space for five cars. This argument does not apply, however, to the public garage, since there every inch of space must be utilized at times, while at other times there is room for many more cars than are in the place. The writer has seen a dozen moved to bring one to the pit, this sounding like waste labor. It is, but labor is sometimes cheaper than space.

At the head of this article is to be noticed an excellent example of the private garage. This is not only a model garage, but, considered from an esthetic standpoint, has what many garages, even very large ones located on big estates, lack, namely, some architectural adornment. This garage shows, too, very plainly the tendency of the wealthy man not to tie himself up to any one method of transportation, provision being made under the one roof both for several large touring cars and runabouts, as well as several fine horses. This division of space really makes the building a combination barn-garage, but the features of building construction most suitable to the automobile are also very necessary to the up-to-date stable.

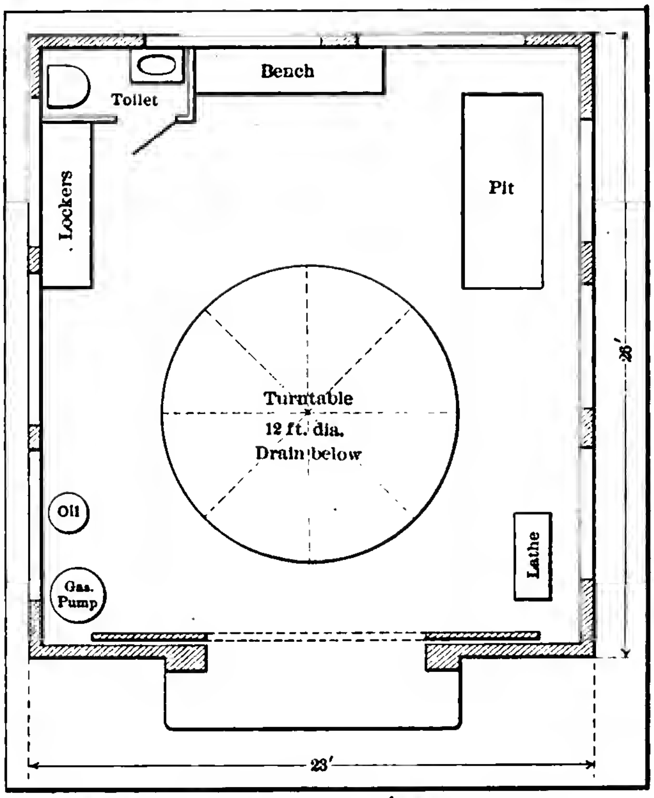
It might be mentioned in passing that this garage is located at Yonkers, but a few miles north of the New York City line on the direct road into the city. The owner, Rudolph Oesler, has several cars, a big Benz seven-passenger touring car and a runabout. The building is really in two parts, the lower for the cars and horses; the upper, living rooms for the coachman-chauffeur and his family. The convenience of the latter has been considered in more ways than one. Thus, the back side of the building, the one opposite to that shown, carries on the second floor level, a very large roomy porch, roofed over against inclement weather. On this, the employees may spend many a pleasant hour sitting in the shade (this being on the north side) and overlooking the Hudson River at their left and the main road north and south between New York and Albany at the right-hand side.

Like the building itself, the floors are of concrete, with a wash rack occupying the center of the large floor space. The projection on the right houses the harness-room and the door shown leads into the oil and gasoline storage-room. The whole left wing nearest the Hudson, which may be dimly seen in the distance, is given over to the horses. The automobiles, on the other hand, have the whole central portion and the back part of the right wing, behind the oil and harness-rooms. This gives an ell-shaped space about 25 feet by 30 feet long dimensions.

Another One-Car Cement Garage Plan—Before finishing up the story of cement in its relations to the small concrete garage, it will be advantageous to give another set of plans from which the amateur owner may, if he wishes, construct his own motor house. These are given on the previous page and show a more ornamental job than the one previously given for a single car. The shape is more nearly square, greater space being left along what would be the back side for closets, shelves and cupboards.

Being intended, like the other, for the use of concrete or cement plaster over a metal-lath, Hy-Rib or some other similar product, the walls are of wooden beams; mostly 2 by 4 and 4 by 4's. The roof, on the other hand—it runs up to a point, different from the others—is framed up in 2 by 6 and 2 by 8 timber, with a few cross-beams of 1 by 6 and verticals of 1 by 4.

Provision is made for three large windows, one in each end and one in the middle of the back opposite to the large, double sliding or hinged doors. As the floor plan shows, the space allowed for the car is very liberal, being 15 feet by 21 feet inside. This garage, like the previous small one, is intended, was designed, in fact, for the use of cement, and in order to use wood, corrugated iron, sheet steel, or other sheeting on the outside in place



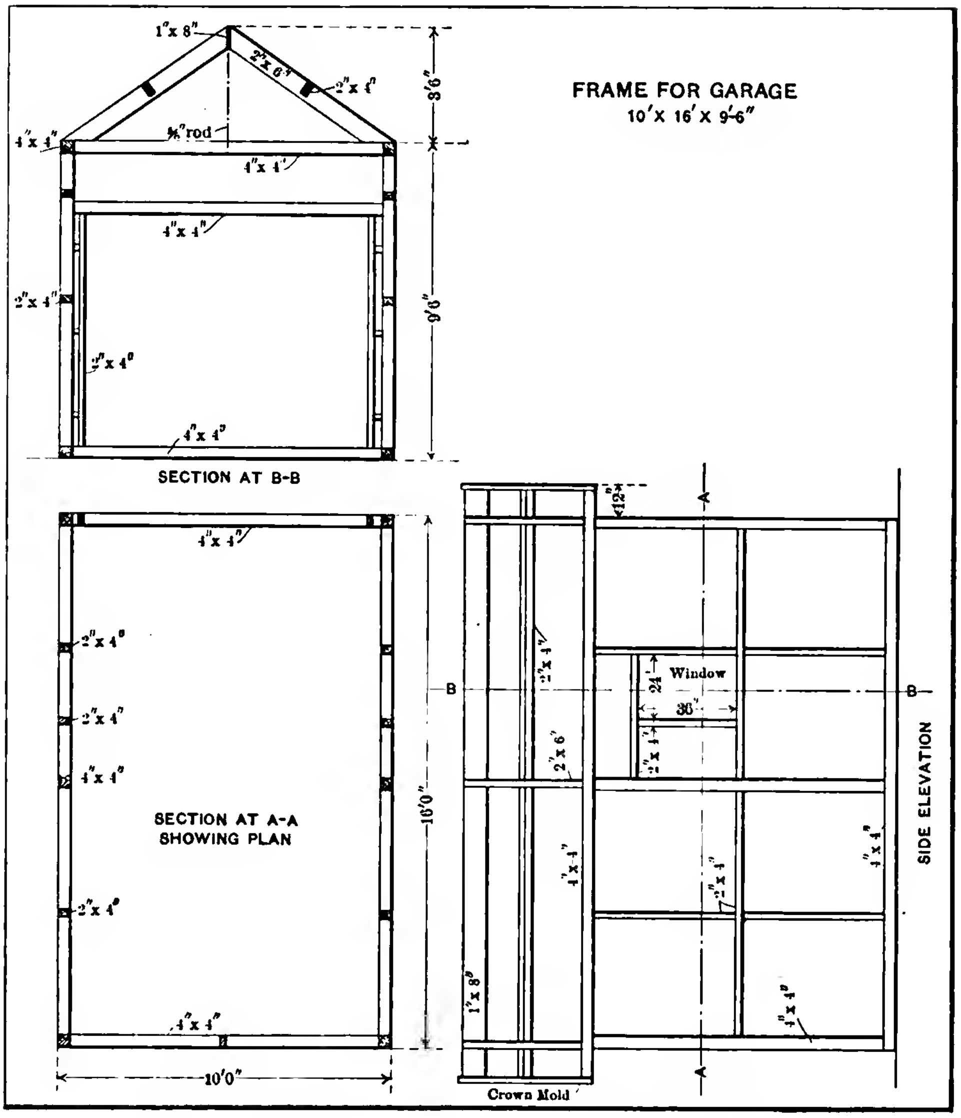
Suggestion for Large and Well-Equipped Garage

of cement, would require some small alternations. The bill of material and estimate of cost on this house, using the wooden framework shown and cement, as described, is as follows:

Bill of Material and Estimate—One-Car Garage

Frame—Sides,	4 x 4, 229 lin. ft.	
	2 x 4, 169 lin. ft.	
Roof,	2 x 6, 228 lin. ft.	
	2 x 8, 40 lin. ft.	
	1 x 6, 46 lin. ft.	
	1 x 4, 8 lin. ft.	
	Total, 726 sq. ft., at $20.00 per M..............	$14.52
	Cut and waste (15 per cent.)...................	2.18
	Labor, at $40.00 per M.........................	29.04
	Hardware, etc.	2.50
	Windows, double hinged, in place (estimated at $6.00 each).............................	18.00
	Doors (double, 8 x 8) in place.................	20.00
Walls,	612 sq.ft. No. 28 galv. Hy-Rib painted.	
	570 sq. ft. plastering, 1¾ in. thick.	
Roof,	475 sq. ft. No. 26 galv. Hy-Rib painted.	
	475 sq. ft. concreting, 1¼ in., and plastering underneath.	
	Water proofing at 3 cents per sq. ft............	14.25
	Making the total cost without Hy-Rib or cement	$100.49

Cement Garage and Stable of the Noted Horseman, C. K. G. Billings



Another Cement-Plastered One-Car Design, But Slightly Smaller

the owner of Lou Dillon, 1:58 1-2, the holder of many world's records, and of numerous other fast horses, to have a very large garage. But, as a matter of fact, his large combined stable-garage, located at Fort Tyron, One Hundred and Ninety-sixth street and Fort Washington road, New York City, as shown at the bottom of the preceding page, not only has not given over all of its spacious interior to the horses, but nearly one-half of the building is devoted to automobiles, the list of six or seven machines owned including all of the world's most famous makes.

This building forms an excellent example of what may be done in a very large building with concrete, being at the same time a most excellent design from the utility point of view and a very nice appearing place architecturally, although it probably would not be designated as beautiful.

Elsewhere is shown another plan for a small garage in cement of the same type and general description as the one for which the bill of material has just been given. Lack of space prevents giving the same for this structure, but it may be summarized. The total estimated cost, with lumber at $25 per thousand, and labor at $3.50 per day, exclusive of the same two items as before, is $79.30, which, adding twice as much for the omitted items, would make the whole cost about $240. The economy of reducing the floor space by 54 per cent is thus summed up in actual dollars, although this design is somewhat less elaborate, which doubtless had some little influence upon the total estimated cost.

Even if the omitted quantities be taken at twice the others, this makes the whole garage come to but $302, which is certainly very cheap for an all-cement garage of this size.

Turntable Really Enlarges Floor Space—As previously discussed, the maneuvering space needed when more than two cars are housed, is very considerable. In this connection the turntable forms a very useful adjunct of the modern large garage, for it economizes on the floor space. That is to say, having a turntable in the center of the floor does not cut out any of the floor space as a pit does. On the other hand, it allows swinging cars around within its own narrow confines and with absolutely no maneuvering other than a straight ahead run onto the turntable and another similar run off of it.

Aside from the big house, where it saves space, and thus first cost, it is of great and daily use in the small well-equipped house, where it saves much work, either of pushing the car by brute strength, or by carrying in fuel, starting a cold engine, and then backing and filling until the required location is obtained. On the previous page is shown a design for a small garage in which this feature is included. The outside width of 23 feet is like the length of 26 feet, ample. Although large, considered in the abstract, it is not any too large when the projected pit, lathe space, oil and gas pump space, lockers, bench, and toilet are all taken into account. Sliding doors are figured upon as economical of space and more handy to open and close than the hinged variety.

Noted Horseman's Big Concrete Garage and Stable—No one would expect as enthusiastic a horseman as C. K. G. Billings,

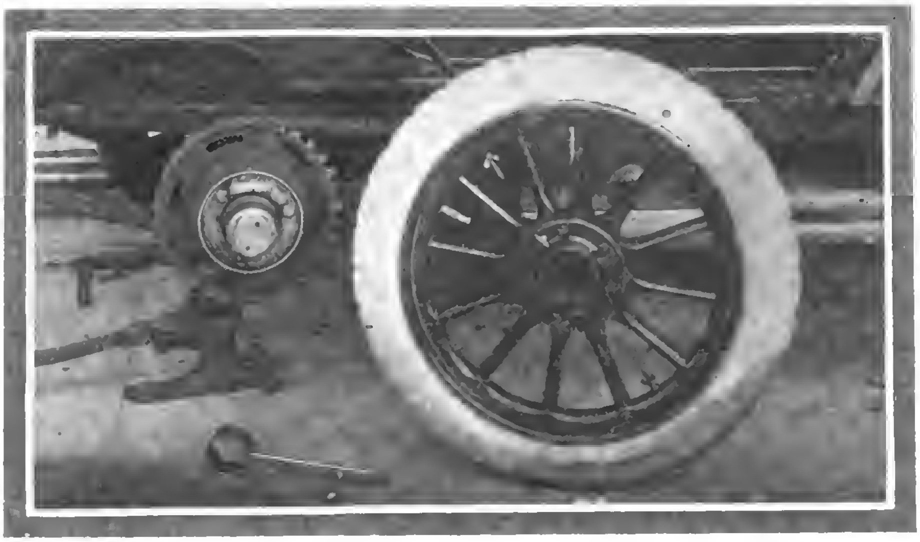
Playing so large a part in modern society, the automobile should be considered in the construction of a house. Then, too, in the general scheme, the advantage of knowing this, locating it, and figuring on it prevents marring an elaborate arrangement as might be done otherwise. On this page are a garage and the corner of a very elaborate residence. This is one of the show places of Long Island, Italian villa style. An ugly garage would spoil it.

(To be continued.)

Garage Built to Complement Fine Concrete Residence

DETACHABLE WHEELS POPULAR IN GREAT BRITAIN

COVENTRY, ENG., Oct. 12—A new detachable wheel possessing special features of merit has just been brought out by the Dunlop Tire Company and will be shown at the Olympia exhibition next month. The special advantage of this design is that any looseness or side play can be taken up immediately by screwing the actuating sleeve further out, whereas with most other types of detachable wheels such looseness cannot be cured once it has been set up. Briefly described, the device works on the simple principle of placing a doubly screwed sleeve between the internal hub, which has a left-hand thread, and the outer hub shell, which has a much coarser left-hand thread. Consequently, when the sleeve is turned in a right-hand direction by means of the spanner, it unscrews somewhat off the inner hub, and this action causes the wheel proper to be screwed up tight against the flange of the inner hub. The wheel is prevented from revolving during this operation by the studs which fit into holes in the inner hub flange.



Showing New Dunlop Detachable Wheel Ready to Place On Hub

The action will be easily understood by reference to the accompanying illustration, the main points being that both the inner and outer threads are left-handed, and that the outer thread is of a very coarse pitch, so that the sleeve need only be unscrewed slightly off the inner hub in order to make the wheel screw fully on the outside of it.

Any locking device is really unnecessary, but to prevent any possibility of the wheels being removed by some unauthorized person with an ordinary spanner, a ratchet and pawl device is fitted in the hub so that the sleeve cannot be turned to unscrew the wheel unless the special spanner is used. This wheel is supplied both in the wire and in the wooden artillery forms.

Wheels of this type have become extremely popular in England, and even the little two-seater is rarely seen on the highways without some device of the sort on its running board or rear body. They are also much used in racing, as it is said that they can be changed even more quickly than the demountable rim, which has its chief popularity on the Continent. The detachable wheel, in fact, is a strictly British development. It was over its use, it will be remembered, that S. F. Edge had his famous quarrel with the French racing commission at the time of the last Grand Prix, which resulted in the withdrawal of the Napier team from the event. The subsequent slaughter of various demountable rims, which put half the cars out of the running, seems to have justified his action. At any rate, the average Englishman firmly believes in his detachable wheel.

(A) Inner hub. (B) Actuating sleeve, screwed on left hand on inner hub (fine thread). (C) Outer hub, screwed with coarse left-hand thread, to engage with sleeve. (D) Driving keys.

MICHIGAN'S AUTO-MAKING STATISTICS

LANSING, MICH., Nov. 22—That there has been a great growth during the present year in the automobile industry in Michigan is shown by the report of the Secretary of State, which shows that from January 1 to November 15, the present year, 34 companies for the manufacture of automobiles were organized in Michigan, representing a capitalization of $15,423,000. The amount of capital stock of the various concerns ranges from $5,000 to $10,000,000, the latter figure being the capital stock of the Packard Company of Detroit. In addition to this 54 companies were organized for the manufacture of automobile parts.

NEW SPEED HONORS FOR THE KISSEL KAR

In the recent Phoenix (Arizona) 50-mile derby, which was run November 12, and in which a new Pacific Coast record was made for the distance, the performance of the Kissel-Kar, a car of medium price, was an unusually meritorious one. This six-cylinder machine was the only competitor of an imported car of three times its price, but upheld the American end in valiant style. The winning Isotta-Fraschini finished in 52:45, which averaged practically 57 miles per hour. Back of this but 28 seconds, the showing of the Wisconsin-built car was gratifying to its friends.

LETTERS INTERESTING

HOW TO BUILD A RACER

Editor THE AUTOMOBILE:

[2,093]—Through the columns of your magazine will you kindly answer the following questions: Is there any concern that makes all of the car ready to run with the exception of engine and transmission; that is, frame, running gear, shaft drive, front and rear axles, steering gear, etc.? I want a car to have a 20 to 25 horsepower engine, with all of the parts strong enough for this purpose, and once read of a concern in this business, but have forgotten the name. I do not refer to the 15 horsepower Metz plan car, as I want a miniature racer.

Middletown, N. Y. SUBSCRIBER.

There are several concerns known to be doing just this kind of a business, although all of them will also sell you the engine and the transmission if you wish. A number of other firms make and sell about all of the parts which would be necessary but do not advertise to sell them assembled as you seem to wish. As to the former, you may try the following firms:

Borbein Auto Company, Ninth street, St. Louis.

Dart Manufacturing Company, Chase street, Anderson, Ind.

Elwell-Parker Electric Company, Cleveland.

Franklin Machine Company, Franklin avenue, Brooklyn.

Neustadt Auto & Supply Company, Olive street, St. Louis.

The third of these, as you will note from the name of the firm, builds chassis ready for an electric power plant, but it is included in the list because the firm would doubtless be able to supply you with a frame which would fill your wants.

In the second class of parts makers manufacturing all of the necessary parts but not assembling them to sell as a whole, a list is also given. It is urged in favor of this method, that, as long as you expect to put in the engine and transmission yourself, you might as well assemble the whole machine and save the cost of that work. In addition, this method will render you more familiar with the component parts and their peculiarities. The list follows:

Auto Parts Mfg. Co., Muncie, Ind.

Continental Engine Company, S. Canal street, Chicago.

Elyria Machine Parts Company, Elyria, Ohio.

Garford Company, Elyria, O.

General Mfg. Co., Richmond street, Elkhart, Ind.

High Wheel Auto Parts Company, Muncie, Ind.

Indiana Auto Parts Company, Marion, Ind.

Long Arm System Company, Cleveland.

McCue Company, Hartford, Conn.

A. O. Smith Company, Clinton street, Milwaukee, Wis.

From this list you should be able to get a firm which will be able to fit you up with all of the required parts. In buying these parts, if, as you say, you want a sort of racer or very fast car, you must bear in mind that racing or fast driving sets up many unusual strains, and you should select your parts accordingly. That is, either the running gear should be of a superior material or else you should buy for a higher power than you expect to install, in order to have an increased factor of safety. Thus to buy for 35 horsepower would be right.

CAR WON'T RUN SLOW

Editor THE AUTOMOBILE:

[2,094]—Please advise me what to do to make my car run at a low rate of speed on high gear. A knock or miss develops unless the car is speeded up to ten or twelve miles an hour. At a higher rate of speed, or on a pull, it seems to work perfectly. Changing the gasoline feed does not remedy the matter, since in either case the car has to run at a rather high rate of speed before the engine works smoothly.

I have difficulty in starting the motor by cranking, either with rich or thin mixtures without first priming carbureter.

Weatherford, Tex. A. N. GRANT.

Most carbureters have two adjustments, one on the needle valve or regular air inlet, and the other on the auxiliary air. The two work more or less in combination, and the proper combination is often difficult to find. You say you have adjusted the gasoline; have you tried the auxiliary air? Another possible cause is that the magnets of your magneto have lost their strength. This may have been caused by taking the magneto apart and failing to put proper "keepers" across the magnets while the armature was absent from its place between the poles, or their weakness may be due to natural depreciation. This would in a measure account for difficulty in starting the motor; we do not believe the priming or absence of it enters into the question, as on many cars this is necessary even under the best circumstances.

Remagnetization is a delicate process, and should not be attempted rashly; so the only way of telling whether this surmise is correct would be to try a new magneto. If there are other cars of the same make in your vicinity, you might try a temporary exchange of magnetos, which would at once show whether or not the trouble lay there.

LIKES OUR STYLE

Editor THE AUTOMOBILE:

[2,095]—I have taken great pleasure from time to time in looking over "Letters Interesting, Answered and Discussed." More than that, I think them of great value, especially to the person who drives his own car. So I can say that I was greatly surprised that any one would have the nerve to kick as in letter 2,073 of the Nov. 4 issue. This party must have been out on a tour with a friend, who wanted to know the name of every passing car. Being unable to make good, he kicks; either that or else he is trying to revert this section to advertising. What automobile owners want to know is what causes certain troubles and how to remove or prevent them. I wish to enter a protest against such kicks. H. P. F.

Chicago, Ill.

A HOME-MADE MACHINE

Editor THE AUTOMOBILE:

[2,096]—Will you please give me some information about a car which I made myself from parts of different machines. It has a 12-horsepower opposed motor, planetary transmission, and chain drive with nine teeth on front sprocket and 31 on the rear. The engine runs well without load and fairly well on level ground, but doesn't seem to run fast enough in high gear to develop any power, or enough to pull up a five per cent. grade without changing to low. I have a new Schebler carbureter, and the engine has fairly good compression. The machine weighs about 1,000 pounds. What can I do to make my car pull better? I am not anxious to go fast, but just to get it to pull up a small grade without changing to low gear.

Fernandina, Fla. W. F. M.

The obvious thing for you to do is to gear the machine lower. Nine teeth is rather few for a sprocket, so we suggest that you make the rear sprocket larger, instead of the front one smaller. Some cars of the same type use rear sprockets up to 40 teeth. If you put on a 39-tooth sprocket the speed of the machine would be reduced about one-fourth, and the pulling power on hills greatly increased.

The larger sprocket may, however, interfere with the design of your rear axle, if this is of the single-chain, central-drive type. For such possibilities the makers of these axles, in the stock sizes, provide curved bolts instead of the straight ones which straddle the sprocket and hold the two halves of the casing together. In case your axle is of this type, and the larger sprocket would interfere, you can obtain these curved bolts from the maker, or have them forged by a local blacksmith, and save the expense of a new one.

By the way, did you ever have your machine weighed on trustworthy scales? Most machines of this type weigh nearer 2,000 than 1,000 pounds. If you have not had the machine weighed, try it, and we think that you will find your 12-horsepower engine is doing pretty well after all.

This is really the vital consideration, for even with high power, if the weight be increased in proportion, there is no gain, and the extra weight must be driven at the expense of additional fuel. Less weight per horsepower means not only less fuel used, but in the matter of speed, the power is then more effective. On page 314 of the Aug. 19 issue, you will find this subject discussed very thoroughly, with a series of figures given for the different classes of machines, taking the divisions by price from the lowest up to the $5,000 cars. Your car would apparently come in a class which had an average power of 19.5, an average weight of 1,280 pounds, and an average ratio of power to weight of 65.6 pounds per horsepower. If your power and weight are right, the ratio of 83 is not bad.

HOT WATER HELPS SOME

Editor THE AUTOMOBILE:

[2,097]—Will you please give me the name and address of a firm or of firms making a two-cylinder engine suitable for an Oldsmobile curved dash runabout, one that would go into the old machine without much trouble. I notice that some of the latest engines have a device for letting the hot water from the engine jackets into the carbureter, this giving more power and speed on heavy pulls. Do you know of any automobile companies that have this device on their cars? ELDON C. FRIE.
Duncan, Okla.

As to the two-cylinder engine, nearly any opposed engine of this type would be suitable, and by consulting the advertising pages of THE AUTOMOBILE you will find that a number of firms making engines are advertised there. We do not know of any firm making an engine especially for this use.

In the matter of water jacketing the carbureter so that the hot water from the engine jackets may be used with beneficial effect of the action of the carbureter in cool weather, this is done by nearly every reputable carbureter manufacturer. This is usually fitted as an option, that is, the carbureter maker makes the same sized carbureter with the jacket and without. The purchaser has his choice, the charge for the jacketed form being but little more than the other.

After buying a carbureter so equipped, any handy mechanic can fit it to your car. All that is needed is several lengths of small diameter copper or brass tubing. A hole is bored into the water outlet over the cylinder head and another elsewhere in the water circulation system at any convenient place. Into these holes are fitted and soldered the tubes. It is then an easy matter to apply the tubes. When applied, the hot water rising from the cylinders when heated flows into the carbureter jackets, around and through them, out, and back into the water system again.

"EATS UP SPARK-PLUGS"

Editor THE AUTOMOBILE:

[2,098]—Could you please tell me why the first cylinder of a new Model T Ford "eats up" spark plugs? A new plug will run about one day of continuous running and is then seemingly "all in," even after cleaning it. The car is new and the cylinder seems perfectly clean. RUSSELL R. HOLMES.
Whiting, Ia.

The answer to letter No. 2,100 above seems to fit your case pretty well, too, although your letter opens up several different possibilities. Your statement that the cylinder seems perfectly clean and that the plugs refuse to work after an experience in this cylinder, even after being cleaned, suggests that the trouble may come from another source, namely, overheating. This overheating, of course, could be purely local and not otherwise affect the running of the engine. In fact, the construction of your engine suggests a way in which this might occur.

The cylinders are cast in one block, with the heads separate in another block. The cooling water passes from the cylinder block to the head block through a number of holes in the upper face of one and the lower face of the other, which register when the two are brought together. If the hole nearest the spark-plug of the first cylinder should become stopped up, the circulation might be impeded to the extent of allowing that part of the cylinder to become extremely hot. This heat would crack the porcelain of the spark-plug.

This is a deduction rather after the manner of Sherlock Holmes, and we are by no means sure that it is correct. An examination of your engine, by removing the cylinder head block, would quickly show, and in any case can do no harm.

GARAGE WINTER HEATING

Editor THE AUTOMOBILE:

[2,099]—Will you please advise me as to whether a heating plant should be installed in a small garage housing one car, in order to maintain the car in good condition after being put up for the winter. It has been suggested to me that unless an even temperature was kept the varnish and paint would crack and at the same time considerable rust would accumulate. An article in "The Automobile" concerning preparing the car for storage through the winter would be timely. XX.
Gambier, O.

We do not believe that such precautions as you describe would be necessary; certainly we can recall no acquaintance who ever went to similar trouble and expense, nor can we recall anyone whose car seemed to suffer from neglect to provide heating. If the varnish and paint are of suitable quality they should not be affected by any degree of cold to be found in these latitudes. As for rust, that can be cared for at the time of putting the car away. The motor, gears and driving mechanism should be thoroughly cleaned out and provided wtih fresh oil, and all parts which might be attacked by rust should be coated with pure grease or vaseline. We agree with you that an article on putting a car up for the winter would be timely, and it is by no means improbable that you will find one in an early issue.

In fact, it is not unlikely that one of the concluding chapters of the garage story now running, "The Private Garage Problem," will contain much matter on the subject of heating of automobile houses.

IGNITION "SPARK GAP"

Editor THE AUTOMOBILE:

[2,100]—Will you kindly, through "Letters Interesting" or otherwise, help me out of the following dilemma? I have a four-cylinder water-cooled automobile, and have been having trouble with the ignition in No. 1 (front) cylinder. This cylinder has spells of refusing to fire, and no amount of coaxing will induce it to do so as long as the high-tension wire is attached to the spark-plug. If the high-tension terminal is detached from the spark-plug and held about 1-8 inch away, letting the spark jump from the terminal to the plug, the cylinder will immediately begin to fire, and continue as long as the terminal is held in that position. I have used new plugs and new batteries, but with the same result. W. A. ERVIN.
Petersburg, W. Va.

Several years ago a number of spark-plugs were made with terminals designed to afford a second gap for the spark to jump, in just the way you describe. The object of this was to give a better spark inside the cylinder. For electrical reasons which are none too clear, this exterior spark causes a spark to appear at the regular sparking points when the latter are so sooted up that they refuse to show a spark otherwise. This may be explained by saying that the electric current, coming first to the outer gap, is banked up there until it is strong enough to jump across; and then it comes down on the second gap with a rush and goes across by its own momentum, as it were. The spark-plugs embodying this feature gradually dropped out of sight, as improvements in spark-plug construction and in motor lubrication made them, for the most part, unnecessary.

The first cylinder of your motor probably has some peculiarity which is very hard on spark-plugs, so that even new ones last but a short time. Although you do not say so, we believe that you have found that a new plug will work all right in the "hoodoo" cylinder for a short time. If this is true our conclusion is undoubtedly correct. The trouble may be due to the lubrication, some fault of motor construction causing the first cylinder to receive more than its share of oil. If your lubrication is by a force-feed oiler, feeding each cylinder separately, the remedy is to try cutting down the supply to the first cylinder. If the lubrication, on the other hand, is by splash to the cylinders, the trouble may be with the partitions in the crankcase, maintaining a higher level of oil in the first pit than in the others, or to an extra nut or other protruding part on the connecting rod big-end, which would cause it to throw up more oil. If the motor has one of the modern circulating systems of lubrication, the overflow hole from the pit into the pump well may be stopped up.

If you don't care to tamper with the lubrication system, why not make yourself a plug with a permanent exterior "spark gap?" You might fasten the terminal to the plug with a strip of fiber or other non-conducting material in such a way as to maintain the proper gap. Or, if you do not care to do this, there are spark plugs made which have a testing arrangement, which includes a gap of this kind. One of these should answer all of your requirements.

Fig. 1—Development of Schebler carbureter, beginning in 1900, and ending with semi-automatic type of 1909

ACCESSORIES of necessity, as they relate to automobiles, differ from accessories in general in that the cars will not render good, if any service, without them. A radiator, for illustration, seems to be necessary to a water-cooled motor; a carbureter, likewise, is a necessity to every motor. A gradeometer, on the other hand, is not absolutely necessary; the car may be utilized in the absence of this device, although, as a convenience, such an instrument may have a fitting value.

In drawing the distinction, it is done for the purpose of pointing out the trend, not from guesswork, but as it seems to be reflected. Accessories of convenience will probably always be made in separate shops, simply because makers of automobiles will most likely have all they can do to turn out cars.

The more progressive of the specialists, feeling that they are in a position to compete with the world both in point of quality and price, keep adding to their buildings and improving their processes and, in all truth, the strides now being made are past describing. Obviously, the cost of an improvement, while it may foot up to many thousands of dollars in the abstract, amounts to very little per unit when the output is on an enormous scale, and the accessory makers are in a position to take advantage of this phase of the situation to the maximum extent, and this is one of the reasons for believing that they are with us to stay, and that they offer one of the solutions to the great problem involved.

A Concrete Example Will Best Show—Any further discussion of this phase of the automobile situation, along the lines taken, would be a mere reiteration; the history of the accessory makers' growth, however, may be reflected by writing the history of some one capable manufacturer, and while the story will be told from one angle only, even so, it will be in its most simple form and leave more for the telling from some other point of view at a later time. Disregarding the fact, then, that there are many other plants which would serve perfectly to illustrate the permanence of the accessory-making industry, the one nearest at hand will be taken, and since the writer is at Indianapolis, it is but a short ride to the plant of Wheeler and Schebler, makers of the Schebler carbureter.

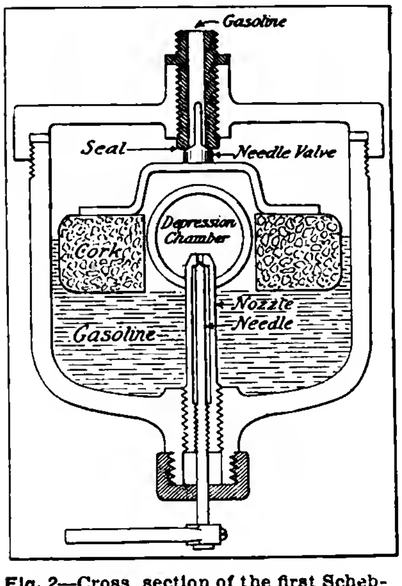

Fig. 2—Cross section of the first Schebler carbureter, made in 1900

Referring to Fig. 1 (A) depicts the first carbureter made by George M. Schebler, in 1900, before he engaged in business with Frank H. Wheeler. The firm of Wheeler & Schebler was formed as the result of the good performance of the first carbureter, and the business acumen of Wheeler has been proven by the growth of the concern. The second carbureter, (B) Fig. 1, was brought out in 1901, differing from the 1900 type in some minor particulars. The point to be here made, however, lies in a certain similarity of all the Schebler carbureters from A to J, inclusive.

Fig. 2 is a section of the 1900 type of carbureter, and the concentric float, somewhat modified to be sure, is still used. The first carbureter, in the light of present practice, was a crude device, but Schebler, than a violin maker of note, aimed to build a satisfactory carbureter for a motor he then built, having failed to find one on the market such as would perform in a satisfactory manner. The carbureter offered as B, Fig. 1, was made in 1901 and it differs from the earlier type in that the float was improved and a bale attached to diametrically opposite sides engaged a lever, which, in turn, imparted motion to the needle-valve, thus controlling the flow of gasoline, after a fashion, more certain. Fig. 3 is a section of the 1901 type of carbureter.

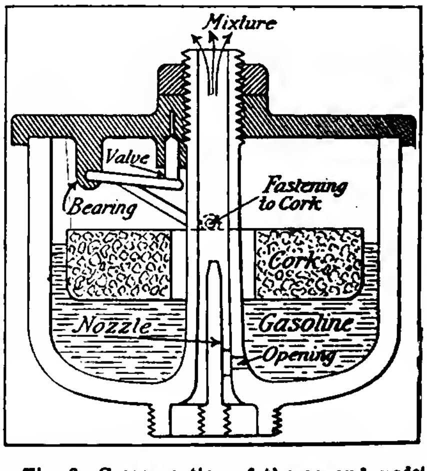

Fig. 3—Cross section of the second model Schebler carbureter made in 1901, which has been little changed

In 1902 the carbureter shown as (C) Fig. 1 was brought out and letters patent were granted on the type. In 1904 some detail changes were made, as shown by (D) Fig. 1, and the business end of the industry took on a more promising turn. In 1905 the carbureter looked as at (E), Fig. 1, a section of which is given in (A), Fig. 4, and in 1906 more refinements brought the carbureter up to (F), Fig. 1, and in section as depicted in (B), Fig. 4. Model E came out in 1907, looking like (G), Fig. 1, and the section was as given in (C), Fig. 4.

Water-jacketing Was Introduced—By this time, owing to changes in the quality of gasoline, it was found that, under some conditions of service, water-jacketing offered advantages and

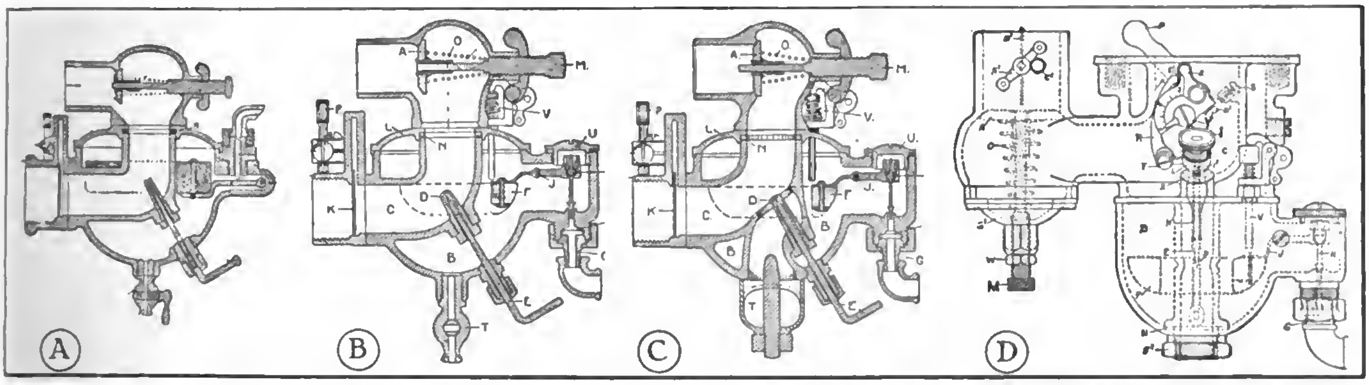

Fig. 4—Sections of Schebler carbureters as made from year to year, showing a certain similarity in design, style and finish

the Model F Schebler carbureter was offered to buyers. The exterior of this carbureter looked as in (H), Fig. 1, shown in section in (C), Fig. 4. The following year the company brought out an improved form of motorcycle carbureter, which has been continued, subject to all possible improvement down to the present. This carbureter is depicted in (I), Fig. 1, and (J), Fig. 1, is of the 1909 Model L carbureter, a section of which is offered in Fig. 5, with names of parts given.

Constant Refinement Price of Success—But one year (the second) was passed without bringing out a new model or making refinements of a character designed to improve the good working qualities of the carbureter. Had there been any disposition to avoid the cost of new models, it is avowed that changes would have been less frequent, but, as may be quickly determined by a little calculating, the cost per carbureter, of changing, is scarcely worth taking into account, excepting that it would be fatal to make a mistake.

By sticking to the main idea, confining the advances to a mere evolution, and refining as proof of better results would be the reward, the maker was enabled to advance the situation from year to year without risking a serious mistake, and as a reward for stability of design and manufacture as well as enterprise, the business grew in a fashion which may best be illustrated by a table showing the number of carbureters made and shipped:

CARBURETERS DELIVERED SINCE 1906.

Year.	Carbureters Shipped.	Carbureters Made.
1907	37,263	48,625
1908	49,876	57,513
1909	100,000	100,000
1910 (estimate)	200,000	200,000

The above tabulation tells a story of the marvelous growth of the motor accessory business, and also of the faith of one man in it; in 1907, when business in other lines looked bad, this concern went right on building carbureters, and actually did build 11,362 carbureters more than were sold, and there were times during the year when the stock in hand was even as high as 25,000 carbureters.

Present Situation Looms Up Big—A single maker of cars is now taking a car load per month (about 5,000 carbureters) from this one plant alone, and the foundry is using raw material on a basis as follows:

Copper................................2 car loads per month.
Tin......................................6 tons per month.
Lead.....................................2 tons per month.
Spelter..................................1 ton per month.
Home scrap...............................all made.

In this plant every part of the work is done, starting in the

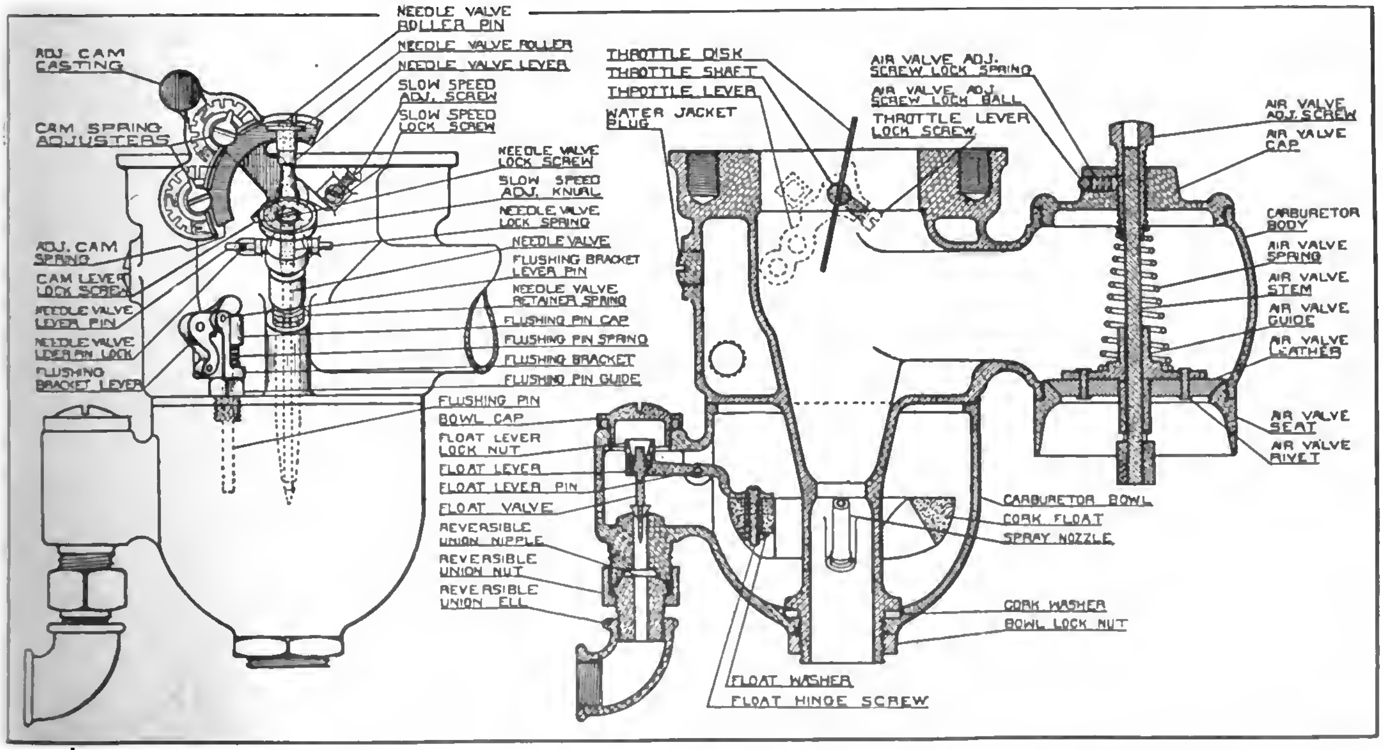

Fig. 5—Section of the present model of Schebler carbureter, showing strangle type, auxiliary air valve, and adjustments

foundry, and ending with the final test before shipping. In order to appreciate the enormity of the undertaking, it will be necessary to follow through the plant and beginning with the raw material for the charge, in the foundry, as shown in Fig. 6, of copper ingots, it is but a step to the crucible and other furnaces. The illustration shows but a part of the battery of crucibles, and allowing from 60 to 80 pounds per charge for each crucible and five heats per day, counting the tilting furnace in the foreground, the capacity of the foundry is not far from the amount as shown above for the raw material purchased for the foundry during a recent period of one month. Gas is used for firing, for the most part, and the change to gas entirely, is rapidly being made.

In another part of the foundry cores are moulded, and Fig. 8 represents a core-oven, for baking them, of which there are two, side by side, and in addition to this provision the cores are heat dried in a room for the purpose. Some of the castings make their own cores and when this part of the work is ahead, the moulding is done partly by machine, one of which is shown in Fig. 9, while moulding in general is done on the floor as depicted in Fig. 10. The character of the work is under the control of the maker of the carbureter in this case, and experience has shown that it pays to use "new brass," thereby reducing "wasters" and the number of parts that are found wanting during inspection.

Much to Be Said for the Machining Process—A certain similarity exists between the big carbureter used to furnish producer gas to the gas engines and the output of the plant. The gas producer illustrated in Fig. 11, made by the Smith Gas Power Co., of Lexington, Ohio, is charged with pea coal twice each day and about one-half of a ton of this coal per day serves for the purpose. The fuel is burned in the generator G in the presence of atmospheric air and steam in definite proportions. The combustion of some of the coal which takes place due to the action of the blast, liberates heat, and under the influence of this heat, in the presence of excess carbon, the steam carried over is decomposed, contributing its oxygen for the carrying on of the combustion and liberating hydrogen as a desirable constituent of the resultant fuel gas. The combustion of the carbon in the presence of oxygen liberates heat and the decomposition of steam, under a suitably high temperature, in the presence of carbon, absorbs heat. To

Fig. 19 Testing bench showing a double row of carbureters being tested for tightness and buoyancy of the float

obtain the desired quality of fuel gas, then, it is necessary to regulate the temperature, and this is done by properly proportioning the amount of air and steam by means of the regulator.

Fig. 12 depicts a 100-horsepower, three-cylinder Rathburn gas engine. Provision is now being made to greatly increase the size of the power plant, it being the idea to displace some of the smaller (horizontal) gas engines with new type of 250-horsepower vertical engines.

What Happens Beyond the Power Plant—The carbureters, after they come from the foundry, are chipped, slicked off on grinders, and then they are subjected to the action of a sand blast as depicted in Fig. 13. This process leaves the carbureters free from core sand, and of an even surface all over. The product thus prepared is ready for machining operations and Fig. 14 is illustrative of the use to which special jigs are put in holding the work under a drill and assuring interchangeability of work. The jig G, despite the irregular shape of the carbureter, holds the work firmly, and it is but the task of a moment to set the same and begin drilling.

Fig. 15 is still another illustration of the way jigs are contrived to displace the irregular task which would follow were the workmen required to lay out the work and center the same for drilling. Fig. 16 differs from the preceding figures in that a special jig, or, in this case, chucking device, takes the part and fixes it in the correct relation for turning operations. The turret tool, of which a suitable number are at hand, does quick and accurate machining and is largely responsible for the even quality of the product.

In view of the presence, in carbureters, of a considerable number of small parts, it is found necessary to employ automatic screw machines to a considerable extent or put up with the ills of a famine market, and be short of material, more often than not. Fig. 17 depicts a corner in the automatic screw machine department with an Acme automatic screw machine (side view) in the foreground. These machines are devoted to the production of such parts in the carbureters as screws, nozzles, bolts, nuts, etc., made from bars of steel, hard brass, or other material, such as will best serve the ends. The automatic chucks of the screw machines, while they demand the use of materials, as bars coming close to size, are capable of accommodating themselves to quite some extent, although it is commercially possible to limit variations in diameter to 0.0005 inch above and below nominal diameter. Fig. 18 is a general view of the battery of automatic screw machines, and it is of more than a little interest, first, as showing the extent to which carbureters require the use of costly automatic tools if they (the carbureters) are to be produced in quantity, on a basis of interchangeability, and again, the compact plan of installing the tools will be of interest to those who may have to cope with just such problems.

Testing Is Done During the Process—When all the parts required are in sufficient quantity ahead, considering any given model, the work of assembling a lot is undertaken, and inspection is necessary, at every stage, in order to assure that the carbureters will pass the final test, one phase of which is shown in Fig. 19. In this case a considerable number of carbureters are set up in rows and each one is filled with gasoline to note if the metal is porous or if the joints leak. If the material is satisfactory and if the joints are all ground tight, the float is then adjusted in such a way that the gasoline will stand in the nozzle within 3-16 inch of the top.

Some Special Features for This Year—Referring to Fig. 5, it will be observed that the leather seat of tbe air valve is reinforced by a metal flange behind it. Time has proven that certain grades of leather will serve well for this purpose, but it has also been shown that the leather will curl up unless it is thus supported. True, the amount of the deformation is but slight, but it is just enough to unbalance the mixture and motorists are not always in fettle to cope with the ills which are natural to an unbalanced mixture.

The float, which is made of Spanish cork, is of the finest possible grade, so close, in fact, that it would absorb but little gasoline, even if submerged for months. In order, however, to safeguard the cork, it is subjected to a coating process which precludes the chance of float trouble. In the first operation, in the process of coating, a fine grade of shellac is cut up in grain alcohol, and when it is in a perfectly liquid state, and thin, the cork is submerged. When the time has been sufficient to allow the thin shellac to penetrate all the pores and form a skin all over, the cork floats are then removed and subjected to a drying process for sufficient time to assure that the shellac in the pores, as well as on the surfaces, is dry and hard. A second dipping is then given the cork; the shellac being more viscous but in even condition, and when this layer is dry and hard, if the cork, after being submerged in gasoline, shows the required degree of buoyancy, it is accepted.

The float lever pin (see Fig. 5) is not midway between the center of the float and the axis of the float valve; the lever advantage is in favor of the float, and the result is that the valve seats firmly. The conical seat of the valve is easily ground to tightness, and the valve stem is of a fine grade of material, and light. Inertia, therefore, will not have a mal influence, and the float, being submerged in gasoline, considering the lightness of cork, will not set up motion when a car is negotiating bad roads, so that the flow of gasoline, to the bowl, is always carefully regulated and flooding is entirely avoided.

The sectional drawing, as reproduced in Fig. 5, presents ample evidence of an adequate thickness of walls, but what is more to the point is the perfectly even casting work, with all cores so nicely set that an uneven thickness of walls at any point is avoided. New brass, that is, brass made from ingot copper, tin, lead and spelter, with just enough home scrap to fetch up the teeming mass, accounts for the even quality of the castings, but the foundryman, since he has a plant fitted out for this especial work and confines all efforts to products of this character, is enabled to train a corps of moulders up to a high state of efficiency. It is equally an advantage to do all the work of every character, considering the question of the delivery of carbureters, for in these days, with a material famine well in sight, makers of automobiles will naturally feel confident when it is made plain to them that every situation is under control in the one plant and the raw material is corded up in the storehouse, there to be taken out and melted up as required.

What the Near Future Holds Forth—The power plant is being increased by 250 horsepower, which includes a new and larger gas producer as well as a 250-horsepower gas engine. The foundry will be increased to double its present capacity, and the floor space present and near future is estimated as follows:

Present plant, including foundry............	150,000	square feet.
New addition, not including foundry........	51,750	" "
New addition to foundry..................	8,000	" "
Total floor space after addition is made....	209,750	" "

All buildings are of a substantial character, brick and reinforced concrete, and the new addition, which will take up about a half a block just back of the present plant, will presently be under way; a church for negroes, and one or two private dwellings, now on the ground, having delayed matters somewhat.

Everywhere in the plant provision is made to cope with fire, and sanitary arrangements, as well as other conveniences for the workmen, makes the plant one that is far from labor trouble of any character, so that, deliveries are made with great certainty and the company is frequently in a position to fill an order for five or ten thousand carbureters the day the order is received.

RAMBLER REGULARITY AT KENOSHA

Kenosha, Wis., Nov. 22—Work on the new Rambler models is advancing with such exactness as to put deliveries in the same class as the Twentieh Century Limited, and The Automobile's representative in going over the plant finds many evidences of methods that make for precision of fit of parts, so that, in assembling, delays will scarcely have to be coped with. The situation all along the line is for interchange ability of parts, and this very desirable condition is a prime issue in the production of Rambler cars under the direction of Thomas B. Jeffery & Company.

The company, in order that its large stock of repair parts will be a real accommodation to its patrons, keeps an exact record of everything shipped, and the system of duplication of parts in vogue at the plant, makes it worth while to do so. The new laboratory, which is now sufficiently complete to be of the greatest service, is on such a large scale that it almost outstrips the name. A new 500-horsepower generator set, directly connected with a Corliss engine, will soon be in operation, and present additions to the Jeffery concrete construction, saw-tooth buildings will bring the aggregate up to 20 acres of floor space.

Additions to the building number five, amounting to over 1,600 square feet, which makes room for the new laboratory.

TARRYTOWN BECOMING MAXWELLVILLE

Tarrytown, N. Y., Nov. 22—Tarrytown is gradually becoming Maxwellized. To keep abreast with the enormous demand for 1909 models the company is compelled to acquire all available factory space in the immediate locality regardless of cost. The newest acquisition, that of the Tarrytown Tile Works factory, provides 62,520 square feet, and though only recently acquired is in full operation. Again, the new brass foundry on the company's property with 21,500 square feet is just completed, soon to be followed by the new aluminum castings plant with twice the area. The company now controls six plants, and with the completion of those now in process of erection will employ nearly 6,700 employees.

SUCCESS OF THE FISK FREE AIR IDEA

Some time ago the Fisk Rubber Company conceived the idea of furnishing its branch houses with compressed-air tanks, which are placed on the sidewalk close to the curb, for the convenience of passing automobilists. On opening the tank box, a rubber tube is disclosed, to be attached to the tire valve, and a lever and gauge regulate the amount of air. Keys to these boxes are furnished to automobilists on request.

WHAT THE ACCESSORY PHASE OF THE INDUSTRY REPRESENTS

WE frequently hear the fixed phrase "parts makers" and it is sometimes said that they are not imbued with the idea of doing accurate work beyond the barest necessity. Then, there are the class of persons who confuse parts makers with accessory manufacturers. They fail to discriminate as between the makers of complete units and members of units; as if, indeed, there is no difference as between a piston for a cylinder of a motor and a carbureter or a radiator. Certainly, there is a vast difference, and it is self-evident that there is far less chance of trouble due to the purchase and use of a carbureter than can follow when a crankshaft, for illustration, is made in one shop, the cylinders in another, and the remaining parts somewhere else; all to be assembled by the final maker of the car.

F. H. Wheeler

Besides, there is a further distinction to be made; accessories of convenience, catering to luxury, can never occupy the position which is natural to an accessory of necessity. Having made this distinction, rather with the expectation that it will convey the impression that necessities must be taken in all seriousness, it is a natural sequence that accuracy is the child of the work done in the production of a necessity.

Obviously, a thing made by a specialist, if it is a serious undertaking, will be far more likely to thrive than when it is given the slight care which is all that can be expected from even a corps of designers who have to cope with the intricacies of 900 different genera of parts which will be found in a full-fledged automobile.

But there is still another phase of the problem to be given at least scant attention; makers of automobiles, even if they build a large number of cars, cannot expect to rival the manufacturers of necessary accessories who cater to numerous car producers. While it is true that cars are made in thousands in some instances, it is equally a fact that manufacturers of necessary accessories foot up on their order books in hundreds of thousands.

When units are made in hundreds of thousands, the cost of special tools, fixtures, jigs, and equipment falls to a level so low that the overhead charges per unit may be even in fractions of a mill. The cost, therefore, of a set of tools such as will guarantee absolute accuracy is no bar, and the result is that the accessories made on this tremendous scale, under fitting conditions, are so accurate that there is no further chance for improvement.

Having arrived on the plateau of accuracy in the manufacture of accessories, brought about as a natural evolution in the process involving quality, it remains for accessory manufacturers to hold their own, which is a matter of providing for the future by anticipating the wants of customers, which is not an easy task to cope with, owing to the rapid growth of the industry.

In estimating on the future, basing prognostications on the past year, it has thus far been impossible to be conservative and to be anywhere near right. The wildest imaginable figures seem to be still more wild when they are exceeded, as they invariably are, and yet it is a serious matter to fail to come up to the requirements in the production of accessories, so that success, in its broadest aspect, will come to the class of accessory manufacturers who build right, think big, and prepare to receive business on a basis of a half million automobiles per annum, and that, too, in the near future.

F. H. Wheeler

RELATION OF ACCESSORY MAKERS TO CAR BUILDERS

IN the manufacture of accessories for automobiles there are several terms to be coped with, brought about, to a vast extent, by relations which producers of accessories bear to makers of cars. The accessories, as carbureters, radiators, etc., are made in sizes, and it is not always possible to select the size of carbureters, for illustration, such as will be a perfect fit. The difficulty is brought about by a lack of co-operation of makers of motors and of carbureters. As the state of the art will permit, considering the designs made, it is better to carefully consider the sizes of motors and select the proper carbureter in every case, for then the carbureter, instead of having to cope with the bad relations due to the poor selection, will respond more perfectly under severe conditions and will afford a more pronounced degree of flexibility under conditions of changing speed.

Geo. M. Schebler

The torque of a motor may be relatively high at some one speed, due to the perfection in design of the motor itself, but it will not be on a basis of constant torque at all speeds, unless the carbureter is free from dead points and capable of delivering a mixture of a constant richness at all speeds. It is evident, as before stated, as present in carbureters of advanced designs, but to realize it to the maximum involves the deliberate consideration of the size of the motor when selecting the carbureter. If the carbureter is of the exact right form from every point of view its universal properties will then be there to influence the torque of the motor instead of being absorbed in the process of bringing up the average working conditions in the presence of defects of selection. Under these more perfect conditions the high torque due to motor harmony will be maintained at all speeds and the service rendered will involve flexibility to the maximum possible extent.

In practice, when the carbureter reaches the ultimate user there are one or two points which can well be reduced to formula. If a motor fails to perform in a satisfactory manner it is a fallacy to at once assume that the carbureter is out of order. It is more chance that the ignition system is in need of a little attention or that the compression in some one or more of the cylinders is down. The first recourse, then, is to be sure that the ignition is in good working order and properly timed, and then observe if the compression is in proper presence in the respective cylinders. Even so, it is necessary to see if there is any more gasoline in the tank, and since gasoline is loaded with foreign matter, it is not difficult to understand how such matter may impede the action of the more delicate parts of the carbureter. The natural inference is that the carbureter should be examined with a view of cleaning it out, if necessary, before making adjustments. The final operation, under the circumstances, is to adjust the carbureter if necessary, and then only.

In view of the conditions in point of design and the respective makes of carbureters nothing can be said in a general way which will serve as a guide in the process. Even so, it is extremely important to approach satisfaction with the utmost care and to avoid upsetting the good adjustment which may obtain, only to find that the trouble is somewhere else.

EUROPE'S DISILLUSIONMENT

Europe's automobile industry has had a sad awakening. Just at present it is undergoing a more or less painful adaptation to new conditions, which but few of the constructors had the wisdom to foresee.

The trouble really began two or three years ago. A body of large and world-famous manufacturers had been pursuing their majestic course, building four and six-cylinder cars of forty horsepower and more. Their cars, from the engineering point of view, were very creditable productions. Suddenly these manufacturers discovered that there was no longer a demand for their cars. Intent only on a visionary ideal, they lost touch with their public.

The market for large cars is necessarily limited, and even more limited in Europe than in America. The market suddenly filled up, and the annual production was about ten times the amount necessary to keep it full. About the same time several European governments got the idea that automobiles were a good subject for increased taxation. Result: no Grand Prix, no Paris show, no Berlin show; also a hasty renewal of interest in the popular-priced car.

Then the big and famous makers discovered further that it was not sufficient merely to announce a popular model in order to bring to their feet this profitable class of trade. A number of firms whom the famous makers had been accustomed to look down on superciliously had formed a solid and thriving patronage, and were by no means disposed to relinquish it. Moreover, the buyers of medium-priced cars, far from being dazzled by a name, required good and sufficient proof of superiority before signing their checks.

After the first shock of disillusionment, most of the big makers took their lessons manfully. They realized that they must give their best, both in designing and in workmanship. The supreme efforts of their talented designers, of their well-equipped machine shops and corps of skilled workmen were required to win a place in this new aristocracy of the industry.

It was to be expected that the small cars turned out by such factories would have a neatness and refinement in detail often lacking in the output of a cruder plant; yet the latter had the advantage of long experience in that class of work, and excelled through sheer strength and solidity. Between these two camps the struggle has been keen. In the striving for advantage much more attention than usual has been paid to new ideas in construction, such as slide and rotary valves. The value of such competition to the industry cannot possibly be overestimated.

For this reason the Olympia Show—held solely because the association promoting it is composed of popular-priced makers—includes within its walls the finest exhibit ever before seen of "the cars of the future." The forty-horsepower model (foreign rating) has been somewhat relegated to the background; the salesmen speak of it reluctantly, unwilling to admit that it has been continued. The day of the "forty" is well-nigh past; the day of the "fifteen" is just dawning.

AS TO INTERNATIONAL RACING

It is among the possibilities that international automobile racing may have a fairly active renewal innings next year, especially if the congress adopts the recommendations of the Manufacturers' Contest Association as proposed through the American club which has a sitting in the international organization.

But the indications are that international racing of the old and popular sort has come to its conclusion; firstly, because the foreign makers figure so slightly in the American market, and, secondly, because they have found it unprofitable to continue big competitive events in Europe to keep alive the home market.

The foreigners, as a whole, are turning their attention to aviation and its spectacular contests, simply through a widespread belief that the value of automobile road contests, to them, has depreciated far below par. Hence little may be expected from the American recommendations in the forthcoming meeting in December, though the effort to obtain well-defined international conditions for stock-car racing is praiseworthy, and indicates plainly that the Americans now have no hesitancy whatever in engaging with their foreign competitors in any kind of a contest.

Time was when any American race of importance had a field overwhelmingly foreign in complexion, but it is now a certainty that the excellently managed and contested Savannah Grand Prize race was the finale in real international competition, either here or abroad. Of course, there will be races where both American and foreign cars will participate, and these shall serve, in some degree at least, to diversify competition.

AUTODOM'S HUB SUPPLIES A LIVE NEWS BUDGET

DETROIT, Nov. 23—By far the largest project of its nature with which Detroit has had to do in recent years, and which promises to eclipse anything else of its kind locally in magnitude, is about to be consummated, according to reports from official sources.

The deal involves the establishment in Detroit of headquarters by the General Motors Company, and the installation here of a group of plants of hitherto unequaled size and capacity. Options on sixty acres of land have been secured, and more property is being acquired as rapidly as possible, although to date the operations have been carefully kept under cover. It is understood that the investment in real estate alone will exceed $300,000, and that the contemplated plant when completed will furnish employment to 5,000 men. The details of the project have not been worked out to a point where much can be said authoritatively, but it is understood that the Detroit plant will be devoted largely to the manufacture of parts, as well as turning out complete cars. Unless something unforeseen occurs to block the undertaking, ground will shortly be broken, and it is the intention to have a major portion of the plant in operation for 1910.

Concentration of General Motors in Detroit

Ever since the General Motors Company was organized and began buying up plants throughout Michigan dissatisfaction was expressed by President W. C. Durant and his associates over the vast amount of territory over which their holdings were scattered, and the even more serious drawback of being to a considerable extent dependent upon outside interests for much of their material. This, coupled with the announcement that orders booked for next year will tax every plant of the General Motors Company to its utmost, and that Mr. Durant predicts 1911 will be an even greater year, is believed to be the controlling factor in the decision which will give Detroit another enormous plant, and materially strengthen the proud position it now holds as the hub of the automobile industry of the world. When the Buick Auto Company something like a year ago rented one of the most expensive business blocks on Woodward avenue, in the choicest part of the retail district, and converted it into a salesroom, leaving the other three floors idle, wise ones figured that the company planed moving its head offices from Flint to this city. Whether the building will now be occupied by the head offices of the General Motors Company, of which the Buick is now a part, cannot be determined at this time, although there are rumors to that effect.

Owen Motor Company Developments

Meanwhile, other interests are active, and the incorporation of automobile companies goes merrily on, with many others in prospect.

The new company foreshadowed in THE AUTOMOBILE two months ago, when Angus Smith resigned as secretary-treasurer of the Olds Motor Works, and Ralph R. Owen gave up his position as factory manager of the same concern, came into existence with the incorporation of the Owen Motor Car Company, with a capital stock of $500,000. The principal stockholders of the Owen Motor Car Company are R. R. Owen, Angus Smith and Frank E. Robson. The company has already secured options on a desirable site in Detroit, and it is the intention to begin the erection of a plant at once.

A Rumor Also Involves Lozier

A report going the rounds, and generally accepted as accurate by those identified with the automobile industry, is to the effect that the Lozier Motor Company, of Plattsburg, N. Y., will shortly establish a branch factory in Detroit, to cost $800,000. Several local capitalists of prominence are reported as backing the undertaking. It is said to be the intention to produce a car selling around $3,000.

Newcomers That Are Partially Heralded

Detroit and Pittsburg capitalists have taken options on thirty-two acres of land in Wyandotte, just at the edge of the city, and are said to be contemplating building two large plants, one for the manufacture of machine parts only and the other to turn out complete cars.

President DuCharme, of a Hornellsville, N. Y., auto company, is also negotiating with Wyandotte land holders with a view to establishing a factory there, which he declares would furnish employment to several hundred men.

The Watt Motor Company, capitalized at $100,000, has just been incorporated, and promises several surprises once it gets under way. Automobiles and marine engines will be manufactured on a large scale, the feature of the motor being that it can be reversed without the use of air compressors, according to the designer. Starting, stopping and reversing is all controlled by a single lever, and although the motor is of a six-cylinder type any number of these can be cut out at any time without moving from the driver's seat, leaving any desired number in operation. It is expected the new car will be on the streets early in January.

All of which is not so bad a showing for one week even in Detroit, where big things in the automobile world are of such frequent occurrence that they no longer arouse surprise.

Factories That Are Working Day and Night

In addition to the new companies entering the local field. those already established continue to branch out at a surprising rate, builders working day and night in an effort to keep up with the demands for more space. With no less than a half dozen additions now under way, the Studebaker E.-M.-F. Company has taken out permits for a two-story brick factory 80 x 265 feet, to cost $40,000. In accordance with its long standing policy of not waiting to complete one addition to its enormous plant before beginning another, the Packard Motor Car Company also figures in the week's proceedings with permits for a five-story reinforced concrete structure, 60 x 262 feet, and 72 feet in height, to cost $65,000.

A. L. A. M. HOLDS SPECIAL SESSION

At the A. L. A. M. headquarters, 7 East Forty-second street, its executive committee held a two-day session last week, Thursday and Friday. An announcement had been anticipated, but no information was forthcoming after the meeting. It is understood, however, that something important will be made known in the next fortnight. The impression prevails that W. E. Metzger, formerly of the E-M-F Company, will be successful in making license arrangements for his recently formed company. It is known, however, that he has not consummated arrangements with the Hewitt Motor Company. A definite statement may soon be forthcoming from the Metzger Company.

SYRACUSE CLUB ACTIVE IN SIGN-POSTING

SYRACUSE, N. Y., Nov. 20—Secretary Forman Wilkinson, of the Automobile Club of Syracuse, is still receiving requests from neighboring towns and villages for road signs giving warning to tourists of crossings, bad hills, etc. During the season the club has sent out several hundred signs into various parts of the country hereabout, posting nearly every road leading out of the city for thirty or forty miles, and in some instances much further. As a result of the club's activities, its membership is steadily growing, with indications of a very substantial increase before the Spring driving season opens. The roads in the vicinity have been much improved.

DETAILS OF DETROIT'S NEW WARREN

Detroit, Nov. 22—The Warren Motor Car Company, of which the organization was recently reported, is now insatlled in its plant at the corner of Isabella and Michigan avenues, in this city. The company, which is capitalized at $100,000, is headed by Homer Warren. John G. Bayerline, formerly with the Pope Mfg. Co., and the Olds Motor Works, and more recently with the Hudson Motor Car Company, is vice-president and general manager. R. W. Allen, secretary, is another graduate of the Olds Motor Works and the Hudson Motor Car Company. W. H. Radford is chief engineer. The company will deliver 500 cars before July 1, 1910.

The Warren-Detroit, as the car will be known, will be turned out as a roadster. Its motor has four cylinders, 4 by 4 1-2 inches, cast *en bloc,* with valves on one side. Ignition is by Volta magneto and dry cells. The clutch is a leather-faced cone, and the change-gear selective, giving three speeds forward. Springs are semi-elliptic front and three-quarters rear. The wheelbase is 110 inches and the tires 32 by 3 1-2 front and rear. The car complete will sell for $1,100, and deliveries are expected to begin February 1.

BRIARCLIFF COMMITTEE GETS MONEY

The Briarcliff race committee won back the $4,000 it deposited to guarantee against injury to roads in the Briarcliff race, April, 1908. The money was deposited on the demand of Frederick Skene, then New York State engineer, who threatened otherwise to withhold permission to use the new roads in Westchester County, which were included in the circuit. He agreed to return the money if the roads were not damaged, or to return the balance after making such repairs as were necessary. The committee did not get any money, however, and was forced to bring suit. According to the decision of Supreme Court Justice Platzek, the $4,000 must be returned in full, with interest.

FORD DISQUALIFIED IN TRANSCONTINENTAL

The Contest Committee of the Automobile Club of America has decided that the Ford car No. 2, which had been declared the winner of the New York-Seattle race last summer, was not entitled to the award. The car has been disqualified on account of the substitution of its motor en route. The Shawmut car No. 5 has now been declared the winner.

GENERAL MOTORS ABSORBS ELMORE

Toledo, O., Nov. 22—The General Motors Company now claims as its property the Elmore Automobile Company, located at Clyde, O., the transfer having just been made at a price said to be around the half-million mark. As to the intentions of the new owners, nothing has yet been officially announced, but it is hinted that the factory will be entirely rebuilt, overhauled, and enlarged to such an extent as to make it one of the largest and most important plants owned and operated by the General Motors Company. The location for such an enterprise is said to be ideal, both on account of shipping accommodations, three direct trunk lines running through the city and one electric line, and on account of low taxes and sanitary conditions.

The Elmore Automobile Compay was owned and operated by H. V. Becker and his sons, James and Burton. Twenty years ago the father operated a small stave mill at Elmore, a village near Clyde. About this time bicycles came into the market, and securing an abandoned factory at Clyde, Mr. Becker moved there and started making bicycles. When wheels became a thing of the past, so far as the craze was concerned, the Beckers started manufacturing automobiles, the firm being one of the pioneers in the automobile industry. The factory has been several times remodeled and enlarged.

CANADIAN AUTO SHOW IN TORONTO

Toronto, Can., Nov. 22—The Canadian Automobile Show will be held in the St. Lawrence Arena, Toronto, under the auspices of the Ontario Motor League, from February 24 to March 3, 1910. E. M. Wilcox, secretary of the League, will be the manager. There are some 30,000 square feet of space available in the building. An elaborate plan of decoration will be carried out. The League proposes to have the annual convention of members and others interested in good roads during the week of the show. The session will last three days.

APPERSON WINS LOS ANGELES RACE

Los Angeles, Cal., Nov. 22—The Apperson "Jack Rabbit," driven by Harris Henshaue, won the 150-mile race at Ascot Park to-day in 3 hours 45 minutes. Guy Irvin, who drove a Franklin car, was probably fatally injured when his car went through the fence. R. McIntyre, his mechanic, was hurled from the machine, but not seriously hurt.

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

Dec. 25-Jan. 1....Columbus, O., Automobile Show, Columbus Automobile Club.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel Manager, 1-5 East First South Street.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati, Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Secretary.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 12-19......Syracuse, N. Y., State Armory, Automobile Show. Syracuse Automobile Dealers' Association.

March 21-30......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo Launch Club. D. H. Lewis, Manager, 760 Main Street.

Races, Hill Climbs, Etc.

Dec. 22-29........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

WRIGHTS FORM $1,000,000 AEROPLANE SYNDICATE

SOME of the most prominent capitalists of America, in conjunction with the Wright brothers, have organized a company capitalized at $1,000,000 to manufacture aeroplanes. The incorporation was effected at Albany, N. Y., November 22. The incorporators are Cornelius Vanderbilt, Theodore P. Shonts, Allan A. Ryan, Morton F. Plant, Howard Gould, Andrew Freedman, Robert J. Collier, Edward J. Berwind, August Belmont and Russell A. Alger. The announcement was made by De Lancey Nicoll, of the law firm of Nicoll, Anable, Lindsay and Fuller. The company will be a close corporation.

Either Orville or Wilbur Wright will be president of the company, and the other brother and Clinton R. Peterkin will be vice-presidents. The treasurer and secretary have not yet been chosen. A meeting will be held within the next few days to elect officers. The executive committee will consist of Messrs. Shonts, Freedman, Belmont, Alger and the Wright brothers. The main offices will be opened November 29 in the Day and Night Bank Building, at Forty-fourth street and Fifth avenue, New York.

Statements surprising even to the most sanguine believers in aeroplane have been made by the promoters of the company. According to Mr. Nicoll, the Wrights have for several years purposely refrained from revealing by word or performance the possibilities of their machine, and the public has many surprises ahead when the full powers of the invention are disclosed. Mr. Nicoll is further quoted as saying that the Wrights believe an aeroplane for carrying twenty passengers is perfectly feasible, and that such machines will be constructed by the company in the near future. However, the brothers do not believe that the ocean will be crossed by a heavier-than-air machine until a motor has been invented with a fuel consumption far lower than any made at present. A field will be developed for the aeroplane in the West, for passenger service and carrying the mails.

An aviation field is to be opened during the coming winter in Florida for the instruction of prospective customers, and a staff of instructors will be maintained. It is said that the manufacturing plant will be located at Dayton, O., and that a number of the machines will be delivered by May 1. Those who order machines in advance will be given instruction in Florida during the winter.

The new-formed company will take every possible legal measure to protect the Wright patents, which those of the promoters who have made statements believe are fundamental. One fight which the company has already assumed is the injunction proceeding against Glenn Curtiss, which will come up December 14 before Judge Hazel in Buffalo.

When asked whether, in substance, the syndicate did not amount to a flying machine trust, which would monopolize the manufacture of aeroplanes, Mr. Nicoll replied that the Wrights unquestionably were the owners of all important patents on heavier-than-air machines, and that their claims would be defended by the company against all comers.

BISHOP FAVORS DENVER BALLOON RACE

BOSTON, Nov. 22—The New England Aero Club held a banquet to-night in commemoration of the one hundred and twenty-fifth anniversary of the first balloon ascension. Cortland F. Bishop, president of the Aero Club of America, spoke in favor of his plan for a series of aeronautic contests in different cities of the country, which he believes is the only means of inducing the prominent French aviators to cross the Atlantic. Mr. Bishop urged the New England club to join in promoting one of the series.

Denver is favored by the Aero Club president as the location for the international balloon and aviation meets. The location is especially good for balloons, and new world's records for distance might be made there. Mr. Bishop said that he thought dirigibles were impracticable, and that no provision would be made for them in the meets. Concluding his speech, he offered the New England club a cup as a trophy for long-distance balloon flights, to be competed for during the coming year.

FOR BALTIMORE-WASHINGTON AERO MEET

A committee of citizens of Washington and Baltimore, headed by Thomas F. Walsh, arrived in New York Tuesday morning to present to the Aero Club of America their reasons for wishing the international aeroplane meet next year to be held near their cities.

The movement to have this aviation event held in Washington was started soon after Glenn Curtiss won the international trophy at Rheims. Later the citizens of Baltimore organized an aero club and formed a partnership with the Washington men, whereby the two cities were to pull together for the meet. Both cities have raised funds which together will guarantee $100,000 for the expenses of the meet.

The Wright brothers and Glenn Curtiss have been invited to be present when the matter is discussed, at a dinner to be given at the Metropolitan Club in New York Tuesday night, by Mr. Walsh. A committee of the Aero Club of America will be present, as well as several members of the Wright syndicate.

OBSERVED BY AN ELECTRICIAN ABROAD

EMIL GRUENFELD, chief engineer and designer of the Baker Motor Vehicle Company, has just returned from a visit to European centers, and has expressed some interesting opinions on foreign progress. The most remarkable tendency, Mr. Gruenfeld says, is that toward shaft drive. Panhard, Benz, De Dietrich, Mors, Fiat, Berliet and others who formerly used chain drive exclusively, are all changing to shaft drive.

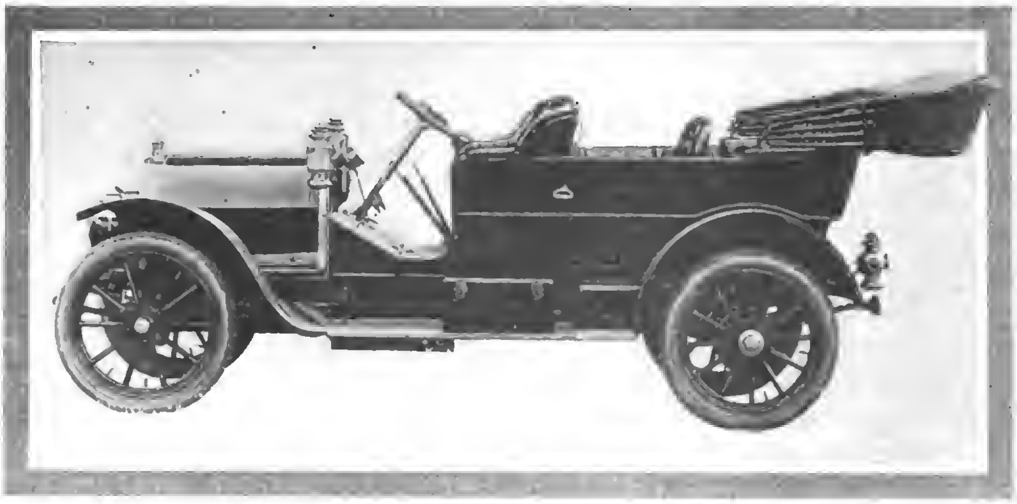
The greatest objection to European electrics, Mr. Gruenfeld says, is the use of very thin plates in the batteries, which, although they give a greater initial mileage, are too short-lived to be practical. The series-wound motor is becoming standard, and all the later models are of the single motor type with double speed reduction and shaft drive. The drum type controller is standard, also, and the electric brake and "recharging point" formerly used have been discarded.

European electro-chemists experimented with alkali batteries for many years, but could not overcome the disadvantages of the great potential drop under overloads and the limited recuperative power, a fault which the late American batteries of this type still show. For these reasons the pasted lead battery is almost universally used.

Solid and cushion tires have both been tried abroad, especially for taxicabs, but on account of the vibration and consequent loosening and breaking of mechanical parts have practically been discarded. Even the electric trucks and buses are being equipped with pneumatic tires of the twin and triple variety; that is, with two or three individual tires side by side on the same wheel. European cities are much more congested than those in this country, which gives the electric an added advantage. Mr. Gruenfeld sees great possibilities in the export trade.

GAETH STANDS PAT ON ITS 1909 MODELS

CLEVELAND, Nov. 22—For the season of 1910, the product of the Gaeth Automobile Company will show so few changes as to warrant the statement that the company is "standing pat" on its last year's model. This is praiseworthy, for it shows that the business has reached a stable foundation when no changes are brought out or suggested by another twelve month's use.



The 1910 Gaeth Is the Twin Brother of the 1909 Gaeth

Thus the changes for the 1910 car include such microscopic alterations as a two-inch addition to the length of the rear springs, as well as changing the material to vanadium steel. Then the valve sizes have been slightly increased to correspond with the modern tendency toward very large valves. Also the wheelbase has been increased by 6 inches making it now 120 inches. This is taken advantage of in the body, particularly in the length and foot room of the tonneau. A most noticeable tendency is the offering of dual ignition as an option, the second system taking the form of a high-tension jump spark outfit, with a Bosch magneto supplying the current.

Since this firm has always been a steadfast advocate of the low-tension system, this addition is noticeable. The make and break type is still put on as the regular ignition, in which a Bosch low-tension magneto supplies the current, the other being added only upon special request.

Distinctive describes the Gaeth clutch, which is unchanged. This is of the contracting band type, acting upon a special drum within the flywheel. The means of operation differs from the conventional, in that the pedal which operates it works backward to release, rather than the ordinary clutch pedal which works forward that is, taking the foot off of the clutch pedal releases the clutch. Some of the other features of the single chassis to be produced are: Double brakes, both placed upon the rear wheels and drop-forged crankshaft. It will be recalled that the motor is of the four-cylinder type. of 4 7-8-inch bore and 5 1-4-inch stroke. This is a long-stroke motor, and should deliver more than 40-horsepower.

FIRST GREAT WESTERN THIRTY OUT OF THE FACTORY

PERU, IND., Nov. 22—Interest now is concentrated wholly upon the newer models, designated by the manufacturers as 1910 models. The first of these are beginning to come out of the various shops all over the country. The illustration on this page shows the first product of the factory in Peru, Ind., of the Great Western Automobile Companies to bear the date of 1910. This is but a toy tonneau job and intended to seat only four. That the space allowed is unusually liberal is proved by the picture, which shows a seating capacity of five people. This comfort is a point which is often overlooked in the selection of machines, despite its great value and real necessity. The five men shown in the car, as illustrated, are Wm. Crossley, engineer, driving, and at his side, E. Mack Morris, general manager. The passengers in the rear seat, reading from left to right are: Paul Creighton, superintendent; R. H. Bouslog, secretary, and R. A. Edwards, director. Special attention is called to the enclosing sheet metal protection for the passengers, visible along the side of the car, just below the frame, and extending from the latter to the running board. This is a recent addition to the construction of the car, and is intended to protect the passengers from mud or dust, which would be thrown up.

Great Western Toy Tonneau with Five Notable Passengers

EARLY DELIVERIES OF NEW MOON MODEL

St. Louis, Nov. 22—Year by year the deliveries of new model cars has worked back from the fall of the year of the model to the late fall of the previous year. The best result of this has been to put the new cars into the purchaser's hands at the actual beginning of the year. As an instance of early deliveries now being made, may be cited that of one of the firms located in this city. The Moon Motor Car Company will commence to make regular deliveries in December of its new model, the Moon Thirty, which sells for $1,500. The car is new in a sense that it is being shown to the public for the first time, and it has been running for nearly a year, undergoing rigorous tests, and began to be built two years ago.

This Thirty is unusual in several respects, particularly noteworthy in a car to sell for so modest a price. Unlike most low-priced motor cars, the motor is suspended in the most approved method, without the use of a sub-frame. The gears operating the half-time shaft and pump are of the helical type and noiseless. Lubrication of the bearings of the motor is by force feed, a dash gauge indicating the pressure. Two and one-half gallons of oil carried in the self-contained reservoir is sufficient to lubricate the motor for 500 miles without attention.

A four-cylinder water-cooled motor with a bore of 4 1-2 and stroke of 5 inches, gives an ample 30-horsepower. It is cooled by extra large water jackets, a positive pump and special fin tubular radiator of ample size. The crankshaft of heat-treated steel, ground to size, is 1 3-4 inches in diameter. The valves are on opposite sides and mechanically operated; they are constructed of steel with nickel-steel heads, bevel-seated.

One finds the frame is such as is used on the most expensive motor cars. It is of cold-rolled pressed steel, 4 inches deep with 3 1-2-inch drop in the rear to allow for full elliptic springs. In front it is narrowed 3 inches to insure turning in a small space. The front axle is I-beam, one piece, drop-forged, with spring seats 4 inches wide forged integral. The rear axle is semi-floating, the live shaft being 1 3-8 inches in diameter and the material 3 1-2-per cent nickel steel. The axle tubing is 2 1-2 inches in diameter of seamless steel. The transmission is integral with the rear axle.

Being provided with a magneto, there is no commutator, and a consequent absence of surplus wiring. The car is sold with two oil side lights, tail light, horn and complete set of tools, for $1,500. The purchaser has the choice of three styles of body—touring car of the five passenger type, baby tonneau, and roadster. The car has a clearance of 11 1-2 inches, 110-inch wheel base, and tires 34 x 3 1-2 all around.

INTER-STATE "THIRTY" PRICE NOT REDUCED

In the description of the excellent car made by the Inter-State Automobile Company, Muncie, Ind., which was given in The Automobile for November 11, the statement was made that "this one belongs in the $1,500 class." This statement in itself would not have been misleading had it been explained and the real price of the car mentioned. As it was, however, the price was accidentally omitted, and the statement as quoted above was not explained.

What was actually meant was this: beginning about a year and a half ago, when the first of the cars listing at $1,500 and close to that were brought out, the phrase "$1,500 class" was coined to express the idea that a car belonged with these cars. Many of these cars actually listed as low as $1,200 and still others ran up in price as high as $1,800, but they were gathered together in one class, because of being natural competitors.

This class has grown and grown each year in both numbers and quality, so that it represents the logical middle or medium price car of today. The intention of the aforementioned remark was to class the Inter-State Model 30 with these cars, and not to indicate any lowering of the price. On the contrary, the demand has been such that an increase would be more reasonable.

TABLE OF WHEEL SIZES AND RIMS

Very few people, aside from those directly concerned with the wheel, rim or tire business, realize the large existing differences in wheel sizes demanded by the various makes of tire. The ordinary person thinks that he may choose his tire at random. So he may, but after that the wheels have got to be changed so as to allow of the use of that particular tire. The attached table, compiled and distributed gratis by the Firestone Tire & Rubber Company, Akron, O., shows this plainly, and in exact figures. The sizes there given demonstrate this fact more plainly than hundreds of words would. Thus it shows that having 36 by 4 1-2-inch tires on a car, say Fisk demountable, should it be desired to change to Continental demountables of an equivalent metric size (920 by 120), it will be necessary to have wheels

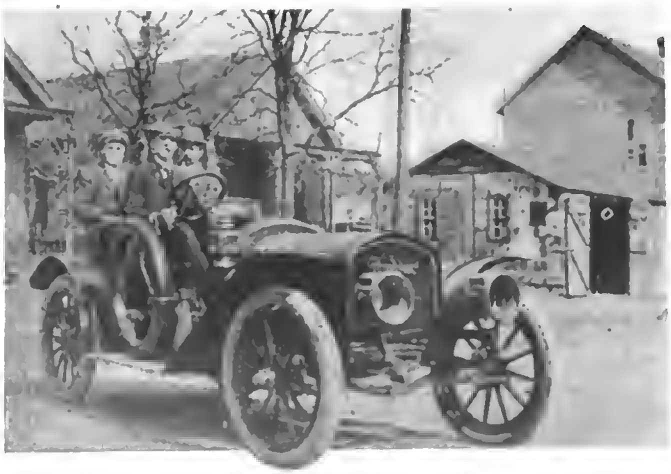
810 X 90	31 X 3½		850 X 120	33 X 4½
840 X 90	32 X 3½		880 X 120	34 X 4½
870 X 90	34 X 3½		920 X 120	36 X 4½ or 5
910 X 90	36 X 3½		1020 X 120	40 X 4½ or 5
960 X 90	38 X 3½		1080 X 120	44 X 4½ or 5
1010 X 90	40 X 3½		935 X 135	36 X 5½

increased in diameter from 22 13-16 inches to 25 3-16 inches. Even then, if it was later on desired to change to Fisk bolted on tires of the same size, a 25 1-2-inch wheel would be required. Also, clincher and universal tires would call for wheels 26 21-32 inches in diameter. Since no putting-on tool for wood wheels has ever been invented, this means new wheels every time.

Wilmington, Del.—Work has been about completed upon the new garage of the Wilmington Automobile Company, on West Tenth street, and the concern expects to occupy the building some time in September. It will then have one of the most completely equipped and spacious garage buildings in the country, and the largest in Wilmington. The structure will be 85 by 114 feet in size and three stories high. The first and second will be used for storage and the third for a repair shop. The agency for the Peerless, Stevens-Duryea and Franklin cars is held.



Texan Travelling Salesman Who Drives a Rambler

M. M. Hinton, who makes his headquarters in Dallas, Tex., has a territory where people order their groceries by long-distance telephone and ride twenty miles to visit a neighbor. He has driven his Rambler fourteen thousand miles while making his rounds

INTER-MOUNTAIN AUTO SHOW AT SALT LAKE

Salt Lake City, Nov. 20—The great Inter-Mountain West is to have an automobile show. It will be held in this city, the fast growing metropolis which furnishes cars to Utah, Idaho, Wyoming, Nevada, Montana and western Colorado. The dates are Feb. 19 to 26. Such is the announcement of the Utah Automobile Dealers' Association. This organization, composed of the leading dealers of the State have already secured the Auditorium with a floor space of 150 by 200 feet. A local firm of architects is now engaged in laying out plans for the booths and an extensive scheme of decoration.

W. D. Rishel, the well-known Salt Lake newspaper man, has been engaged as manager and has already opened offices at 1-3-5 East First South street and began active work.

Salt Lake is a mecca for cattlemen, sheepmen and mining men during the long winter months. These men are the largest purchasers of machines in the West, and it is possible many sales can be booked during the show.

HARTFORD WANTS NEW ARMORY FOR SHOW

Hartford, Conn., Nov. 22—Now that the new State armory and arsenal is completed the old talk of holding the next Hartford automobile show there is revived. The new structure has a greater floor space than Madison Square Garden, hence it is obvious that it would be an admirable place in which to hold an exhibition of this nature. However, the building is limited strictly to the use of the state militia, and no civic functions of whatsoever nature may be held here. The location is good and cars could be run in off the ground floor without difficulty, and in addition to the main floor there are galleries and side rooms as well as a spacious basement. That a motor car show in such a building would be a drawing card is obvious, for it is a certainty that each and every dealer in the town, and now there are more than last season, would do all possible to make a good exhibition. But the State of Connecticut says, "No," so there the matter ends, and the dealers can but sign and find a smaller hall.

SYRACUSE SHOW, WEEK OF MARCH 12

Syracuse, N. Y., Nov. 20—The Syracuse Automobile Dealers Association has practically decided to hold its show this year the week of March 12. Instead of holding it for four days, as last year, it will next spring be put on for a full week, in the New York State Armory, every inch of space being occupied according to predictions. Already committees are commencing to figure upon the details of the big exhibition.

TWYMAN SAYS SOUTH IS GREAT FIELD

Louisville, Ky., Nov. 22—B. W. Twyman, who is thoroughly familiar with trade conditions of the automobile industry in the South, has returned from Atlanta. In discussing the Atlanta show, he said:

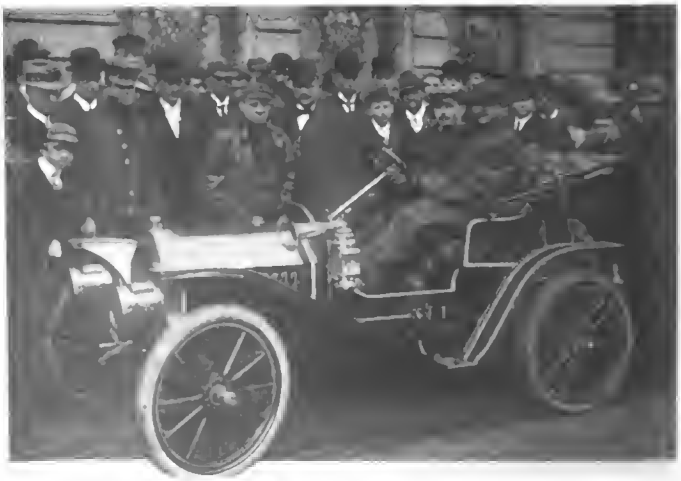
"It is very doubtful whether the automobile manufacturers in the United States realized the important part the South is destined to take in the automobile industry until after the Atlanta show. While all of the principal manufacturers were more or less soliciting business and taking just what was handed to them almost voluntarily, they did not fully realize the immensity of the possibilities of the States south of the Mason Dixon Line. The show, while not so large as those given in New York and Chicago because the building would not permit it, was in every way an ideal, modern, up-to-date automobile show both in decoration, arrangement, management and all. It is usually estimated that about one in every twenty persons who visits an automobile show in New York or Chicago are really interested in the purchase of a machine, while in Atlanta, I am satisfied that this could easily be reduced to one in five. What surprised me most was the amount of knowledge of automobiles and their construction found in the average prospective customer. This shows very conclusively that the automobile is receiving serious consideration by the entire South."

TEST PROVES WORTH OF LITTLEST CAR

Detroit, Nov. 22—With the idea of thoroughly testing out the ability of the "Littlest Car," the manufacturers of the Demotcar have sent two of the sturdy little fellows on State wide tours. One of these will be across Michigan and the other will traverse Ohio. How far the cars will go beyond has not yet been determined, but the marvelous manner in which they have taken to the unusually severe work may bring forth many thousand miles of additional tour.

The object of the test is to give the runabout a test that will prove its dependability beyond question. Leaving the Hotel Pontchartrain, Detroit, last Monday, the Michigan car traveled through Ypsilanti, Ann Arbor, and Howell, en route to Lansing. On Friday evening, O. B. Harper, of Harper & Aldrich, the Lansing and State agents, wired the factory that up to that time every one of the fifty-seven varieties of bad road had been encountered and successfully overcome. Considering the season of the year, with its deterrent effect on all touring, the showing of this $550 car has been such as to convince the most skeptical of its real merit.

In the illustration is shown the Michigan car as it appeared just before leaving Detroit for its dash across the State. This cut shows that the car is a regular stock model, and not a car especially prepared for this trip. It may be noted, too, that the driver and passenger were not particularly light weights.



Demotcar Leaving Detroit for Trip Through Michigan

Getting Ready for the Night On a Camping Trip

The illustration above shows two important members of the Maxwell-Briscoe Motor Co.'s official family pitching camp for the night. This was upon the recent occasion of Ernest Coler and J. D. Maxwell's going deer hunting in a Maxwell "Sportsman"

Moon Shines All Night—The Moon Motor Car Company's St. Louis plant has been running overtime for several weeks and a large force of men is now working at night in the machine shop. Deliveries of 1910 cars are now being made, and beginning in December the factory will turn out five or six cars daily. In pursuance of the company's policy to install the most modern machinery, several new tools have been put in the machine shop during the past week. One of these is a specially made boring machine, which drills six large ports at one time; this is used on the cylinder heads of the new "30." Fifty-four chassis were counted in the assembly room at one time last week, 38 being of the new model 30.

Robbed of $20,000 by Employee—Coincident with the disappearance of the former paymaster, Chauncey W. Hammond, the E-M-F Automobile Company, of Detroit, now controlled by Studebaker interests, found itself minus a week's pay roll, amounting to more than $17,000. A short time after the loss was discovered and reported to the police young Hammond walked into one of the police stations and gave himself up, declaring that he knew nothing of the theft. The abstraction of the money was a very clever job, paving bricks being substituted for the actual "mazuma," without the change being detected, until the satchel supposed to contain the money was opened at the factory to start paying off the company's employees.

Boston Auto Row Moving?—The Peerless Motor Car Company has leased for 20 years a building covering an area of over 10,000 square feet on Beacon street, near the intersection of Commonwealth avenue, which is being built by Eugene N. Foss. Another section of the same property is reported to have been taken by a second well-known automobile concern, and the chances are that the remainder will meet the same fate. The property is within two blocks of the terminus of the proposed Riverbank subway, and is in the hands of Lawrence Whitcomb, of Whitcomb, Wead & Company, who is also treasurer of the National Brake & Clutch Company.

Franklin's Stock of Tubing—Over ten miles of steel, brass and copper tubing—56,527 feet at the last inventory, to be exact—are kept in stock at the Syracuse, N. Y., factory of the H. H. Franklin Mfg. Co. This stock, it is said, would be exhausted in six months if no more was purchased. The larger sizes are used for the exhaust piping and for axles. Tubular axles are retained as a feature of Franklin design because the company believes that they are stronger and lighter than the I-beam type. The metal used in this tubing is 3 1-2 per cent nickel steel, with an approximate tensile strength of 240,000 pounds per square inch.

Economy of Motor Farming—Reports from Oberlin, Kan., tell of a farmer in that vicinity who recently finished plowing and seeding a thousand acres of wheat, using a four-cylinder, 90-horsepower gasoline tractor. He used 2,107 gallons of gasoline, costing $266.84, and about $90 worth of lubricating oil. Expenses for men and their board, and incidentals were $250. The total cost was about $600, or 60 cents an acre. Four drills were used, covering 36 feet at a time, and the packers were hitched just back of the drill so that drilling and packing were carried on at the same time, thus economizing still further.

Lexington Goes to Connersville—According to information received from the Lexington Motor Car Company, all previous reports concerning this company's intentions have been totally incorrect. The Lexington Company will not stay in Lexington, despite the best efforts of that city's population; but, on the contrary, will remove to Connersville, Ind., shortly after January, as the local capitalists failed to secure [illegible]95 shares of stock held by E. D. Johnson, president of the company, who is a Connersville man and most interested in the company's removal.

On the Banks of the Wabash—The Muncie Clutch & Gear Company, of Muncie, Ind., has ben consolidated with the Wabash Gear Works, of Terre Haute, Ind. The latter concern has been in business for some years, while the former is comparatively recent. The new management will be largely under the control of A. W. Wagner, who has become president of the Warner Gear Company, and H. L. Hooke, formerly of Muncie, who has become secretary. With greatly increased capacity, the company will continue the manufacture of change-gears, clutches, levers, etc.

Lecture on Battery Maintenance—Bruce Ford, of the Electric Storage Battery Company, delivered an interesting lecture last week on the care and operation of electric automobile batteries in the Chamber of Commerce, Washington, D. C. The lecture was illustrated by lantern slides and was largely attended. Electric automobiles are very popular in the Capital City and their owners derived much useful information from the evening's talk.

To Make Steering Wheels—Detroit's prestige as an automobile manufacturing center will be increased by the establishment of the Detroit Steering Wheel and Wind Shield Company, incorporated last week. The company is capitalized at $100,000, of which half has been paid in. The stockholders are Albert S. Keen, W. H. Honkle, Howard E. Coffin, Hugh J. Denk, Titus Denk, John A. Galvin and Thaddeus Galvin.

Needed 500 More Men—The Maxwell-Briscoe Motor Company's Newcastle, Ind., plant sent in the biggest request for help yet received by the free employment bureau in the office of the State statistician at Indianapolis when it telephoned for 500 men to be sent immediately. A rush of orders was the cause of this sudden increase in the regular working force of the factory.

Error in Hartford Advertisement—In the advertisement of the Truffault-Hart-

One of the Assembling Rooms at the Rider-Lewis Factory, Anderson, Ind.

ford shock absorber last week a typographical error made it appear that these devices were fitted by manufacturers only at extra charge. This was, of course, misleading, as a number of prominent makers include these shock absorbers in their stock equipment on every car which is sent from the factory.

Grabowsky Building Addition—The Grabowsky Power Wagon Company is building an addition to its present factory building in Detroit. This move has been found necessary in order to take care of the demand. The company is also looking about for a suitable building to acquire in addition to the one now occupied.

And Another Detroiter—Another new automobile manufacturing company is to be located in Detroit. The newcomer is the Abbott Motor Company, which has a capital stock of $300,000 and has just filed articles of incorporation at Lansing Plans are said to be in preparation for the erection of a large factory.

Receiver for Rubber Company—Chester O. Henderson, of Indianapolis, made application recently for a receiver to be appointed for the Goshen Tire & Rubber Company, and accordingly Judge Dodge, of the Elkhart circuit, named George P. Rowell to fill the office. It is likely that the business will be wound up.

Chadwick Doubles Capitalization—The Chadwick Engineering Works, of Pottstown, Pa., which makes the six-cylinder Chadwick cars, has increased its capital stock from $500,000 to $1,000,000.

IN AND ABOUT THE AGENCIES

Studebaker, Atlanta, Ga.—The Studebaker Automobile Company has purchased the interest of G. W. Hansen and his associates in the Georgia Motor Car Company, which will be made subsidiary to the Studebaker company and constitute a branch of the South Bend concern. Mr. Hansen will continue as manager. The branch will control the two Carolinas, Georgia and Florida. A new building is under construction at 45 Auburn avenue. It is estimated that one-twentieth of the Studebaker output will pass through this branch.

American Simplex and Velie, Syracuse, N. Y.—Melville W. Kerr and James E. Doane have combined under the name of the Kerr-Doane Motor Company to handle the American Simplex and the Velie. The new firm intends to build a handsome garage and showroom and is now looking for a suitable location.

Moon, Atlanta, Ga.—The McConnell-Kurfees Company, of 30 North Pryor street, has contracted with the Moon Motor Car Company, of St. Louis, for its agency in Georgia, the Carolinas, Florida and Alabama. Sub-agencies will be established in the latter States.

Ohio, New York City—The Harry S. Houpt Company has been made Eastern distributor for the Ohio, manufactured by the Jewel Carriage Company, of Cincinnati. The New York office of the Houpt Company at Broadway and Sixty-eighth street will be headquarters.

Koehler Lines, Newark, N. J.—The H. J. Koehler Company, which holds the New York City and vicinity agencies for the Hupmobile and Rider-Lewis, has purchased the property at 289-293 Halsey street, Newark, N. J., which will be its headquarters for New Jersey.

Rambler, Newark, N. J.—The Newark Automobile Company has taken the Rambler agency for this section. At present the company is located at 151 North Sixth street, but hopes to move into its new building at 316 North Broad street by the end of the month.

Ohio, Forsyth, Ga.—The Ohio Motor Car Company, of Cincinnati, has contracted with the Georgia Automobile Company, of Forsyth, to act as its agent in Georgia. Branches will be opened in Macon and Atlanta.

Columbia, New York City—The Victor Auto Storage Company, metropolitan agent for the Columbia, is fitting up an attractive salesroom on Broadway, near Fifty-second street, in which to exhibit the 1910 models.

Cole, Savannah, Ga.—Leonard Cater and W. A. Logan have taken the agency for the Cole Motor Car Company. They will act under the name of the Cole Motor Sales Company, with headquarters at 140 Bull street.

Croxton-Keeton, Johnstown and Altoona, Pa.—S. W. Fisher, Pittsburg manager for the Croxton-Keeton Motor Company, has arranged for the establishment of agencies in Johnstown and Altoona, Pa.

Rambler, Brooklyn, N. Y.—Kenney Brothers, who have the local agency for the Rambler, announce that they expect to be in their new quarters at Bedford avenue and Sterling place not later than December 1.

Pullman, Atlanta, Ga.—The York Motor Car Company, of York, Pa., maker of the Pullman, is about to open a southern branch at 10 Auburn avenue, Atlanta, under the management of Capt. Heidt.

Great Western, Niagara Falls, N. Y.—The Great Western Automobile Company, of Peru, Ind., has made arrangements with Swick & Pattison to handle its line in Niagara Falls, N. Y.

Michelin Tires, Kansas City, Mo.—The Michelin Tire Company announces the opening of a branch at 1926 Grand avenue, Kansas City, Mo., under the management of Wayne Murray.

Republic Tires, Buffalo, N. Y.—The Republic Rubber Company, of Youngstown, O., has opened an agency at 46 Chippewa street, at which Republic tires will be sold.

Hupmobile, Jamestown, N. Y.—Jacobson Brothers, located at 701 North Main street, Jamestown, N. Y., have taken the agency for the Hupmobile for Chautauqua county.

Hupmobile, Savannah, Ga.—Messrs. Brockett and Hazzard have taken on the agency for the Hupmobile and will supply this section of Georgia.

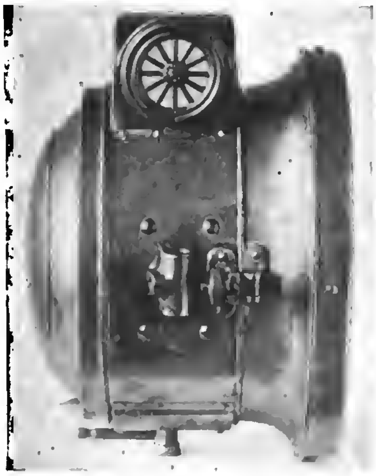
Inter-State, Pasadena, Cal.—Washburn Brothers, of 1032 Mission street, South Pasadena, have taken the agency for the Inter-State car.

Oakland, Syracuse, N. Y.—Willis & Van Brunt, agents for the Oldsmobile in this district, have added the Oakland to their list.

Regal, Tampa, Fla.—Minich & Kang have secured the agency for the Regal car in Tampa and vicinity.

THE RAMBLER'S SPECIAL LAMP

Another distinctive feature has been added to the new Rambler for 1910, by the equipment of all models with a Rambler lamp of special design. The top of the lamp is shaped to include the Rambler spare wheel in relief. This spare wheel, aside from its value to the owner, has become a most valuable asset to the Rambler people from an advertising standpoint. In every advertisement a circle display is used. At the upper points of the circle appear



New Rambler Lamp Design

the front and rear wheels of the car, between the two points the spare wheel attached to the car, and now the spare wheel appears in the lamp.

PERSONAL TRADE MENTION

Charles J. Horan, formerly with Ernest Flentje, of Cambridge, Mass., has taken a position with the Kilgore Mfg. Co., 585 Boylston street, Boston.

KEYSTONE OPENS PHILA. OFFICE

PHILADELPHIA, Nov. 20—The Keystone Lubricating Company, which makes Keystone Motor Oil, has opened an office and warehouse at 1327 Race street. Offices on the upper floors will be sub-let to concerns of good repute in the automobile accessory business. C. E. Huhn, formerly manager of the Puritan Soap Company of this city, has been appointed local Eastern manager of the automobile department.

RECENT TRADE PUBLICATIONS

L. Blériot, 16 rue Duret, Paris, France—Louis Blériot claims the honor of being the first to publish a catalog in which aeroplanes are listed on a commercial basis. His booklet contains fifty pages, artistically bound in rough green paper and well illustrated. The subject matter includes first the rough materials for aeroplane construction. The Blériot factory has unusual facilities for obtaining wood of the quality and grain necessary for this work, and also makes several forms of patented joints for the framework. Further on the Anzani, E.N.V., Gobron and Gnome motors are described and listed, and finally come the three types of aeroplane which Blériot has made famous: type XI, for one passenger, which crossed the English Channel; type XII, for two passengers, and type XIII, for three. The illustrations include photographs of many types of Blériot machines, dating back to 1901.

Sociétés des Moteurs Gnome, 49 rue Laffitte, Paris, France—Many of the successes of the Aviation Meet at Rheims were due in large degree to the efficiency and reliability of the Gnome motor. Although the most radical in its departure from standard practice, this motor has overcome prejudice and built up a most enviable reputation. As will be recalled from previous descriptions, it has seven cylinders mounted radially around a single stationary crank. The cylinders and crankcase revolve, and their weight acts as a flywheel. The 50-horsepower motor weighs 167 pounds, and the 100-horsepower, 14-cylinder type weighs 220 pounds, the cylinders of both being 4.33 by 4.73 inches bore and stroke. The motors are described in a single-sheet folder illustrated by photographs of Farman and Voisin biplanes in flight.

Société Anonyme Antoinette, 28 rue des Bas-Rogers, Puteaux (Seine), France—This well known maker of aeronautic motors and aeroplanes has issued a 12-page pamphlet in which its wares are described. Antoinette motors are made in three sizes, namely, 24 and 50-horsepower, 8-cylinder, and 100-horsepower, 16-cylinder, weighing 110, 198 and 330 pounds respectively. The Antoinette monoplane, made famous by Latham's daring feats, is also described at some length; it is distinguished by a truss construction, in which the members work only in compression and tension. These machines are made to order, many of the details being left to the discretion of the purchaser; the supporting surfaces varies from 300 to 400 square feet, with a weight, empty, of about 1,000 pounds.

New York School of Automobile Engineers, New York City—This organization has sent out to the trade and to others interested a pamphlet entitled simply "Motoring," and sub-titled "Extravagance and Danger vs. Economy and Safety." This case will certainly interest most amateur drivers. The school in question aims not so much to give practice in driving as to explain the underlying principles of the automobile. It is argued that anyone can easily learn to steer and change gears, and make a show of being a competent driver, and yet be completely unnerved by some slight but unusual accident which he has not encountered before. Such untrained drivers are dangerous not only to those who ride with them, but to all who use the same thoroughfare.

Chas. E. Miller, New York City—In preparation for the Atlanta Show this well-known manufacturer and jobber of automobile supplies has brought out a 100-page advance catalog for 1910, of which no less than 75,000 have been ordered from the printer. These will be distributed at Atlanta and at the other automobile shows. Emblematic of the scope of the catalog is the front cover, which shows an automobile in the center, and a motorcycle, a commercial truck, a motorboat and an aeroplane respectively in the four corners. As usual, the articles listed in the catalog include about everything that an automobilist could desire.

West Side Y. M. C. A., New York City—One of the first to start an automobile school, this hustling organization has taken up aeronautics, and under the direction of Wilbur R. Kimball has already a prosperous class in this new science. The aims and methods of the course are set forth in a pamphlet entitled "Aeronautics." The subjects of instruction include the law of gases, resistance and supporting power of the air, shapes of surfaces, kites, lift and drift, soaring and gliding flight, screw propellers, motive power, power-driven models, man-carrying apparatus, superposing surfaces, equilibrium, control, transmission systems and dirigible balloons.

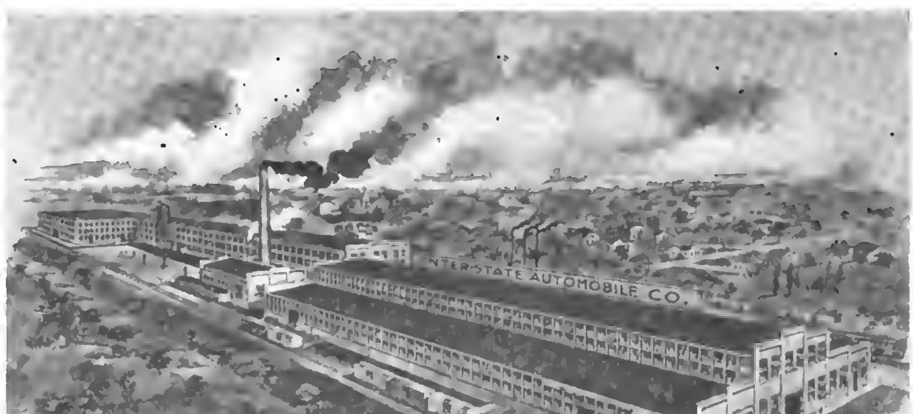
Rockwell Furnace Company, New York City—This catalog should be of great interest to automobile manufacturers and repairmen, listing and describing as it does many kinds of furnaces for forging and welding parts. The Rockwell furnaces are adapted to the use of either oil or gas, and seem neat and workmanlike in construction. The catalog contains 40 pages, 9 by 12 inches, and is profusely illustrated, both with pictures of the various machines themselves, and of factories showing them in actual use. Anyone who contemplates installing a furnace for forging and welding work would do well to consult it.

The American Oil Pump and Tank Company, Dayton, O.—"Dayton Leads the World" is the proud inscription on the cover of this booklet, and it is emphasized by a Wright aeroplane in full flight above the "American" pump which occupies the foreground. These pumps are all double-acting, giving a rapid and continuous flow of liquid, and are made in several styles and sizes, adapted to different forms of storage. The same company makes tanks and is prepared to furnish complete storage outfits, for either private or public garages, and for either gasoline or lubricating oil.

Motor and Manufacturing Works Company, Geneva, N. Y.—"Ejector" Mufflers form the primary subject of this company's catalog, which might well have been brought out by the Society for the Prevention of Noise. "Ejector" Mufflers are claimed not only to discharge the exhaust gases without noise, but also to reduce the pressure in the exhaust pipe below atmospheric, thereby creating a suction on the cylinder at the beginning of the exhaust stroke. Other products listed in the catalog are cutout valves, horn-blowing valves and foot pedals for their operation.

W. H. McIntyre Company, Auburn, Ind.—A striking cover of brilliant orange hue encloses the specifications of the 1910 McIntyre line, which includes pneumatic-tired vehicles of the standard type as well as the high-wheeled machines usually connected with this name. The new models follow the most advanced practice in having very large wheel diameters, the same being 36 inches on both of the two four-cylinder models selling at $1,250 and $1,750. A two-cylinder, $600 runabout also figures in the catalog.

Liggett Spring & Axle Company, Pittsburg—The present scarcity of automobile parts lends additional interest to the catalog of this maker of automobile springs and axles. The catalog in question is devoted to springs, and shows them in all the forms customarily used: full, three-quarters, and half elliptics.



Perspective View of Inter-State Factory at Muncie, Ind.

Information for Auto Users

Foy Electric Tail-Light—The oil tail-light, so often unreliable, has found a formidable rival in the Foy light, made by the Jordan Equipment Company, Beverly, Mass. This consists not only of the tail-light itself, with a tungsten-filament light, but also of a number-holder integral with the frame of the lamp, and arranged so that the number plate is illuminated by a broad band of white light. The number plates are interchangeable, so that different ones may be kept for use in different states, and changed with little difficulty.

The light is operated by an ordinary ignition battery, either storage or dry, and it is said by the makers that four dry

ELECTRIC TAIL LIGHT AND NUMBER PLATE

cells will operate the light with average running at night for ten weeks. The electric filament is German tungsten, cleverly hung up between two spring cushion terminals which prevent it from jarring out and also protect the filament. The lamp is fitted with a large red bull's-eye of the standard railroad type for signalling purposes, and the entire under part of the lamp, above the number plate, is a piece of heavy ground glass, which throws a well-diffused white light on the plate. Perhaps the greatest convenience about the lamp is that it is turned on or off by a switch, which can be placed anywhere within easy reach of the driver. The tail-lamp can thus be lighted without even stopping the car.

The lamp and holder are neat and attractive in appearance, and are claimed to cover the letter of the law in every State in the Union. The machine work is done by the Randall-Faichney Company, of Boston, which statement is a guarantee of excellence in this direction. The outfit sells for a reasonable price.

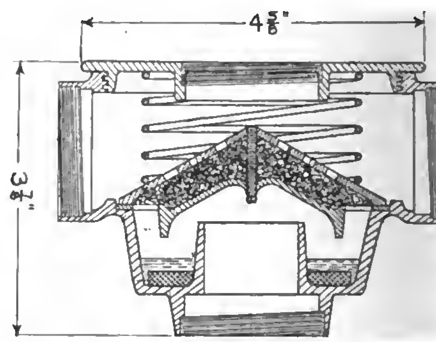
Perfection Magnetos and Battery Chargers—The Economy Mfg. Co., which makes these magnetos, has succeeded the Perfection Magneto Company, of Anderson, Ind., and is now located in Pittsburgh. Many of the former manufacturer's workmen have been engaged, and modern machinery has been installed to secure the production of the magnetos at a minimum factory cost. The jump-spark magneto is designed to be driven by friction or belt in any manner that will give the necessary speed of 2,500 revolutions. It has a drum type armature with laminated core, wound with double silk covered wire and thoroughly insulated. The magnets are of the Economy Mfg. Co.'s own make, of the best tungsten magnet steel. Brush holders are so constructed that the magneto may be run in either direction. Practically the same machine is adapted to service as a battery charger by the addition of an automatic cut-out to prevent discharge of the battery back through the magneto when the latter is idle. All that is necessary to install the battery charger is to adjust the machine so that its pulley makes the contact with the flywheel and to connect its two wires to the binding posts of the battery.

Vulco-Nu-Tread Kit—The old expression, "a stitch in time," is particularly applicable to fixing a cut in a tire casing. No matter how small the cut or hole may be, if it is neglected, sand and water or both will work into the fabric and loosen it from the tread. The Hazen-Brown Company, 100 South street, Boston, which is well known as one of the largest makers of shoe cement in the United States, has placed upon the market the Vulco-Nu-Tread repair kit with the design of meeting the requirements of just such a contingency, and saving the tire for a long period of future use. The driver of the car having one of these kits will be in possession of an outfit whereby repairs can be made immediately, thus saving tires from damage by delay, as the kit contains everything necessary for fixing any cut in a casing. It is packed in a neat wooden case, containing full directions for use.

Nu-Tread, which is a part of the kit, is also put up separately in collapsible tubes, and can be used independently of Vulcanoid—another essential of the outfit. Nu-Tread is virtually a rubber compound in a plastic form, and fills a cut satisfactorily with very little shrinkage, has good adhesive properties and is not easily loosened by wear. Vulcanoid is a fluid for cold vulcanizing, and the makers guarantee results when properly applied, and that it will perfectly cure the rubber.

In addition to the above, the Hazen-Brown Company is the maker of the Pluto vulcanizing kit which has proved so popular for cold vulcanizing; the Tire Doctor kit, which is a combination of both the Pluto and Vulco-Nu-Tread; the Pluto press, a handy tool with which sufficient pressure can be obtained to make repairs; Hazenoid rubber cement; mat and tire revivers, for giving a new finish to those articles; enamel reviver for automobile woodwork; alumino finish, a ready mixed aluminum paint for the engine and its accessories, which is waterproof, and does not tarnish; and an enamel reviver for polishing enameled bodies of automobiles and other highly finished wood or metal work.

Whiting "Airburetors"—O. J. Garlock & Company, of Palmyra, N. Y., have brought out two devices known as the "Airburetor-Filter" and the "Airburetor-Mixer," intended to improve the carburetion of an engine, working in connection with the usual carbureter. Both are intended to strain thoroughly all the vapor which reaches the cylinders, to eliminate every particle of foreign matter; and in addition—which may seem

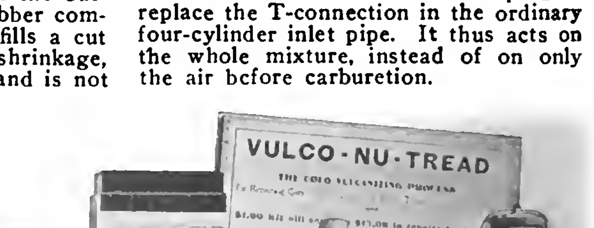


SECTION SHOWING AIRBURETOR CONSTRUCTION

strange to the autoist who has suffered from watery gasoline—both are intended to "humidify" the mixture by the addition of a very small amount of water vapor. The reason for this is the improvement in the running of the motor which is often noticeable at night, and which is supposed to be due to the humidity of the air after dark. A motor with a "humidified" mixture should therefore run as well by day as by night.

Of these two devices the "Filter" is intended to go on the air inlet to the carburetor, and the "Mixer" in the inlet pipe between the carburetor and the inlet valves. The "Filter" consists of a chamber full of asbestos fiber or steel wool through which the air is strained, and containing in the bottom a layer of "Humidifier Compound No. 17," which adds the desired moisture. The straining out of all dust in the air is believed to result in less friction deposit.

The "Airburetor-Mixer" is adapted to replace the T-connection in the ordinary four-cylinder inlet pipe. It thus acts on the whole mixture, instead of on only the air before carburetion.



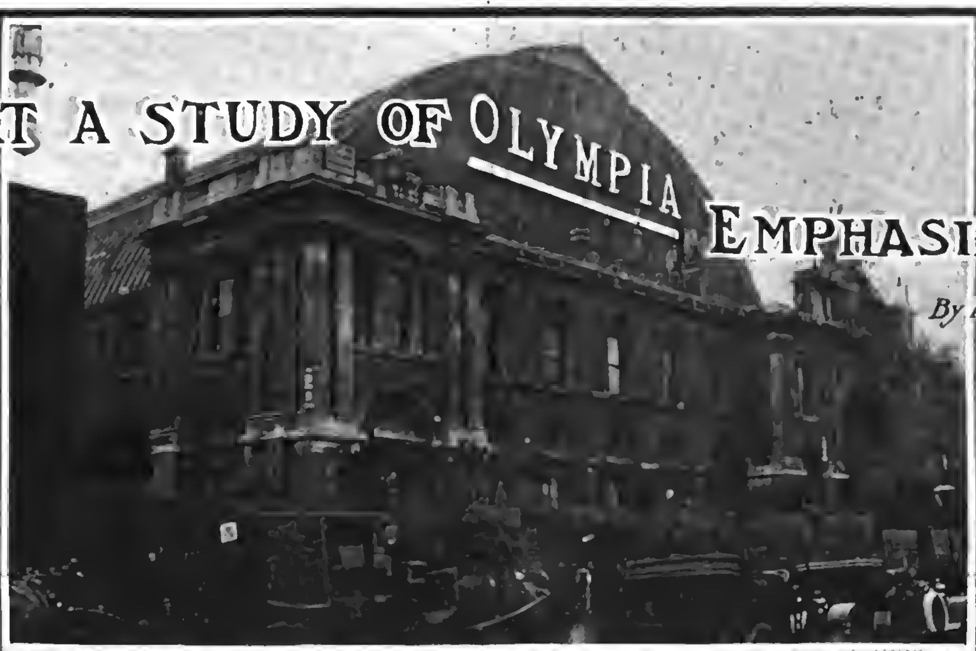
COMPONENT PARTS OF VULCO-NU-TREAD TIRE KIT

VOL. XXI NEW YORK—THURSDAY, DECEMBER 2, 1909—CHICAGO No. 23

THE AUTOMOBILE

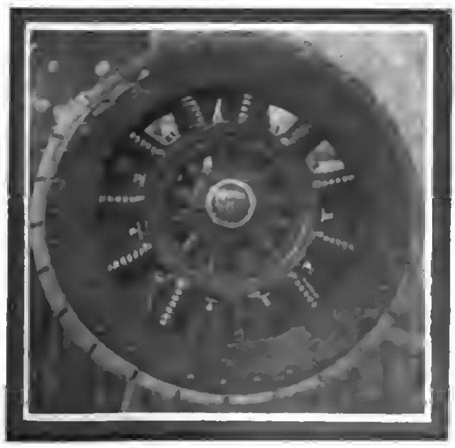
WHAT A STUDY OF OLYMPIA EMPHASIZES

By Basil Weston



The Great Olympia Show Building, London, Where Great Britain's Exhibition of Automobiles Is Held Annually

LONDON, Nov. 13—A detailed examination of the seven hundred or so cars exhibited requires at least two days, and at the end of this period one is driven to the conclusion that design is even further from finality than last year. Instead of settling down to one or more standard types the makers are all tending to develop their own ideas as to necessary improvements; with the result that almost every car presents new features of note—some useful and sound—others apparently the reverse. This is, perhaps, a natural stage in the development of the car. Some one has said, "It took five years to get the car to go and another five to keep it going." Apparently we are now in the third quinquennial period, in which makers are going to get the car to keep going well and without any attention from the user. Perhaps after this stage has been successfully passed we will find the industry settling down to the production of certain stereotyped models just as in the case of the bicycle industry which preceded it.

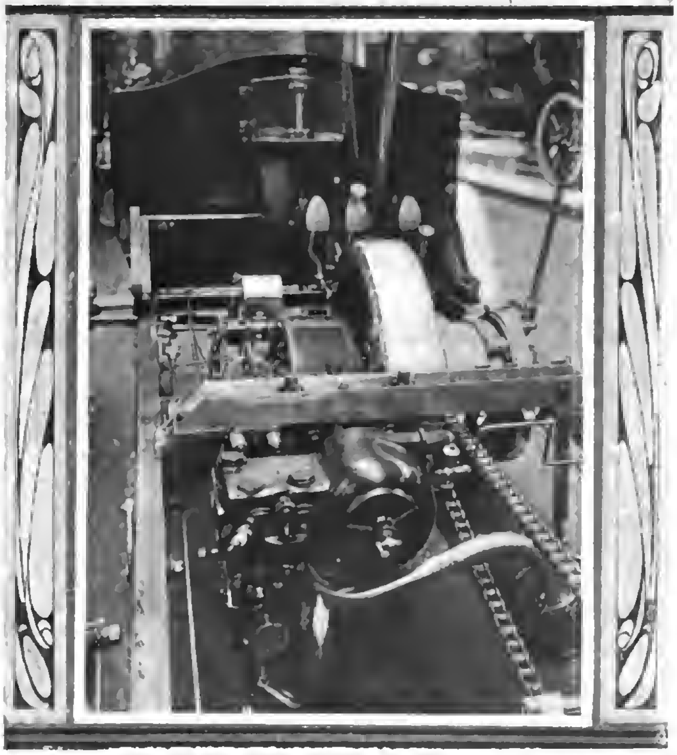


Latest Spring Wheel—The Sirdar

To return to the show. It may be interesting to review the stands in turn, noting down the main features which attract attention. Dealing with the cars in descending order of power and cost, there are a dozen firms which still favor the $5,000 car in spite of the high taxation ($200 per annum) likely to be imposed on this class. Rolls-Royce and Sheffield-Simplex specialize on big six-cylinder cars, while Napier, Daimler, and many others also favor the 60-horsepower, six-cylinder model, with the addition of other cars of more popular style and power.

The Rolls-Royce car is rated at 40-50 horsepower—this being an exception to the usual rule whereby British cars are known according to their R.A.C. rating. The six cylinders are cast in two blocks of three, a feature which has been copied by several other makers this year. All the valves are on one side, while the car-

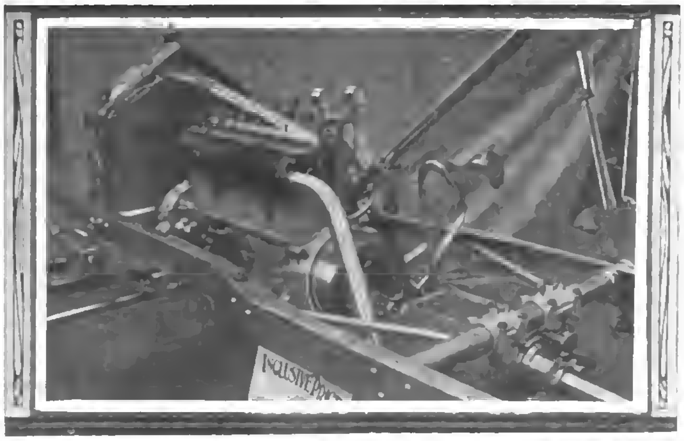
Hydraulic Transmission—Torbina Car



The Adams Car—"Only Pedals to Push"

bureter, pump, magneto and distributor for the battery ignition find accessible places on the other side. The inverted leather cone clutch and three-speed gearbox are of standard type, but the bevel-driven rear axle is provided with a triangular torque stay and radius rods of unusual proportions, for the makers attach special importance to this in connection with smooth driving and braking. The action of the expanding brakes in the rear hubs is equalized by means of a small differential gear placed in connection with the cross shaft which actuates the two brake cables. The springing and other features of the chassis are unaltered from last year with the exception that an air pump driven by the propeller shaft is used to provide the pressure for the fuel tank at the rear. This is in line with a movement of which many examples may be observed.

The most noticeable feature on the Sheffield-Simplex 45-horsepower, six-cylinder car is its "gearlessness," which, however, turns out to be more apparent than real. There is certainly no gearbox, in the ordinary sense of the word, and a straight propellor shaft extends from the clutch to the rear axle, giving a direct drive on which the car climbs hills with remarkable efficiency. In order to give the reverse gear, however, a small arrangement of gearing had to be provided at the rear axle bevel casing, and once this step was taken it was found no further trouble to arrange a low forward gear for emergency use. Hence this car is more correctly termed "gearboxless" than gearless. Another feature of interest is the control arrangement. There are the usual side levers and also two pedals. The left pedal operates first the clutch and afterwards the brake, while the second pedal, which is really a footplate sliding sideways, operates the carburetor throttle. This arrangement is found to be much more convenient to use than an accelerator pedal of the usual type. The front wheels are fitted with band brakes, which are operated by the foot pedal, while the rear wheel expanding brakes are controlled by the side lever. Detachable wire wheels are provided as standard.



Motor and Clutch Layout of the Crossley

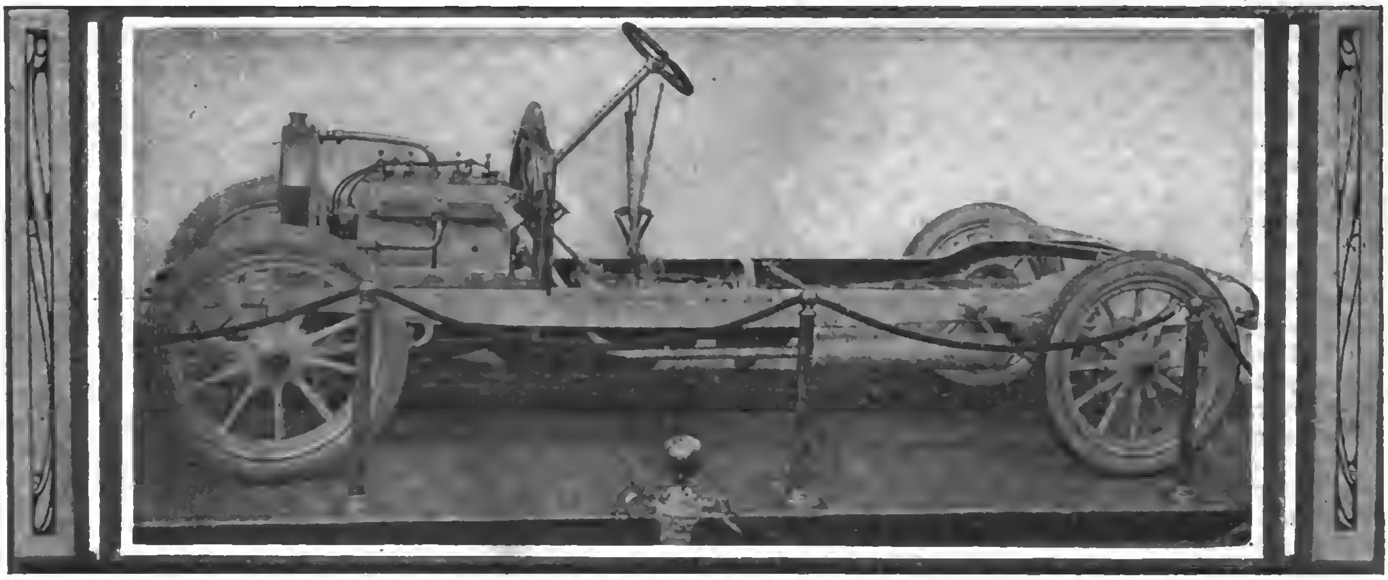
Napier Makes Both Fours and Sixes—The Napier firm has, for several years past, abandoned its former practice of making six-cylinder models only, and now provides cars of all types and powers, from the 10-horsepower, two-cylinder to the 90-horsepower, six-cylinder. On all the cars great attention has been paid to the elimination of all sources of noise, so that the firm has felt justified in adopting the descriptive name of "Noiseless Napiers." The larger models, and also the 15-horsepower type, are almost unaltered from last year, but the 15-horsepower car, listed at $1,750 chassis, has been improved in several ways. The four cylinders, 3 1-4 inches diameter and 5 inches stroke, are cast in pairs, and the valves, which are all on one side, are enclosed by detachable cover plates. The carbureter is of the "vaporizing tube" type, in which the petrol spray is completely vaporized in a narrow heated tube before the main air supply is added. This system has the advantage of enabling the hot jacket to vaporize the petrol in a thorough manner without decreasing the density of the charge. A single aluminum casting is used for the engine crankcase and the gearbox, with the result that the driving shafts are always in line. Roller bearings are used in the gearbox—an innovation for British design. The matter of ground clearance has been given careful attention, and a full 14 inches separates the lowest point of the engine from the ground. One of these 15-horsepower cars is shown with a special body for colonial use. Every tool or cooking utensil likely to be required is stowed away, and the hood is so arranged that it can be detached and used as a tent.

An equally interesting "15" finds place on the Daimler stand, this car and the 33-horsepower, six-cylinder being the new models for 1910. The other three cars—22, 38, and 57-horsepower—which proved so successful during the past season, have been retained almost without alteration, the only new features being the provision of a new semi-automatic lubrication system, whereby a pump supplies oil to troughs below the connecting rods, and the adoption of supplementary spiral springs at the rear of the frame. All the cars have, of course, Knight sliding sleeve engines.

The 15-horsepower model has already shown its popularity before the show commenced, and a very large demand is anticipated. The four cylinders are 80 x 130 mm. bore and stroke, with the usual Daimler detachable heads. These easily removed heads are found to be an advantage in that the combustion chamber can be quickly cleaned if this is found desirable after a season's running. There is no direct water connection between the jackets in the heads and those in the cylinders. Instead, the heads are connected in series, and the water passes through on its way to the radiator.

This last consists of plain flat copper tubes, without any gills or fins, which are arranged vertically, with their edges forward. The efficiency is considerably greater than with a radiator of the usual gilled tube variety, so that a smaller weight of water need be carried. The leather cone clutch and gearbox are of the standard type, and the drive to the rear axle is by a steel worm which actuates a phosphor-bronze worm wheel. The worm is placed below the axle, and hence, in order that the drive shall be in a straight line, and not impose excessive work on the universal joints, the engine is inclined at an angle of about 15 degrees. By reason of the arrangement of the oil troughs, this inclination has no effect on the working of the engine. This car is fitted with detachable wire wheels, and is made in two types, the roadster, with inclined steering, and the tourist. The price of the tourist four seater is $2,225. complete with lamps.

Product of a Battleship Maker—Like the Napier and Daimler firms, the Wolseley Company, which is a branch of Vickers & Maxim, the battleship builders, makes cars of all powers from 10 up to 60 horsepower. All have four cylinders, except the 10-horsepower, with two cylinders, and the 50-60-horsepower, which has six cylinders, all cast together—a practice also followed by the Panhard Company on their new 30-horsepower, live-axle car. The Wolseley engine is cast without the water jacket, this being formed of sheet steel, and fastened in place with screws. The valves are all on one side, and are inclined at an angle to the vertical, so that the combustion chamber is slightly lessened in size. The engine is lubricated by the splash of oil from the troughs situated beneath the connecting rods, these troughs being kept filled by a pump, as in the case of the Daimler. The carbureter has two jets, this being the usual custom with all engines of over 15 horsepower. This car has a four-speed gearbox and bevel drive, but the smaller Wolseleys have three speeds and worm device. All



Chassis of the French La Buire, an Example of the Popular 18-Horsepower Class

models have the road wheels fitted with Timken roller bearings.

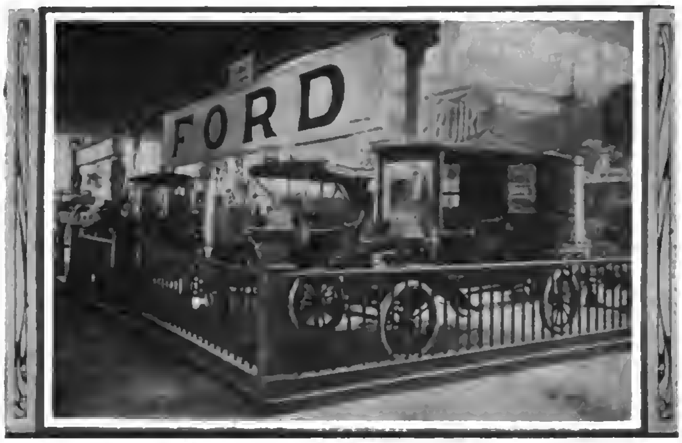
Two other well-known British cars which have in common several novel features are the Lanchester and N. E. C. (New Engine Company). Both of these cars have the engine beneath the front seat, and yet so arranged that all necessary parts are readily accessible. Both have also the engine inclined, so that the drive to the worm wheels at the rear axle is in a straight line. The Lanchester engine has vertical cylinders, four for the 20-horsepower, six for the 28-horsepower model, while the N. E. C. has four horizontal cylinders opposed in pairs. Dealing with the remaining features of the N. E. C. first; the engine can be started by the driver by means of a handle on the dashboard, the latter being hollow and carrying the petrol and oil. The steering wheel is arranged to tilt up out of the way, so that the driver may seat himself more easily. The brakes are water cooled, and the operating gear is arranged so that the throttle is closed when either brake is applied. The four springs are almost flat, and the ends can slide through the brackets, while radius rods prevent any movement of the axles. The gearbox gives four speeds, the gear being brought into mesh by an eccentric movement instead of the usual sliding action. Tbe Lanchester, on the other hand, retains the three-speed epicyclic gear, which has always been one of its special features. Worm drive and wire wheels are, likewise, special Lanchester features, both now becoming standard practice of other makers.

Application of the Worm Drive—The Lanchester worm, however, is special in that the worm is hollow in the center, with the result that the area of contact between the worm and worm wheel is greatly increased. So far, only the Lanchester Company has been able to produce a machine to cut these worms, with the result that their cars are much more quiet and efficient than other makes fitted with worm drive of the standard type.

One make of car—the Deasy—uses worms and wheels purchased from the Lanchester Company. These Deasy cars have the Renault type of radiator, as also have the Arrol Johnston cars. The Renault bonnet and radiator are particularly adapted for use in conjunction with bodies of the torpedo or flush-sided type—a fact which is taken advantage of in the standard models of both makes. The radiator design was one of several Renault patents which were recently revoked in this country on the grounds of non-working, and hence many more cars are likely to abandon the usual type of radiator in its favor—for there is no doubt as to which type is the more popular with the buying public.

The American Contingent—Of American cars, the White, Ford, and Cadillac are the only makes represented, though the Mitchell would have been staged had space been available. As it is, this last car is on view at a nearby garage. The White is shown by Mr. F. Coleman in both the steam and petrol forms, and, judging from the interest which the latter aroused, it would seem likely to prove as popular as the steam car has been. The Ford is only shown in one model—the 20-horsepower—which sells at $950. The Cadillac, also, has a great reputation over here, particularly for its reliability. The 10-horsepower, single-cylinder has not been altered since the memorable standardization test of a year ago. The 20-30, four-cylinder model has dual ignition and a longer wheel-base than before. The Cadillac representative, F. S. Bennett, is well pleased with the business prospects for next season.

Two other makes might be described as semi-American. These are the Adams and the Bedford. The Adams is shown in the 10-horsepower form, with the single-cylinder horizontal engine, epicyclic gear, and single-chain drive, and also in the 16-horsepower and the 30-horsepower types, with four-cylinder engine in each case. Epicyclic gears are fitted as standard to these larger cars, but a sliding-gear type of gearbox will be supplied if required. The Bedford is really a British-built Buick. It is rated at 15-18 horsepower, four cylinders, and has a type of three-speed epicyclic gear known as the Norman, wherein the planetary pinions revolve only at slow speed. The rear springs are complete elliptic—a construction only followed on these and the Austin cars. The Bedford car carries a guarantee for three



Ford Exemplified the American Light Car Ideas

years, the usual practice with other makers being to guarantee only for six months, or one year at most.

Italy Turns to Moderate Prices—In the medium power class there is an interesting group of Italian cars listed at moderate prices, consisting of Fiat, Itala, Lancia and Scat. The Fiat 12-14-horsepower has a bore and stroke of 80 x 120 mm, and the cylinders are cast in one piece, together with the base chamber. The magneto is high tension, and the carbureter a new type, with the jet chamber warmed by a water jacket. All the other parts of the car are standard, but the detail, finish, and general workmanship attract general attention. The Itala has the same bore and stroke, but is rated at 15 horsepower. It is almost exactly the same in appearance as the Fiat, save that it has no radius or torque rods. Its chassis price is $1,475. The Lancia 20-horsepower and the Scat 12-14-horsepower have no special details which call for comment except their general style and attractive appearance.

The British cars of this class which are most popular are the Crossley, Humber and Star. The first named, rated at 12-14 horsepower, has its four cylinders (size 80 x 120 mm) cast in one piece with the crankcase, while the gearbox has an extension which surrounds the flywheel and is bolted to the crankcase casting, thus giving the chassis a very neat appearance. The torque and radius rods are replaced by a steel tube, which surrounds the rear axle and terminates at the forward end in a spherical joint. The rear axle is so arranged that the propellor shaft and differential gearing can be removed without dismantling the axle. The car is fitted with internal expanding brakes on both front and rear wheels, and sells at $1,925 complete with five-seated body.

The 15-horsepower Star has come to the front lately on account of its high speeds—a standard type of two-seater having

White Showed the Gasoline Model beside the Steamer

been officially timed at Brooklands to cover a mile at the rate of 72 m.p.h. The engine has bore and stroke of 85 and 135 mm, and has a high compression and very large valves. The engine, clutch and gearbox form one unit, the latter providing four forward speeds with direct drive on the third.

As it was the Humber firm that first produced a popular four-cylinder car of moderate price, the Humber cars are always looked to as representative of British small car design. The only surprisingly novel feature is the adoption of four speeds instead of three on all models. This is rather contrary to the general tendency, but the designers stoutly maintain that if a small car is to give satisfaction for touring work it must be given such choice of gearing that all hills may be surmounted at a reasonably fast speed. On small cars the first, or emergency, speed is usually so low that it is hardly to be counted as a normal speed, and hence the car has but the second and top gears for ordinary work. When, as usual, only three speeds are fitted, the gap between second and top is too great to enable the car to do well in hilly country; hence the interposition of an extra speed between the two seems a reasonable proceeding. It will be interesting to see if other small car makers follow suit. Other Humber features are the use of thermo-syphon cooling and the provision of the Humber detachable wheels on all models, free of charge.

Several Small Piston-Valve Cars—In this medium power class there are three cars with piston-valve engines—the only apparent results of the experimenting which has been carried out on these lines by almost every maker. The three in question are the Hewitt, Bentall and Cooper. The 15-horsepower Hewitt engine has four cylinders cast in pairs, the bore and stroke being 90 x 108 mm. The eight piston valves are all placed on one side of the engine, and operate in long valve boxes placed alongside and at an angle with the main cylinders. These pistons are operated by connecting rods attached to the secondary shaft, and as they descend they uncover ports communicating with the carburetor and exhaust box respectively. The stroke of the valves is half that of the main pistons. The valves and ports are all water jacketed, and as the piston rings are never directly subjected to the heat of the burning gases, no lubrication troubles are experienced. An important fact is that the exhaust pistons travel downwards at maximum speed during the period of combustion, so that they are self driven and help to give power to the crankshaft. The inlet pistons are smaller in size and are so arranged that they are neutral as regards power. This engine has given excellent results on test, and when the system becomes better known the cars should become very popular.

The Bentall engine has likewise eight piston valves, but these are operated by rocker arms from an overhead shaft. The valve cylinders extend down the full length of the main cylinders, the inlet and exhaust sets being on opposite sides. These piston valves are hollow and are provided with ports about halfway in their length. When these ports register with ports cut in the cylinder walls the incoming or exhaust gases have free passage. As the ports will register on both down and up strokes of the valves it is only necessary to run the overhead shaft at one-fourth the engine speed, and hence the valve movement is correspondingly slower. The inlet and exhaust pipes are cast together with the cylinders, so that a very neat engine results. It might be expected that the hollow exhaust pistons would become excessively hot, but it is claimed that no trouble is apparent even after several hours' full load running.

The third new engine, the Cooper, is of the two-stroke type, having four cylinders, size 92 x 114 mm. Each cylinder has a piston rod and crosshead guide similar to those of a double-acting steam engine, and also a long piston valve, operated by a connecting rod from the half-speed shaft. Each crosshead is stationary, so that, as the working piston ascends, it draws the fresh charge through the piston valve into the space between itself and the crosshead. On the down stroke this charge is compressed and finally transferred through the center of the piston valve to the combustion chamber, where it drives out the exhaust gases through a port on the opposite side. The Cooper car has also an interesting rear axle drive, giving two direct forward speeds. This is effected by having two crown wheels of different size continually in mesh with two bevel gears, one or other of the latter being engaged with the propellor shaft by means of a double-dog clutch. A geared low speed and a reverse are also provided.

Many Single-Cylinder Cars—The small power class mainly consists of four-cylinder and one-cylinder cars, for the two-cylinder engine does not seem to regain its former popularity. There is, as a matter of fact, one six-cylinder car in this low-powered category—the 10-horsepower Delaunay-Belleville. This little two-seater has not been changed in design since last year, and good reports have been made of its running. There are many cars with monobloc engines of 8 to 12 horsepower, such as the French Delage, De Dion and Berliet, the German Adler and Opel, the Belgian Imperial and Metallurgique, and a dozen British cars. A notable newcomer to the four-cylinder section is the Renault, with 8-horsepower engine of 70 mm bore by 110 stroke. All these cars have three-speed gearbox and propellor-shaft drive, with raked steering column and two-seated body. The small car is now by no means the rough and incomplete vehicle of the style customary several years ago. In nearly every case the detail work has received as much attention as would be paid to the higher powered models. The reason for this is obvious, for all makers now look to the small and medium-sized car as the type for which the principal demand exists and recognize that this market is well worth securing.

Handsome Building Occupied by the London Ford Branch

Indicative of this fact is the small 7-horsepower car which the British firm of Austin has brought out. This has a single-cylinder engine of 105 x 127-mm bore and stroke and standard transmission, while all the parts, down to the gate change system and the internal expanding rear brakes, are exactly similar to those of the high-priced Austins. The price of this two-seater is $750 complete.

Other well-known single-cylinders are the Rover, Sizaire-Naudin and Jackson. The latter is curiously rated at 7-27 horsepower; the explanation being that the engine, 104-mm bore, is 7 horsepower by the R. A. C. formula, but on account of its stroke of 215 milimeters and high compression it develops 27 brake horsepower.

Fullest advantage is thus taken of the lessons of the French voiturette races and the Tourist Trophy. It will be interesting to note how the public receives this type of car, as its great power is gained principally at the expense of abnormally high piston speed. The engine has the further disadvantage of being very tall and awkward-looking. No one, however, has cast any doubt on its ability to develop its rated power. The general opinion is that such an extreme design will find little favor.

As Usual, a Hydraulic Transmission—Inventors have not yet abandoned the idea of the hydraulic transmission, which seems as fascinating as the various types of two-cycle and double-acting engines. The latest development in this line is the Torbina car, the vital part of which is illustrated elsewhere. The transmission device consists of a paddle-wheel with twin blades running in water; the blades can be deflected so as to displace a maximum or minimum quantity of liquid. In the maximum position the whole apparatus is automatically locked solid, and at the intermediate angles the slip is utilized to obtain the varying drives. The device is interesting principally as showing that the struggle for novelties has not ceased.

Competing Vehicles in French Commercial Trials Leaving the Garage at the End of the Trials

31 COMPLETED FRENCH COMMERCIAL VEHICLE TRIALS

PARIS, Nov. 30—Thirty-one commercial automobiles of various types and powers have been put on the scales, verified, and dismissed with a diploma certifying that they have made twenty-four distinct daily journeys, covering a total distance varying from 1,500 to 2,300 miles on schedule time, have carried a certain load and have used a certain amount of gasoline, alcohol, benzol, and lubricating oil.

This year's French industrial vehicle trials were organized with more assistance from the army than is usual, for the government, after experimenting cautiously for a number of years, has decided to inaugurate a system of subsidies, under which the purchaser of an approved type of vehicle can receive $600 the first year and $200 for each of the three following years, on condition that he presents his automobile annually for inspection and hands it over in case of mobilization. The type to which these favors should be extended was to be decided upon during these trials.

Regularity of running and economy in the use of fuel were the basis on which the trials were held. They were more difficult than on any previous occasion, for, with a view to eliminating the weaklings, the army authorities insisted on the date being October 15 to November 15. It is a time of the year when roads are liable to be heavy, putting engines and transmission to a more severe test than in summer.

Altogether Fifty-one Vehicles Started

At the start the competition united 51 vehicles. At the finish they were twenty-nine in the Automobile Club and army test, with two others that had entered under army conditions only. Two steamers which went through the preliminary formalities were withdrawn on the first day owing to the impossibility of arriving at an understanding on the fuel question. Two gasoline-electrics were withdrawn after the first day's run, owing to their obvious inability to compete on an economical basis with the gasoline products. There were two or three cases of gear failure causing withdrawal, and several of engine breakdown. In four or five cases, the mishaps were so slight that the competing vehicles were repaired and continued, though not given any official credit for doing so. Among these were two Berliet trucks, which on the first day ran into one another on a hill, owing to the brakes of the rearmost vehicle failing to hold. They were both repaired the same day and followed in the wake of the actual competitors, covering all the stages on schedule time. Officiallly, however, they were ignored.

The firms which figured best for team work were Saurer with five starts and five finishers in different classes, several of these being first prize winners. Delahaye with four starters and finishers; Bayard-Clement, also with four to start and finish; Aries with the same number, and Vinot-Deguingand with three out of three. De Dion Bouton lost two out of its four vehicles during the month; Peugeot lost two out of four, one of the two, however, continuing unofficially. Berliet also lost two out of four, the disqualified pair continuing without official recognition. Panhard-Levassor lost three out of four of its 15-horsepower trucks; Malicet & Blin had one failure out of three entrants, and Schneider lost both of its pair.

The reliability test was much more severe than is usual in competitions held by the French club. With the exception of the heaviest vehicles the average speed was fixed at 15 miles an hour, for daily runs varying from 60 to 120 miles. A maximum speed was also imposed, it being the duty of the military observer to see that it was not exceeded on any stage of the journey. If it were exceeded the vehicle had to be held back until the time limit had expired. Failure to make any one control on time meant disqualification.

Three Kinds of Fuel Used in the Contest

Three different types of fuel had to be used. For the first thirteen days, ordinary gasoline was supplied, and for three days over different routes the consumption was officially controlled. For one week the vehicles had to use alcohol, with two of these days during which the consumption was noted. Finally benzol was imposed for five days, with two of them under official control as regards consumption. As a proof of the thorough manner in which the fuel problem has been studied, it is only necessary to state that there was not a single failure successfully to use alcohol and benzol with no other adjustments than were possible during running time. Naturally they were prepared for this, there being a number of interesting carbureter adjustments with a view to economy, but the engines themselves had to remain unchanged. The only difficulty experienced was in starting up.

Fuel economy was not quite so remarkable as during last year's test, the reason being the increased average speed imposed. Another point of interest in the trials was that instead of the economy test being held at the end of the run over a comparatively short distance, it was carried on on seven different days, and for a distance of roughly five hundred miles. Another innovation was that the consumption of lubricating oil was controlled from the commencement to the end of the run, that is to say, for a period of 24 days and over a distance of 2,000 miles.

Horsepower Rating Was Not Excessive

With a view to figuring well on the economy basis the horsepower of the engines was kept as low as possible. In the class carrying loads not exceeding three tons, the rating of the engines varied from 14 to 22. Notable in this class were two Delahaye trucks with two-cylinder engines rated at 15-horsepower and having a bore of 3.9 inches and a stroke of 7.08 inches. Long stroke motors were in the majority, and further showed their superiority over the short strokes by winning in nearly all the classes. In section 5, for vehicles carrying more than a three ton load, two Delahaye trucks with four cylinder engines of 3 1-2 by 6 1-5 inches bore and stroke won respectively first and second prizes. On the official trials the two-cylinder Delahaye, carrying a useful load of almost three tons, would cover twelve miles to a gallon of gasoline. The four cylinder of the same make averaged 10 1-2 miles to the gallon with a load of 3 1-2 tons and a total weight of 6 tons.

The competing vehicles were divided into eight distinct classes, the first one being occupied entirely by a small two-cylinder Bayard-Clement delivery van which naturally won first prize. The second section, for delivery vans carrying a useful load varying from 1,324 to 2,645 pounds, was entered by De Dion Bouton and Vinot-Deguingand. The De Dion Bouton, a one lunger of 9-horsepower, broke down during the trials, leaving the four-cylinder Vinot-Deguingand the victor. In the third section there were only three entries, all of which went through to the end, Saurer getting first prize, Bayard-Clement second and Delaugere-Clayette third.

Saurer Figured Most Prominently

There was keen competition in the fourth class, where loads of 4,400 to 6,600 pounds were imposed. Here Saurer got first and third prizes, the two-cylinder Delahaye second and fifth and Vinot-Deguingand fourth and sixth. The others in order were De Dion Bouton, Aries, Panhard, Malicet & Blin, and Cohendet. The fifth section, imposing loads of more than three tons was, with the fourth, one in which the army was interested, and drew forth a strong set of competitors. Delahaye took first and second prizes, De Dion Bouton third and fourth, Aries fifth and sixth, and Malicet & Blin seventh. Whereas in the fourth class solid rubber tires had been carried almost without an exception, in the fifth section, having loads running as high as five tons, there were several cases of steel shod bandages all round and more in which rubber was used in front only.

The road trains and omnibus classes were not well filled. Saurer was the only one in the tractor class, his tractor having a load of four tons and his trailer one of three tons, pulled by an engine of only 4 by 6 inches stroke. The small bus class, having seats for 6 to 8 persons, was won by Bayard-Clement, with the same firm second and Peugeot third. Saurer was the only entrant in the large bus class, and was declared the winner.

The military section of the jury was more than usually afraid of cheating. When the competition had been brought to a close and final weighing in carried through, this operation comprising four separate weighings, with load, without load, with body and without body, the mechanical organs were tested. Every gasoline tank was sawn open in order to allow an officer to pass an electric lamp inside and examine thoroughly. One car had to have its differential entirely dismounted, another had to take its gearbox entirely to pieces, still another had to do the same with its steering gear, the same was done with a magneto, and even one of the solid tires of a Saurer truck was ordered to be cut off the rim. Evidently the military authorities had no intention of giving their award to a vehicle that had finished the test in a shaky condition or that had made use of any unauthorized methods.

De Dion Experimented with an Aluminum Bound Wheel

Latest Type of French Taxicab

PARIS, Nov. 30—A new type of taxicab is about to be put on the streets of Paris which has a certain general appearance to the electrics formerly employed by the New York Transportation Company. The resemblance, however, is only confined to the position of the driver, who, on the Roval taxicabs is at the back and slightly higher than the top of his cab. Although this is the first time a taxicab of this style has been produced, the idea is not new, this type of chassis having been used for light delivery work for about two years. The feature is that the power plant is above or behind the rear axle. It consists of a single cylinder De Dion Bouton engine rated at 9-horsepower, a very compact three speed transmission, and final drive by side chains.

The frame is special, being of pressed steel with a considerable drop to give a low side entrance, and having the driver's platform stamped out with the side members. The closed body is not only larger than can be fitted to the standard type of taxicab, but it is better suspended by reason of its position midway between the two axles. The front portion, usually occupied by the engine, serves as a platform for the carrying of luggage. The disadvantage of the driver's position appears to be the very complicated and indirect steering linkage made necessary.

The company having taken over this venture has decided to put the cabs into circulation at the same rate of fares as are charged by the horse cab drivers, the initial rate being 15 cents for a distance of practically 1,400 yards. After this distance has been covered the succeeding miles are at a much lower rate.

Roval Taxicab Is an Entirely New Type in Paris

FRENCH SMALL CAR RELIABILITY TRIALS NEXT IN ORDER

PARIS, Nov. 23—Twenty-seven small cars are entered for the first Reliability Trials to be held in France. The small vehicles are to cover fifteen daily stages of 125 miles each at an average speed of 15½ miles an hour without any stoppages other than for tightening nuts, adjusting brakes and driving chains, taking on oil, water and gasoline, cleaning spark plugs or carbureter in case of obstruction, and changing tires. Although these do not count as penalizations, they must be noted by the observers, and will serve to divide the competitors in case of a tie from which a winner cannot otherwise be evolved.

The organizers are convinced that regularity alone will be sufficient to weed out the weaklings, especially as the event has to be run in mid-winter over roads that are never good and are sometimes decidedly bad. The central station will be some garage in Paris, from which the competitors will be sent out each morning to cover one of six courses prepared in advance, but which will not be announced until a few minutes before the start.

By keeping the route to be travelled over in the dark until the hour of starting, it is believed that the possibility of fraud will be altogether eliminated. An observer supplied by a rival firm will be carried on each car, and the technical portion of the test will be under the control of Gustave Caillois, once a Vanderbilt race driver, with Thomas, Paul Meyan, a sporting journalist, and Eugene Renaux, the winner of the Coupe de la Presse.

The cars entered in the Reliability Trials are supplied by the voiturette specialists of France, comprising three each from Sizaire & Naudin, Gregoire, Delage, Barre de Niort, Doriot-Flandrin, Corre La Licorne, Turicum, and Alcyon, and one each from Hurtu, Fouillaron and Zenith. The definition of a small car is one with a single-cylinder engine of not more than 4 9-10 bore by 5 9-10 inches stroke; 3 9-10 by 5 1-10 for two cylinders, and 3 1-10 by 4 7-10 for four cylinders. They must be in every respect according to current catalogue, and completely fitted for touring with mudguards, running boards, hood, windshield and lanterns.

Single-cylinder cars will be slightly in the majority, followed closely by small fours, with a sprinkling of twos. It is not likely that the maximum dimensions allowed under the rules will be taken advantage of, the majority of small cars on the market having engines with slightly less bore and stroke than those allowed. Nothing is to be gained by having the largest possible engine, for no account will be taken of any speeds above 15 1-2 miles an hour average for the entire distance.

LOOKS DOUBTFUL IF FRENCH GRAND PRIX WILL BE HELD

PARIS, Nov. 24—Nine entries have been received towards the 45 necessary before the Automobile Club of France will hold a Grand Prix. As there are less than two weeks in which to obtain the remaining 36, the prospects of the race would appear to be doubtful. The firms already entered are De Dion Bouton, Benz and Rolland-Pilain. The minimum figure is unnecessarily high, for only once has this number of starters been obtained for an international race held in France.

On the Auvergne course in 1905 there were only 29 starters; on the Sarthe in 1906 the number was 34; at Dieppe in 1907 it was 38, and in the following year at the same place it reached the record of 49. Last year, when nobody wanted to race, the number of starters had to be 40; now that there is a certain feeling in favor of a speed event the number has to be 45 before the club will move.

If the Automobile Club of France is rather cold hearted over the prospects of an automobile race, the same does not apply to the Dieppe district. The mayor of the town and the deputy of the district have just paid a visit to the racing board in order to promise a subsidy of $20,000 if the race is held on the triangular course by the seashore. In addition, they will undertake to put the roads in racing trim at an additional cost of about $15,000.

Should an aeroplane race be added to the automobile speed test, the district will come forward with a subsidy of $40.000 in addition to all local assistance for organizing these events.

In a moment of enthusiasm the Club proposed to have two days' automobile racing at Dieppe, two days on which motor boats would show their speed ability in the bay, and two or three days for aeroplane races over a prepared aerodrome, then as a grand final a flight of all the artificial birds across the English Channel to the British shore, a stay there of about half an hour in order to replenish the gasoline and oil supply, and return to the starting point.

The scheme is the most ambitious one ever conceived by the Club. But it was no sooner conceived than they seemed to become afraid of it, as is shown by the fixing of 45 cars as the minimum for the Grand Prix, and the declaration that the aeroplane race will only be held if the automobile event can be carried through. Dieppe, however, is so enthusiastic over the matter that she is capable of carrying all or a portion of the program through without the aid of the club.

Negotiations have already been commenced with Brighton, on the opposite side of the Channel, in order to endeavor to put up a big prize for flights over the sea if the Automobile Club backs out of the affair.

PARIS, Nov. 30—The lists for the proposed revival of the Grand Prix of the Automobile Club of France closed to-day. Insufficient entries were received, and this will mean the abandonment of the race in 1910, unless the club can be persuaded to change its mind.

BUSSING PRINCIPAL WINNER IN AUSTRIAN TRIALS

VIENNA, Nov. 24—Austria's commercial car trials, October 3 to 17, the results of which have just been published, were a great success, as of the fourteen vehicles that started out on the 1,100 kilometers tour, all fourteen returned to Vienna. The judges' awards are somewhat of a triumph for the German industry, as the Büssing cars of Brunswick carried off the chief trophies. The prize of the Ministry of Commerce for the vehicle with the best daily result, went to the Büssing bus, which also received the prize of the Minister of Public Works for the best omnibus. The trophy given by the same department was awarded to the Büssing road-train, which took the gold medal of the Austrian A. C. as well. Two prizes of the Ministry of War went to the Daimler road-train, and the silver medals were awarded to the Büssing bus, Daimler bus, Fiat delivery van, Büssing van, Mulay van, and Büssing trailer, for the best results in the different categories; while all the competitors received diplomas for having ended the journey successfully. The Büssing victory was analogous to that of Saurer in France.

AND NOW A WHITE ONE AND A HALF TON GASOLINE TRUCK

WIDESPREAD interest of late concentrated on the commercial vehicle situation and the existing types of cars, has resulted in several newcomers in that field. Of these, none will excite more surprise than the announcement that the White Company will produce a gasoline-driven truck of 1 1-2 tons nominal capacity. Surprise because this concern has but recently entered the gasoline field, and admiration at the details of the car as turned out, will be intermingled equally.

Rear Construction and Twin Tires on White Gasoline Truck

As the two illustrations on this page show, the conventional lines are followed, the motor being located in front under a hood, driving through a clutch to a transmission in a mid-location, and from there back to the rear wheels by shaft and bevel gears.

In the motor will be noticed a radical departure from the conventional, however, as the block engine of the pleasure car is used. In this the White Company will be one of, if not the first, to use a block motor of four cylinders for commercial purposes.

In detail the engine used in the truck is the standard White gasoline engine with a bore of 3 3-4 inches and a stroke of 5 1-8 inches. The intake and exhaust passages form an integral part of the engine casting. The valve stems and valve springs are completely enclosed. The clutch is of the leather-faced cone type; the transmission has four forward speeds, and the drive from gearcase to rear axle is by means of a shaft. Both the engine and the gearcase are supported in the frame by three-point suspension.

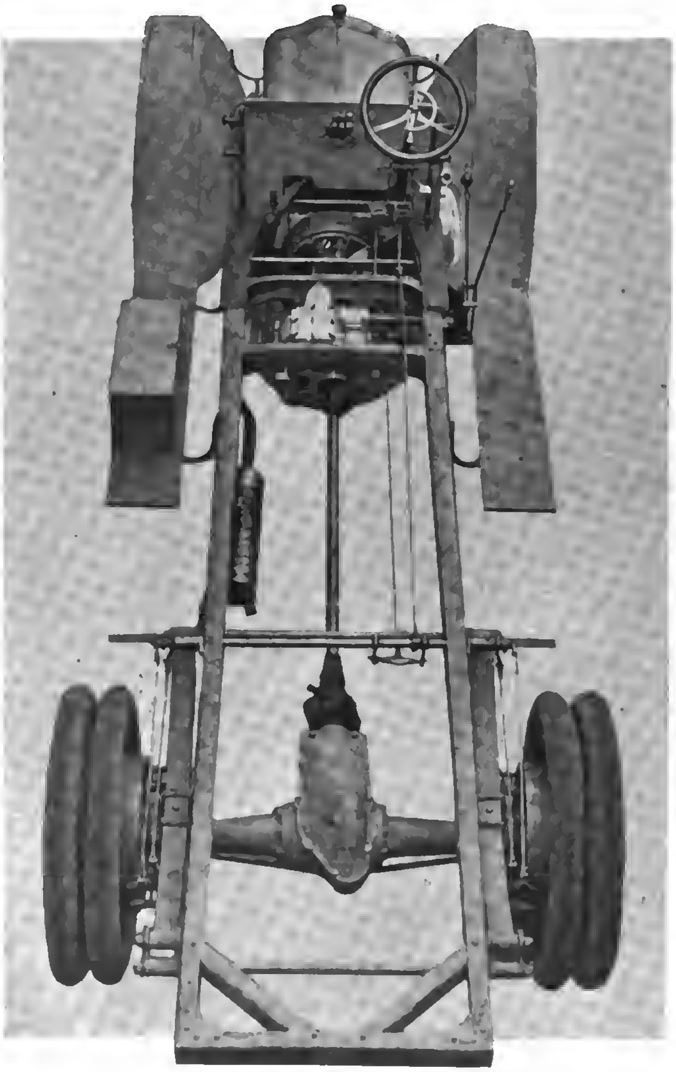
In accordance with recent foreign practice, the truck is fitted with pneumatic tires, each rear wheel being fitted with two 36 by 4 tires. The rear axle is so located that when the truck is loaded practically all of the load is supported by the rear wheels, so that steering is rendered very easy. The wheel base is 144 inches, the ratio between the rate of revolution of the engine and of the rear wheels on the direct drive is 7 to 1. The accompanying illustration of the rear construction shows the liberal dimensions of the brake-drums and the unusually substantial construction of the rear axle, springs, etc.

In particular, the differential housing will be noticed. This is a very neat construction, and withal, a very accessible one. There are but three parts, the two tapering axle sleeves and the gear housing proper. The sleeves are bolted up to the housing by means of integral flanges, while the gears may be reached or seen, for the various purposes of inspection, oiling, repairs, etc., by removing the cover. The latter is held in place by nine bolts, so that its removal is a matter of but a minute's work.

Two sets of brakes are fitted, following touring car practice. These are both located on the rear hubs, and are operated in the usual manner, one by foot pedal and the other by hand lever at the side. The clutch pedal, when pressed clear forward, will pick up the emergency brakes also.

On the order of touring car practice, too, is the frame. This is of pressed steel, of channel section with the open side turned in, so as to present a smooth exterior. The thickness of metal is, however, very considerable, while the bracing at the rear end, where the strains of a truck body would be greatest, is unusually stiff. Not only are the usual gusset plates provided at top and bottom, but a second diagonal bracing is added. This takes the form of a channel of slightly lessened height, bent to a trough shape in the middle of its length. This central part is riveted to the back member of the frame by six stout rivets, while the end portions are flattened to go inside of the side members, where they are riveted in place. In addition to this, the spring support takes the form of a continuous bar, which extends from the outside of one spring eye across the car to the outside of the other spring eye. This at the front and rear of the back springs, which are semi elliptic in shape, strengthens the rear portion of the chassis very materially.

Considering the weight of load in relation to the possible speed, 3,000 pounds moving at not over 16 miles per hour, in comparison with touring car practice, 800 pounds load moving at speeds up to and beyond 40 miles per hour, the use of pneumatic tires is seen to be very reasonably sure of success.



White Chassis From Above, Showing Simplicity of Rear Axle

THINGS RUSSELL HUFF OBSERVED ABROAD

PARIS, Nov. 26—"There is very little that is radically new on the European automobile market," said Russell Huff, chief engineer of the Packard Motor Car Company, to THE AUTOMOBILE representative. Mr. Huff had paid a hurried trip to Europe primarily to visit the London automobile show, and at the same time to look into the European field generally. After a few days in London he made a run of the French factories, slipped over to Belgium, and will sail for New York on the *Lusitania*.

"All the tendency is towards small four-cylinder low-powered cars. The European makers have stopped building large cars altogether. Simplification is being pushed to a very fine degree, the parts being reduced as low as possible in order to make the car cheap to produce in the first case and easy to maintain when in the hands of the private owner. The chain-driven car has almost gone out of business. In England there is a strong tendency towards worm drive, in place of bevel gear. I particularly noticed that there is no boom in six-cylinder cars. I made a list of all the firms having formerly made six-cylinder cars in rather important numbers, and who did not show them this year. There were seven or eight firms who have abandoned the six.

"On the other hand, every firm of importance has brought out a small four-cylinder car, of about 12 to 20 horsepower, and in each case this small model is made the leading line. Where sixes are still shown they are very small engines, as the Delaunay-Belleville and the new Renault. Taking an average, the American engineering standard is quite as high as that of Europe, while in the matter of steels we have got far ahead of the European constructor.

"Business seemed to be good at the London show, and the Britisher was doubtless helped enormously by the absence for the first time of the rival show in Paris. This enabled him to secure a lot of outside contracts that he would never otherwise have got. Both in France and England the commercial vehicle business seems promising. All kinds of firms having any considerable amount of haulage to do have changed from horses to power vehicles. Taxicabs and motor omnibuses have put the horse variety entirely out of business. The European taxicab is a very light vehicle, generally with two cylinders in London, and often with only one cylinder in Paris. It is declared that owing to keen competition not much money is being earned by the London taxicab companies, although the vehicles are popular.

"There is a strong tendency in England towards the adoption of what is known as the torpedo type of automobile body. It is straight-line body, with as little resistance as possible combined with maximum protection against the wind. The cars have high side doors for both front and rear seats, while the seats are set very low to give the passengers full protection. Wire wheels, of the dismountable type, are also a popular feature in England.

"Although business generally seems to be good, the volume of trade is far short of that in the United States. Whereas we at home will doubtless turn out 200,000 cars next year, the estimated product of the combined English factories is only 12,000 cars. When the European buys a car it is generally kept for a number of years. There are scores of cars doing good service in Paris which came out of the factory six or seven years ago. They have had their body work changed from time to time, and often carry closed limousines, and they have been freshly painted when they needed it. Nevertheless, they are old-fashioned models that the American automobilist would be ashamed to drive.

"European touring is as popular as ever among Americans. As an indication, our own Paris branch has been in touch with over two hundred Packard parties during the present season. The transportation companies take care of the automobiles so thoroughly, and the various touring bodies have so simplified the formalities that there is nothing difficult about an automobile trip through Europe. There is a charm about foreign travel that appeals to our people, and will certainly cause them to visit Europe every year in increasing numbers. There are good roads, historic interest, fine scenery, architecture and quaint customs that cannot be seen at home.

"One point of interest to the American visitor is the comparatively small life got out of tires on the hard macadam roads of Europe. I was told in England that 2,500 miles out of a steel-studded non-skid tire was considered very satisfactory service. Being very hard and dust proof, the wear is naturally very much greater than on our softer American roads.

"There does not appear to be much possibility of business with Europe for other than the makers of cheap, popular cars. The market is so small that none of the first-class makers are likely to bother with it. Quite a number of American cars are sold in England, and appear to sell well. Practically none are sold in France. In every case those who have got the business are makers of the cheaper moderate-power cars."

THE AUTOMOBILE CALENDAR

Dec. 25-Jan. 1....Columbus, O., Automobile Show, Columbus Automobile Club.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows' Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South Street.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-26........Kansas City, Mo., Convention Hall, Fouth Annual Automobile Show.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Secretary.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 12-19......Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

WHAT GENERAL MOTORS WILL DO IN DETROIT

DETROIT, Nov. 28—Some day some ambitious chronicler of facts stranger than fiction is going to write the romance of the automobile industry. When he does a little space might profitably be devoted to telling how Detroit finally came into its own, thereby adding another bit of testimony in support of the frayed old adage that all things come to those who wait.

Among those who hailed with acclaim the announcement that the General Motors Company would establish a central plant here, which will be the largest automobile manufactory in the world, few were familiar with a bit of hitherto unwritten history that at this stage of the proceedings makes decidedly interesting reading, although to loyal Detroiters the admission of early error of judgment may be a bit humiliating.

W. C. Durant, of General Motors

Six years ago David D. Buick was building gasoline engines in a little shop out on the west side of the city. He believed the automobile, then in an experimental stage, was facing a great future and decided to get in on the ground floor. He started out to organize an automobile company, but never got past the starting point so far as Detroit capital was concerned. Local men of means were not looking for investments in such hair-brained enterprises as this.

Perhaps their indifference was not strange. In those days they held automobile "races" on the old Grosse Pointe track, and thousands flocked there to witness the antics of the speed merchants with their "benzine buggies" and snail-like electrics that often expired before they succeeded in circling the mile track, and went away with serious doubts as to whether such an unreliable device as an automobile could ever be made practical.

Buick worked in his shop days and spent his nights trying to interest capital, being met with rebuffs on every hand. A few thousand dollars was all he required, and he had enough business in sight to cover the capital he was seeking several times over. About this time Flint, Mich., already famous as the Vehicle City of America, was casting about for new fields to conquer, and thither Buick went, shaking the dust of Detroit from his feet. The Buick Motor Company was organized, and a comfortable business soon established. Then W. C. Durant, who had made a fortune as a manufacturer of carriages and wagons, decided to enter the automobile field, and acquired an interest in the Buick Motor Company. The indefatigable energy and executive ability that had gained for him independence in one line immediately manifested itself in the new field, with the result that the automobile business grew by leaps and bounds. The history of the Buick Motor Company, and how in Mr. Durant's hands it furnished a nucleus for the General Motors Company, is all of such recent date that there is no use reviewing it.

What the Buick Motor Company might have amounted to had Detroiters interested themselves in the enterprise six years ago will never be known. Certainly similar concerns that followed on have exceeded the fondest expectations. However, the point of interest at this time is that without the Buick Motor Company there would probably have been no General Motors Company, and without the General Motors Company there would have been no central plant representing an investment of $2,500,000, and furnishing employment for from five to seven thousand men. It may be a long way around, but there is a certain degree of comfort to Detroiters in knowing that, chiefly because a proposition was turned down cold six years ago, the city's indisputable position as the hub of automobile industry is to be immeasurably strengthened by the addition of the largest plant of its kind in existence.

Details of the central plant for the General Motors Company, whose location in Detroit was announced exclusively in last week's AUTOMOBILE, have been made public, and are on an even more comprehensive scale than was anticipated. Fifty acres of ground has been secured in the northeastern part of the city, and here fourteen mammoth buildings having a total floor space in excess of one hundred acres will be erected. These include, according to the plans prepared:

One administration building, three stories, 90 feet by 296 feet.
One central machine building, with two wings, 90 feet by 256 feet, three stories.
One central pavilion, three stories, 90 feet by 436 feet.
One "saw tooth" section, one story, 206 feet by 256 feet.
One assembling plant, three stories, 90 feet by 1,096 feet.
Two assembling plants, three stories, 90 feet by 700 feet each.
One warehouse, two stories, 263 feet by 290 feet.
One wood shop, three stories, 90 feet by 290 feet.
One wood shop, three stories, 90 feet by 256 feet.
One wood shop, one story, 300 feet by 256 feet.
One paint shop, three stories, 90 feet by 550 feet.
One foundry, one story with monitor roof, 180 feet by 780 feet.
One power house, one story, 90 feet by 150 feet.

In addition there will be many smaller buildings, such as shipping sheds, plant offices, etc. All will be of fireproof construction, and embody the most approved ideas.

The site, which alone cost $300,000, is ideal, extending as it does for several blocks along the railroad, with sidetrack facilities.

At present there are some thirty-five structures of various kinds on the property. These will be torn down or moved as rapidly as possible, and work on the plant proper will begin early in the spring. It is the present intention to have everything in shape for the season of 1911.

Speculation has been rife since the first announcement of the new plant was made as to what effect it would have on the future of other holdings of the General Motors Company. While not caring to go into details at this time further than to state that the new plant will be devoted to the production of a general line of automobiles and parts, those back of the undertaking announce that it will in no way affect the other plants, further than, where deemed necessary, to relieve them of some of their burdens.

Heretofore the General Motors Company has confined its activities to the purchase of interests in other plants. It now holds the immense Cadillac plant in Detroit, the Buick at Flint, one of the largest in the country; Welch, Cartercar, Oakland, and Rapid, at Pontiac; and several others scattered about Michigan, as well as numerous accessory plants. Now it has taken the greatest forward step in its career, and the outcome is of the utmost significance to Detroit and the trade in general.

LEXINGTON SOON WILL BE A HOOSIER

LEXINGTON, KY., Nov. 29—The Lexington Motor Car Company has its fine new brick plant at Connersville, Ind., well under way, the first story being nearly completed. With good building weather such as is the rule at present, the middle of January will see the company comfortably installed. The Lexington plant is to be disposed of at a reasonable figure. The Commercial Club of Connersville has given a liberal bonus in return for the transplanting of the business to that city, and this, together with the footing gained during the past season, should establish the Lexington more firmly than ever both with customers and agents. The company expects to build 400 cars this season, and, like most others in the industry, has its total output already contracted for.

A. A. A. IN ANNUAL MEETING RE-ELECTS PRESIDENT SPEARE

NEW YORK, Dec 1—Placing itself strongly upon record as being unequivocally opposed to reckless and unfair use of the highways by inconsiderate operators of automobiles, the annual meeting of the A. A. A. to-day re-elected Lewis R. Speare to its presidency, expressing unanimous approval of his occupancy of the office during the unexpired portion of the term of William H. Hotchkiss, who resigned to become superintendent of insurance of New York State. This is the official list for the ensuing year:

President, Lewis R. Speare, Massachusetts.
First Vice-President, Robert P. Hooper, Pennsylvania.
Second Vice-President, Frank M. Joyce, Minnesota.
Third Vice-President, F. C. Donald, Illinois.
Treasurer, H. A. Bonnell, New Jersey.
Secretary, Frederick H. Elliott, New York.
Chairman of the Executive Committee—A. G. Batchelder.
Chairman of the Legislative Committee—Charles Thaddeus Terry.
Chairman of the Touring Information Board—Powell Evans.
Chairman of the Contest Board—S. M. Butler.
Chairman of the Good Roads Committee—George C. Diehl.

ADDITIONAL EXECUTIVE COMMITTEE MEMBERS

S. A. Miles	Edwin S. George	William R. Innis
H. O. Smith	Paul C. Wolf	A. D. Converse
Alfred Reeves	Frank G. Webb	A. E. Lerch
W. E. Metzger	J. P. Coglin	G. W. Allen
C. H. Gillette	H. M. Rowe	A. E. Coffin
James T. Drought	F. C. Battey	A. H. Knoll
John Bancroft	J. H. Edwards	
Oliver A. Quayle	Louis W. Hill	

On the first day of the meeting, the opening item was the dissolution of the old stockholding corporation under the New Jersey law, and the substitution of a more flexible charter under the Connecticut statute. The report of Chairman Terry was accepted in its entirety, and the necessary papers were signed by all the directors present at the meeting.

Reports of the various boards indicated that the work of the association has prospered substantially in the past twelvemonth, and the association is in a generally prosperous condition.

Chairman George C. Diehl of the Good Roads board referred to the successful Cleveland convention, and predicted something even more epochal at St. Louis next year.

Chairman Terry of the Legislative board presented a very exhaustive report and outlined the general plan that has been proposed for the First National Legislative convention which will be held in Washington, D. C., next February. At that time the National Registration bill will be re-introduced into Congress and it is expected that a public hearing on the measure will be secured during the week of the convention. The Uniform State motor vehicle law will also be brought prominently before the members and efforts will be made to secure its introduction into the legislature of those States which either possess no effective laws or those which in certain instances have been shown to be unreasonable in their provisions.

Chairman F. B. Hower, of the Contest board, told of the season's contests and indicated unmistakably that he did not desire a reappointment. In recognition of his indefatigable activities, a unanimous resolution of thanks was passed.

Chairman Powell Evans, of the Touring Information board, told of what had been accomplished in this direction and what was being outlined for the future.

Treasurer H. A. Bonnell's report gave a balance of over $12,000 in the treasury.

Secretary F. H. Elliott's figures placed the present membership at 25,759, represented in 30 State associations and 225 clubs. Six new State bodies have been formed during the past year.

Though President Speare, in his report, had referred to the inconsiderate use of the roads by the few, the following resolution, introduced by O. A. Quayle, chairman of the New York State Association legislative committee, was unanimously passed:

"Resolved, That the American Automobile Association places itself upon record as being unalterably opposed to the unfair use of the highways by criminal and lawless operators of motor-driven vehicles, and, furthermore, this national organization of automobile owners calls upon its various State associations to propose and secure the passage of laws which shall rid the highways of reckless and inconsiderate drivers even to the extent of revocation of licenses and jail penalties in proportion to the nature of the offences."

Among the recommendations of President Speare, was one concerning the disposition of the Glidden trophy, which will probably never be competed for again. The consensus of opinion is that the 1910 tour shall be known as the A. A. A. National Endurance Run, with rules so strenuous in character as to prove the undoubted reliability of the contestants, but minus a conclusion which shall positively require a single prize-winner.

It was decided that hereafter the fee for individual members shall be $5, the former price having been $3.

The association's offices will be continued at 437 Fifth avenue, at least for the next two years.

Due recognition was given of the assistance rendered by the National Association of Automobile Manufacturers, in the carrying on of the work of the national organization.

Powell Evans, of the Automobile Club of Philadelphia, desired that the association consider the possibility of extending its activities into the field of aeronautics, which, in its developments, he said, bade fair to be a kindred pastime to automobiling. This was referred to a special committee of which Mr. Evans was made chairman.

The nominating committee, of which J. P. Coghlin of Massachusetts was chairman, made its report at the Wednesday session, and no opposition candidates were placed in nomination.

N. A. A. M. DECEMBER MONTHLY MEETING

It was natural that Chicago show matters should occupy most of the attention of the executive committee of the National Association of Automobile Manufacturers at its monthly meeting held at 7 East Forty-second street Wednesday afternoon. Because of the presence in the city of many members at the meetings of the A. L. A. M. and the A. M. C. M. A., the attendance was much larger than usual.

A. M. C. M. A. HOLDS SPECIAL SESSION

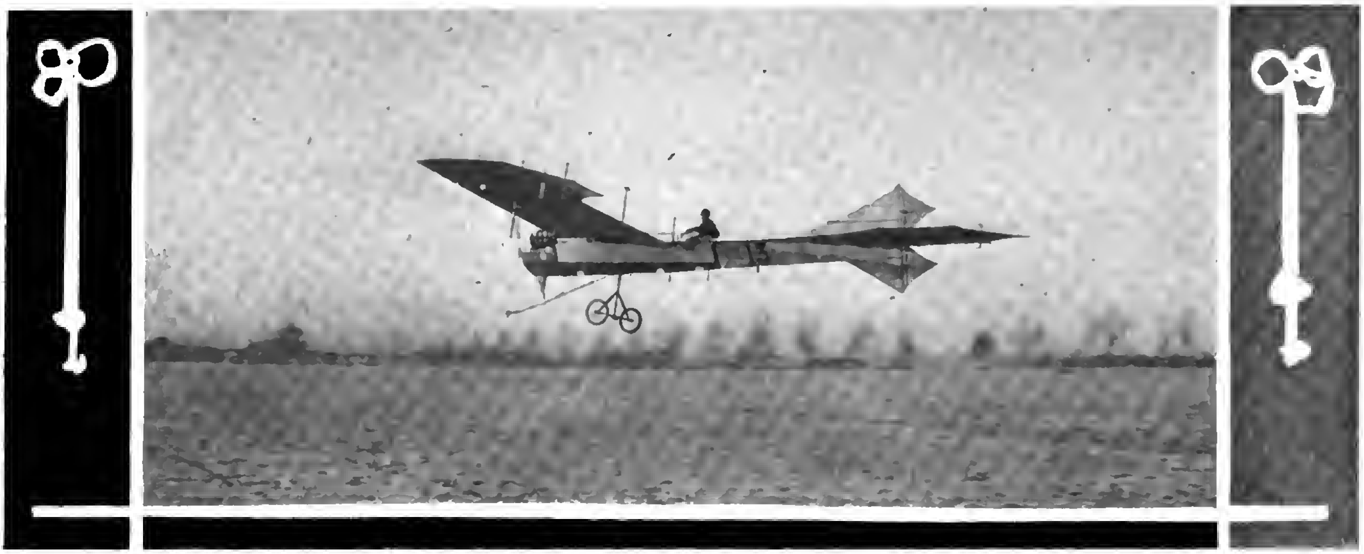
The Committee of Management of the American Motor Car Manufacturers' Association, with Chairman H. O. Smith presiding, held a session Tuesday at the association's headquarters, Fifth avenue and Forty-second street, its time being principally occupied with Grand Central Palace show arrangements. It is also understood that the Selden patent came in for some attention.

A. L. A. M. HOLDS BUSINESS SESSIONS

At its headquarters on East Forty-second street, the Association of Licensed Automobile Manufacturers, Tuesday, held a meeting of all members, with a most generous attendance. President Charles Clifton occupied the chair, as he did at the meeting of the executive committee on Wednesday. No information was forthcoming at the time of going to press, though it was intimated that all the members of the A. M. C. M. A. had been given opportunity to obtain licenses upon reasonable terms.

WRIGHTS ARRANGE DETAILS OF CO.

The officers of the $1,000,000 Wright aeroplane syndicate held a meeting Saturday at the office of Nicoll, Anable, Lindsay & Fuller, 31 Nassau street, New York, at which further details of the organization were perfected. After the meeting the brothers left for Dayton, O.



Küller Flying on an Antoinette Monoplane at Chalons Camp, in the Vicinity of Paris

AEROPLANE SCHOOLS ESTABLISHED IN FRANCE

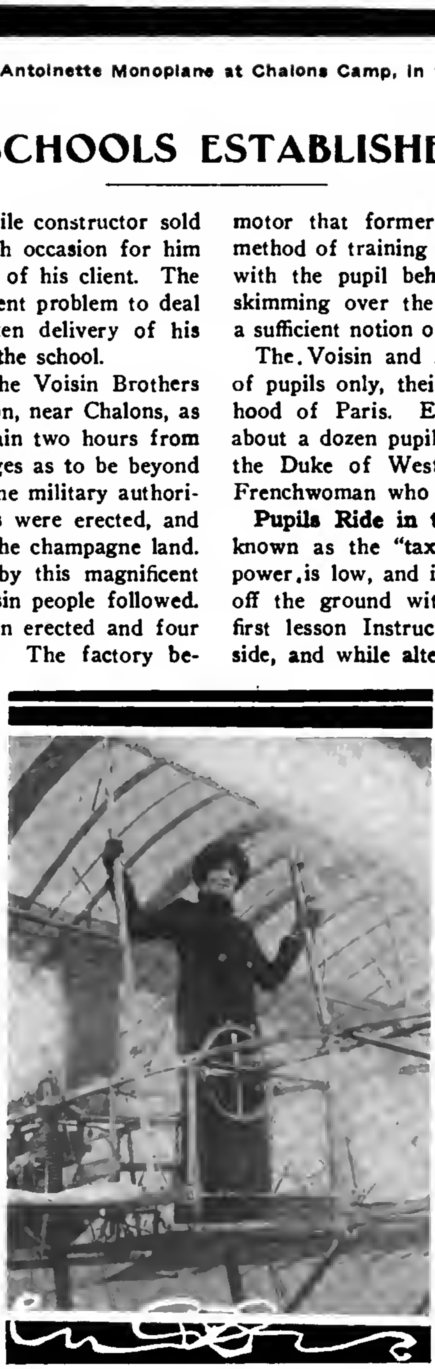
PARIS, Nov. 30—When the early automobile constructor sold a car to a customer there was not much occasion for him to trouble about the experience or otherwise of his client. The early aeroplane constructor has quite a different problem to deal with, for as soon as his customer has taken delivery of his machine he asks to be taught to fly. Hence the school.

When Henry Farman broke away from the Voisin Brothers he pitched on the military camp at Mourmelon, near Chalons, as the future scene of his activities. A vast plain two hours from Paris by rail, but so far removed from villages as to be beyond the reach of crowds, was loaned to him by the military authorities. Adjoining land was bought, workshops were erected, and the first aeroplane school was established in the champagne land. The Antoinette people were next attracted by this magnificent plain, with its surfaces like a lawn; the Voisin people followed.

Within twelve months one factory has been erected and four aeronautical schools brought into existence. The factory belongs to Henry Farman. It consists of four huge wooden sheds, capable of holding a dozen aeroplanes, complete with workshops, offices, sleeping rooms, etc. It is here that all the Farman biplanes are partially built and entirely assembled. The rapid growth of business makes it impossible to build entirely in the shops, and until enlargements can be made much of the wood has to be worked outside and assembled at the Mourmelon factory. The engines are built at the Gnome factory, near Paris, sent to Mourmelon after having been tested, and fitted to the aeroplane. When the machine is ready all that is necessary is to push it out of doors, start the engine and test it over the plain that spreads out for two or three miles.

Farman trains pupils in addition to building flyers. At present he has under his charge, among others, Van den Born, a well-known racing cyclist, and Sir Henry Rawlinson, a retired automobile dealer who was for many years connected with Darracq, and who has fitted his first flyer with a 120-horsepower Darracq motor that formerly did service on a racing car. Farman's method of training is first to test the machine alone, then mount with the pupil behind him. After an hour or two spent in skimming over the ground, the pupil has generally picked up a sufficient notion of the manner in which the levers are worked.

The Voisin and Antoinette companies undertake the training of pupils only, their respective factories being in the neighborhood of Paris. Edouard Chateau, the Voisin instructor, has about a dozen pupils, among them being the English sportsman, the Duke of Westminster, and Madame Delaroche, a young Frenchwoman who is proud of the title of the first lady to fly.



Mme. Delaroche, First Lady to Fly Alone

Pupils Ride in the "Taxi"—There is a special aeroplane, known as the "taxi," on which pupils are taught to fly. Its power is low, and its planes so adjusted that it can only be got off the ground with a certain amount of difficulty. For the first lesson Instructor Chateau mounts with the pupil by his side, and while alternately running over the ground and flying through the air explains the movements to his pupils. Then comes the first flight alone. Starting from the door of the shed, the machine runs up the rising ground without being able to rise into the air. Then the top of the slope is reached, and the downward run commenced. If the aeroplane is handled properly it will fly over the descending ground without any particular effort of the pilot. After covering about a mile, however, the rising ground is again reached, and as the power of the engine has not been sufficient to rise to a great altitude, the wheels touch, and the machine once more runs over the surface. When it is possible to fly round the course in this manner the pupil is sufficiently advanced to take his own machine, equipped with a more powerful motor and adjusted to rise from the sloping ground. Under this method of instruction very little time is lost in repairs. The "taxi" has covered several thousand kilometers, running over the ground and flying in the air in the hands of various pupils, without a single breakage. The time necessary to learn varies considerable, one pupil flying easily after a couple of lessons while another struggles for months. Instructor Chateau finds that the best pupils are automobilists who have had yachting experience. The automobile has made them familiar with high speed, while the gentle movements of the helm on a sailing vessel have prepared them for similar movements with the elevation rudder and warping planes of a flying machine.

For lack of a machine that would carry two, the Antoinette people have until recently been obliged to confine their instruction to theoretical explanations on land, leaving it to the pupil to make the best of his apparatus in the air. As the Antoinette monoplane is not the easiest machine to handle near the ground, there was generally a large amount of work for the repair men, and heavy bills for the pupil. Now a two-passenger machine has been made, on which Hubert Latham can take a pupil and while soaring through the air with him give practical exhibitions of the operation of the levers.

Assembling and repair work form a considerable portion of the activities of the aviation settlement. After the machines have been completely built at the factory, they are taken down to be sent by road or rail to the training school. If they are found defective, the necessary adjustments are made on the spot, a ten-mile demonstration flight is made before the customer, and the bill is ready to be paid. Antoinette in particular is well fitted up for extensive repair work. The big workshops are equipped with power-driven wood-working machinery, and a staff of thirty or forty machinists are constantly employed in this department making the delicately shaped framings for body and wings.

PAULHAN ASCENDS 2,000 FEET IN AEROPLANE

MOURMELON, FRANCE, Nov. 25—An icy breeze was blowing over the open plain when Louis Paulhan, fresh from his triumphs in England, brought out his Farman biplane lightened and equipped for high flying. His object was to beat officially the height record of 360 feet established by Wilbur Wright at Le Mans, exactly eleven months ago. The prize for the performance is offered by Lazare Weiller, the man who bought up the Wright patents in France and formed the French Wright company. Unofficially the Wright record no longer exists, for several aviators have during the year risen to a greater altitude than that attained for the first time by the American champion.

Rising against a wind that blew from 20 to 25 miles an hour, Paulhan quickly left the ground and commenced circles which took him further and further away from the interested groups of spectators. In ten minutes he had risen to a height of 984 feet, thus beating the record allowed to Count de Lambert in his flight over Paris. A few minutes later and the officers in charge of the instruments declared that he had attained a height of 1,181 feet. The machine was a mere speck in the sky, apparently immobile, and so far away that it was impossible to even distinguish the outline of the aviator behind the canvas wind shield.

Then the descent began, gradually at first, and in huge circles, then more rapidly. At 150 feet from the ground Paulhan shut off his motor and glided down in a wide circle, touching earth as lightly as a great bird.

A few minutes after the Farman champion had landed Hubert Latham soared away on his big Antoinette monoplane. He was not officially engaged for the height prize, and no official credit would be given him for whatever he might do. As the general in charge of the Chalons camp was supervising the work of the officers at the recording instruments, Latham did not wish to loose the opportunity of ascertaining exactly how high he could rise. Up and up he soared, until the graceful shape of the bird-like machine could no longer be appreciated, and the open exhaust of the eight-cylinder motor had become muffled in the distance. At the end of ten minutes the officers in charge gave the height as 1,345 feet, thus beating the record of Paulhan, and probably rising higher than any other aviators with the exception of Count de Lambert and Orville Wright. When Count de Lambert flew over the Eiffel Tower it was believed that he had a clearance of 300 feet. As this could not be certified, however, the Aero Club decided to allow him only the height of the tower, which is 984 feet. Experts are of the opinion, however, that the actual height was not less than 1,300 feet.

When Wilbur Wright made his height performance less than a year ago the world was amazed, looking upon the affair as the acme of imprudence. Now altitude has been conquered. Louis Paulhan declares that there is nothing whatever to prevent an aeroplane mounting to an altitude of one mile and remaining there for a considerable length of time. So long as he is sure of his motor the height can be readily attained, and even in case of a stoppage there is less danger with a good machine at a great height than near the ground.

With the Farman machine that had made the official height record, Louis Paulhan came out on the following day with other records in view. The small gasoline tank had been replaced for the big one used for long distance flights; and the lubricating oil tank, which, by the way, contains pure castor oil, was also of the largest size. The Gnome motor, excellent in every other respect, has the defect of being a rather voracious drinker of castor oil, with the result that the tank has to be of much larger size than is generally thought necessary for an engine of such power as this.

The objective point was the military town of Chalons, sixteen miles away to the southeast. But before making the long distance trip Paulhan gave an exhibition of high flying that entirely eclipsed his rival Latham and amazed the spectators. With a breeze behind the aeroplane quickly soared in the direction of Mourmelon-le-Grand, a couple of miles away. At a height of 600 feet Paulhan passed directly over his own hotel, in the center of the village, by the side of the church. Still he rose higher, until the aeroplane was a mere speck in the sky, that had to be watched very closely in order to be kept in view. According to the military officers the height attained was between 1,900 and 2,000 feet, heights which had never previously been attained except by spherical balloons. A landing was made in excellent style, then there was an interval of an hour during which the aeroplane was verified and the aviator and his friends partook of a hasty luncheon.

Soon after noon the Farman biplane was off again, Louis Paulhan at the wheel, and Henry Farman following with a few friends in a fast automobile. Aided by the wind the flying machine traveled rapidly in the direction of the town of Chalons. His height was about 700 feet, which was sufficient to get over all natural obstacles on the route. Farman's last words were that Paulhan should watch the hill outside the town of Chalons, which was much higher than might be supposed. Even in a 60-horsepower automobile, traveling over perfect roads, it was impossible to keep pace with the aeroplane. For a time it was lost to view. Then as Chalons came into sight it was seen once more making a round of the city. Paulhan described a complete circle of the town in full view of the large civil and still larger military population.

Then he commenced the return journey, sixteen miles in a straight line. But the wind was now dead ahead, with the result that it was impossible to make a straight line for the sheds on the Mourmelon plain. The task of the automobile was an easy one, so easy in fact that it got ahead of the aeroplane, which was tacking like a yacht working to windward. When at last he got over the plain Paulhan shut off his motor at a height of 700 feet and glided down to where Farman and the mechanics were awaiting him.

ROADS BUILDING NEWS FROM ALL OVER THE COUNTRY

MACADAM PAVING MAY BE DISCARDED BY JERSEY

TRENTON, N. J., Nov. 29—So great is the stress on the road surface or "metal" as the English call it, brought about by traffic consisting of automobiles only, that macadam has been found to be unequal to it. New Jersey has always ranked in the forefront of good roads States, not alone in advocating them, but also, in actually building and maintaining them when built.

It was indeed, this latter trait which caused Col. Frederick Gilkyson, State road commissioner, to decide that macadam would not stand up under automobile traffic as well as bituminous pavement, and that New Jersey will accordingly change her road-building methods.

This decision has been reached after much inquiry and many experiments which also have demonstrated that pavements superior to the ordinary asphalt may be laid in cities and suburban districts at from $1.15 to $1.50 per square yard, where they now cost from $1.90 to $2.50 per square yard. These are known as bituminous pavements.

The State has eighty-five miles of bituminous pavement at the present time, and specifications have been prepared for thirteen miles more. In this connection New Jersey leads the world. Colonel Gilkyson is now moving in connection with the federal authorities at Washington to bring about the formation of a paving commission to supervise this method of road building, thus avoiding conflicts with any of the patented compounds.

In this way, open bidding will be possible and the cost will be lessened. The bituminous road method is practically dustless, noiseless and rainproof, and at the same time wears well under all kinds of traffic.

FINALLY KENTUCKY WILL HAVE GOOD ROADS

LOUISVILLE, Ky., Nov. 29—Waiting until the last moment to make official denial of its frequently reported and greatly exaggerated decease, the Bosworth-Wyatt good roads amendment to the Kentucky Constitution carried by a majority of 5,490. The amendment, which provides for raising the necessary funds by the removal of constitutional obstacles is worth all of the uncertainty and needless regret of the past three weeks. Its adoption puts Kentucky fifteen years ahead of other southern States and is one of the most advanced steps of any of the others in the direction of substantial road improvement.

The counties in the central and mountain sections showed majorities for the proposition while those in the western portion showed majorities against it as a rule. The result was a great surprise even to Senator Thomas Wyatt, who had introduced the bill, providing for a vote on the amendment. He had hoped that the official tabulation would show a majority for the proposition, but even he did not expect that the majority would be so large.

Senator Joseph F. Bosworth, of Middlesboro, who was one of the authors and strongest champions of the good roads amendment, has publicly expressed his thanks to all friends who had so ably supported the measure. This, he said, would put Kentucky in line with sister States to the north. The amendment, he said, when fully understood by the farmers, would bring hearty thanks and support from them. The editorial obituaries written within the past two weeks, the chiding of Kentuckians for their lack of intelligent self-interest, and the resolutions announced by the press of the State to continue the fight until success was won, turn out to be nothing but practical jokes.

It is expected that a number of counties, particularly those which showed majorities for the bill, will at once set about to take advantage of its provisions.

SECRETARY OF AGRICULTURE REPORTS ON ROADS

WASHINGTON, D. C., Nov. 29—There is much of interest to motorists in the annual report of the Secretary of Agriculture submitted this week to President Taft. It is set forth that proper construction and maintenance of public highways engages public and official attention to a great extent, and the Office of Public Roads has proved its usefulness to the general public more emphatically than ever before. The adoption of State aid in the construction of public roads by more than half the States and the consideration of the question by the remainder, together with large bond issues by many counties, are indexes of the general interest being shown in the work, and have occasioned a great demand upon the office for advice and assistance. These have been given to the fullest extent compatible with the resources of the office, and have brought about more active cooperation and larger material results than ever before.

During the past year especial attention has been given to object lesson work. The purpose of these object-lesson roads was to give elementary instruction to local road builders and to demonstrate the possibilities of road improvement. The policy of the Department in this work leads neither to extremes of conservatism nor radicalism, but toward pointing out the most profitable use of material and means at hand in a given locality.

Second in importance only to object-lesson work is the experimental work of the office. The most important problem considered has been that of preventing the destructive action of automobile traffic on costly macadam roads. In working out this problem experiments have been made to secure satisfactory binders and dust preventives within reasonable cost. Excellent results have been attained in the use of asphalt, tar and other bituminous binders, waste from sugar refineries and wood pulp mills, and other by-products. It was largely to consider this question that the greatest road convention ever held was convened at Paris, in which 29 countries participated, the Director of the Office of Public Roads being chairman of the commission of three representing the United States.

PRIZES AWARDED FOR COMMENDABLE HIGHWAYS

NEW YORK, Nov. 29—By far the most practical and enduring outcome of the recent New York-Atlanta good roads tour lies in the awarding of the prizes for commendable roads as found in the territory met with. That is, not the prizes nor the awarding of them, but the roads which warranted the awarding of prizes, are the real practical benefit derived therefrom.

From New York to Atlanta, 41 counties were passed through. Two series of prizes were awarded to the counties, which should have made the roads through their counties in the best condition at the time of the tour. One series of three prizes amounting to $1,750 was offered by the New York *Herald* to the counties north of Roanoke, Va. Another series of three of the same amount was offered by the Atlanta *Journal* to the counties south of Roanoke. In addition to this, cash to the amount of $500 in the form of three prizes was offered by the Southern Bell Telephone Company, for road prizes to be awarded at the discretion of the judges in the territory south of the State boundary between Virginia and North Carolina, through which this company operates.

Awarding of the prizes was in the hands of a committee of three, composed of A. L. Westgard of the Touring Club of America; J. H. Pratt, State Geologist of North Carolina, and C. H. Hoyt, superintendent of road construction in the office of the United States bureau of good roads. This committee has just announced its verdict, which will be received with much enthusiasm in the South, but one prize going north of Mason's and Dixon's line. The awards were:

New York Herald Prizes

First, $1,000, to Mercer county, N. J., for general excellent conditions of its roads, maintenance and bituminous macadam.

Second, $500, to Jefferson county, W. Va., for macadam pike throughout the county and having abolished the toll system. The State of West Virginia has during the present year organized a State Highway Department, upon which much responsibility rests, and is entitled to loyal support.

Third, $250, to Rockbridge county, Va., for its notable improvement of earth roads.

Atlanta Journal Prizes

First, $1,000, to Guilford county, N. C., for wide, well-graded road and macadam in first-class condition.

Second, $500, to Spartanburg county, N. C., for its notable improvement of all its roads through the county.

Third, $250, to Henry county, Va., for the excellent condition of its earth roads.

Southern Bell Telephone Company's Prizes

First, $250, Greenville county, S. C., for its notable improvement of its highways throughout the county.

Second, $150, to Bessemer City Township, Gaston county, S. C., for relocating and grading road over mountain.

Third, $100, to DeKalb county, Ga., for the interest shown and improvement made in its roads throughout the county.

In reaching the above decisions, the committee took into account seven features of road construction, as follows:

(a) Alignment.
(b) Grading.
(c) Width of roadway between ditches.
(d) Width of roadway surfacing.
(e) Condition of surfacing.
(f) Slope of shoulders and condition of ditches.
(g) General appearance of roadside.

On the basis of the seven points, the awarding of first place to the roads of Mercer County, N. J., with special mention of the work done there in resurfacing the present macadam and of the laying of bituminous macadam, the latest type of automobile road construction, is or should be cheering to the Jersey road commission, which has just decided to abandon all other forms of road in favor of the newer bituminous macadam.

DISGRACEFUL CONTROVERSY OVER BERLIN TURNPIKE

Hartford, Conn., Nov. 29—The much-mooted Berlin turnpike is once again in the limelight and the situation to say the least is farcical. It will be recalled that the latter part of October this seven-mile stretch was formally opened by the Connecticut State highway commissioner, James H. MacDonald. The Automobile Club of Hartford jumped in and organized a sociability run for which various prizes were offered and in the evening, the most pretentious banquet ever held by the Automobile Club of Hartford was given at the Allyn House where the club quarters are located. The highway commissioner was the chief guest of honor. But so far so good.

Shortly after the formal opening of the road and the lauding of the commissioner, there were numerous complaints of the apparent poor condition of the new road, which was constructed by three different contractors, including one from Massachusetts. Now, then, although the commissioner opened up the road he has not yet accepted it in behalf of the State and the contractors were not, of course, paid for their labors.

One contractor, being well aware of the stress subjected by motor cars, asked that the road be oiled or tarred at his own expense, but the State highway commission did not grant the necessary permission so to do, at least this is the story said to have been told by the contractor himself to a newspaper man. The road has not apparently stood up under traffic in the manner that it should, and has been the chief topic of motordom for some time past.

The climax was reached, however, when one of the contractors who built the Hartford end of the road closed up the Hartford terminus by dragging large wagons filled with stone across it. The contractors have had to make such repairs as were necessary before acceptance by the State, at their own expense. The coming of the rain and snow moved the contractor to a decisive end and he blocked off the Hartford terminus so that further damage could not be done to the road at his expense. It was the contractor's intention to thus close the road until the commissioner had accepted it. Users of the highway, however, would not stand for this and the wagons were hauled off the road, and now it promises to be a merry war between the contractor, the commissioner, and the general public.

DEATH OF W. F. FULLER, OF CONNECTICUT

Hartford, Conn., Nov. 27—William F. Fuller, president of the Connecticut Automobile Association, and former president of the Automobile Club of Hartford, died of heart trouble at his home in this city this morning, after a lingering illness. Mr. Fuller was first taken ill last May.

In William F. Fuller the automobilists of Connecticut lost a champion who was ever zealous to further the interests of the sport and the industry. He was president of the Automobile Club of Hartford for two terms, holding that office until the last election, when he stepped down in favor of General Wallace T. Fenn, the present incumbent. He was re-elected president of the Connecticut Automobile Association at the last election. The Automobile Club of Hartford during his régime was marked by a rapid growth in both membership and influence.

Although his death was not unexpected, it nevertheless came as a shock to his many friends. His wife and two children survive him. Mr. Fuller was engaged in the leaf tobacco business with his uncle, under the firm name of E. A. & W. F. Fuller.

ORGANIZATION OF NEW BAY STATE CLUB

Greenfield, Mass., Nov. 27—The Franklin County Automobile Association has been organized, with an initial membership of one hundred. Its principal work will be agitation for the improvement of the roads in Franklin County. Rev. C. W. Merriam is president; Dr. J. C. O'Brien, vice-president; Dr. E. L. Major, secretary, and A. B. Allen, treasurer.

BUFFALONIANS FORM AN AERO CLUB

Buffalo, N. Y., Nov. 30—The Aero Club of Buffalo was launched this week at the Automobile Club of Buffalo's quarters. The officers are John M. Satterfield, president; H. A. Meldrum, Howard A. Forman and Robert K. Root, vice-presidents; George P. Urban, treasurer, and Dai H. Lewis, secretary. The board of directors includes the officers and E. R. Thomas, James How, George Bleistein and Ralph H. Sidway.

The club will be incorporated as soon as the necessary papers can be made out. The membership will be limited to 500, and the dues will be fixed at $5 a year. The initial membership is fifty.

The constitution will provide that the membership shall be composed wholly or in part of persons owning aeronautic inventions for personal or private use, and that it shall be the object of the club to encourage aerial navigation by promoting excursions, races, congresses and expositions. The meetings will be held for the present in the rooms of the automobile club.

SIGN POSTS ERECTED NEAR BALTIMORE

Baltimore, Nov. 29—The Automobile Club of Maryland is making rapid progress in the erection of sign posts along the roads leading from the city. Already many of the signs are in position along the Edmondson avenue pike, the Aanapolis pike and Belair road. The club has appointed J. B. Hutchinson as assistant secretary to Secretary Frank Darling.

Some Pertinent Hints on Adjustment and Care

By Stillman Taylor

WHEN a car is not running smoothly and powerfully, as every well-cared for automobile should do, something is wrong, and the driver should lose no time in tracing the car's indisposition to the probable cause. To diagnose accurately the list of possible troubles and their causes which may befall the several parts of an automobile, is a matter demanding considerable experience, but as the most prevalent troubles are common ones and not difficult to remedy when once located, the average driver who has even an ordinary amount of "gumption" should meet with no difficulty in setting things right when the nature of the failure is made clear to him.

Some of these troubles are, of course, impossible for the driver to repair, and require the services of a good mechanic with a well-equipped machine shop at his disposal. Others are more in the nature of a complete breakdown, which concern a very badly worn, bent, or broken part, and these difficulties are best solved by replacing the defective part with a new one ordered from the factory or the nearest agency. Such failures are naturally outside the scope of this article, which is only written with the idea of assisting the inexperienced driver to first locate the seat of trouble, and then to "tinker up" the offending part.

Importance of Bearing Adjustment and Care—Owing to the important duty which the bearings are called upon to perform, it is very necessary that these vital points should be given a periodical examination with a view of ascertaining the exact condition of the surfaces. Friction in a bearing implies wear and loss of power, and a machine cannot run at its best unless this adhesion and rubbing contact is eliminated as far as possible. This can only be secured by keeping the bearings clean, properly adjusted, and well lubricated.

Cleanliness is of the utmost importance, and if any dirt or other hard particles work into the bearing surfaces, no amount of oil will keep the bearing from cutting and rapid wear. Grit or other hard foreign substance on the rubbing surface will be certain to injure the polished metal of the bearing, and if cleaning is neglected, the surfaces will become rough and the metal badly scratched and scored. If this is found to be the case, it will be necessary to scrape and refit both the bearing and its shaft. This is a job which few amateurs care to attempt, as it is a phase of overhauling demanding experience and good workmanship to insure a good fit.

Looseness in a plain journal bearing is easily taken up by removing the brasses, and carefully scraping their faces until sufficient metal has been removed to make them fit more snugly. A plain bearing should be invariably adjusted to a snug fit, as any appreciable looseness will result in a continuous "knocking" in the cylinder. It is a good plan, however, to set up the crankpin and connecting-rod bearings with just a slight amount of side play, and a good mechanic will generally allow some 1-16-inches play in the engine bearings, that the required degree of flexibility may be secured.

Ball bearings are practically immune from trouble if ordinary care is taken, but a ball may break occasionally, and when this occurs an entire new set of balls should be inserted. If the grooved annular rings, or ball races, show any considerable wear, the whole bearing—rings, separator and balls—should be replaced with new. This is always the best plan, as the life of a ball bearing and its efficiency in reducing friction depends altogether upon the uniformity of the balls. In fact, the balls must be of the same size, as a very small difference in their diameter will tend to prevent them from rotating freely, and rapid wear of balls and races will result. It is very necessary that ball and roller bearings be kept clean and given ample lubrication, and if this is consistently attended to the bearings will perform their functions without trouble, and with maximum life.

The bearings of the transmission or change-speed gears, in particular, should be given good care. These gears are generally given hard usage, and more or less friction of their edges is unavoidable even if the gears are thrown in with a fairly skillful hand. Improper gear changing will, on the other hand, bring excessive wear on the gears, and this constant grinding of their edges before they finally mesh, will quickly wear off particles of metal which, being carried to the bearings by the lubricant, will have a marked tendency to cut and rough the bearings. It is desirable for this reason frequently to drain off the old oil from the gear case, and wash it out thoroughly with kerosene.

Cylinder and Piston Troubles—Although the cylinders should not as a general thing require much attention other than keeping them clean and well lubricated, there are nevertheless a goodly number of cylinder troubles which are primarly causd by carelessness on the part of the driver. A cracked water jacket is not a common trouble, although most garage men have a dozen or so burst jackets to repair every year. A fractured jacket may be caused by the water freezing and bursting the walls as it expands; or it may be caused by filling up the water-circulating system in the mistaken endeavor to cool off the motor when it has been allowed to become overheated. Both of these troubles may be easily avoided if proper care and attention is given the car while in operation, and troubles of this kind seldom, if ever, occur to a car driven by one who is particular and methodical in caring for his machine.

It may seem superfluous to warn the autoist that the water should not be allowed to freeze in the pump or pipes of the circulating system, yet many cars are laid up every winter through neglect in following what should be obvious to the most inexperienced tyro. Freezing may be avoided either by emptying the entire water-cooling system, by heating the garage above the freezing temperature, or by adding glycerine, calcium chloride, or some other anti-freezing agent to the water before it is poured into the radiator. When draining off the water, particular care should be taken to remove the filling cap of the radiator, and to open all the water cocks, not forgetting the drain cock on the under side of the circulating pump. When the pump or the connecting pipes have become frozen, they must be thawed out before an attempt is made to start the motor.

In the case of excessive overheating, cold water should not on any account be poured over the cylinders to reduce their high temperature, neither should cold water be poured into the radiator. If this is done, the rapid contraction of the metal will be almost certain to start a crack, which may be simply a fracture in the outside water jacket, or result in a rupture running through the cylinder wall.

Stopping Water-Jacket Leaks—A small exterior crack in the water jacket may be satisfactorily patched up by filling the aperture with one of the several iron cements sold for this purpose. A fracture of the inside walls can only be repaired by means of the autogenous welding, or other patent brazing process, which is, of course, a machine-shop repair.

Although a porous or spongy cylinder casting is rarely met with on any standard grade car, defects of this kind are occasionally met with in a few of the cheaper machines. In a porous casting, the minute holes—technically termed blowholes—will produce slight leakage, and moisture or sweat will gather on the outside of the defective cylinder when the motor is running. A leak of this nature may be permanently repaired by stopping up the outlet opening and filling the water jacket with a strong solution of salammoniac. Allow the solution to stand in the jacket for some forty-eight hours, then empty and rinse out with cold water. This strong alkali solution will form a rusty deposit on the inside walls, which will fill up the small holes and effectually prevent further leakage.

Ample lubrication of the cylinder walls is very important, as lack of lubrication may result in seizing of the piston, which being dry will score and roughen the cylinder walls. A loose-fitting piston pin will also score and scratch the bore, by working out sufficiently to rub against the walls. As a loose piston or wrist pin will produce "knocking" in the cylinder, this matter should be located and attended to at the first sign of trouble. If the cylinder has become badly scored, its compression will be poor, and the only remedy is to put in a new cylinder or to rebore the damaged one and fit a larger piston. As a new cylinder will cost anywhere from fifty to eighty-five dollars, and as reboring can only be done on a single-cylinder car, and requires expert labor at so much per hour, the proverbial "ounce of prevention" is an axiom well worth remembering.

Kerosene Is Good for Pistons—The pistons should give little if any trouble providing they are kept free of carbon and given proper lubrication. Many careful drivers make it a point to inject a small quantity of kerosene through the compression cock of each cylinder at weekly intervals, and by so doing prevent the accumulation of any considerable deposits of carbonized oil. This is an excellent plan, but it will, of course, thin the lubricating oil in the crankcase, and when this is done the sump should be drained off and replenished with fresh oil at least once a month. Before refilling the crankcase, it is a good plan to fill up the cylinders with kerosene and let them stand overnight—or a couple of days, if the car is idle—then drain off and refill with fresh oil to the required level.

Poor compression is frequently caused by worn piston rings, or rings which have worked around in their grooves until the joints are nearly in line, thus opening up a passage for the escape of the gas. In cases of this kind the cylinder should be removed and the piston rings closely examined. If the gas is escaping past the rings, a sooty mark across their faces will point out where the loss is occuring. That a reasonably high compression may be secured, the joints of the piston rings should be broken; that is, the joint or slot of each ring should be given a quarter turn away from the joint of the other ring. To avoid their shifting about, many makers are pegging the piston rings in their grooves, thus doing away with any possibility of the slots coming into line.

When a loud thumping knock develops in the crankcase of the motor, it may be taken as a pretty infallible indication that either the timing is faulty, or that the mixture is prematurely ignited. Excessive spark advance will start "knocking," and the same noise will be heard and felt if the high gear is kept in too long when taking a stiffish grade. Although the connecting rods and crankshaft are not easily broken, these severe internal strains and stresses are bad for the motor. Indeed, there is really no excuse for trouble of this kind, as it is mainly due to carelessness and downright abuse of the car, of which not even the novice should be found guilty. To start a car by racing the motor and throwing in the clutch with a bang, is a piece of foolishness only sanctioned by racing drivers, who must get speed at any cost. The average driver should not endeavor to emulate this spectacular professional manner of starting his car, but should stick to common-sense methods.

Choked Muffler and Exhaust Pipe—Muffler troubles are not so common as one would suppose, considering that comparatively few autoists seem to think that this part of the car ever is in need of attention. Although unimportant, compared to the other units of the machine, this end of the power plant should not be allowed to become choked up with soot. Explosions in the muffler—due to improper ignition and poor carburetor adjustment—should be avoided so far as possible, as this after firing subjects the muffler to considerable strain, and may even result in a rupture of the muffler walls. When the car is given an overhauling, the muffler and the exhaust piping should be removed, taken apart and thoroughly cleaned. When the baffle plates or silencer pipes are allowed to become encrusted with carbonized oil, a considerable amount of back pressure will result, and while this retardation of the exploded gases will soften the noise of the exhaust, the motor will show a marked loss of power.

Steering Gear Should Not Be Neglected—The steering gear is one of the most important units of the car, and the failure of this mechanism at a critical moment has been the cause of many serious accidents. Although accidents may occur through the sudden breaking of a defective part, mishaps of this character are more apt to be traced to neglect on the driver's part than to a flaw in the material. Ample lubrication is one of the chief requisites, and a little oil will contribute much to secure smooth and easy action of the control mechanism. Any appreciable amount of backlash or side play should be taken up as soon as the trouble is detected, and the adjusting nuts should be tightened up until the front wheels instantly respond to the motion of the steering wheel. The steering rods and levers should not be neglected, and if backlash is present, the matter demands immediate attention.

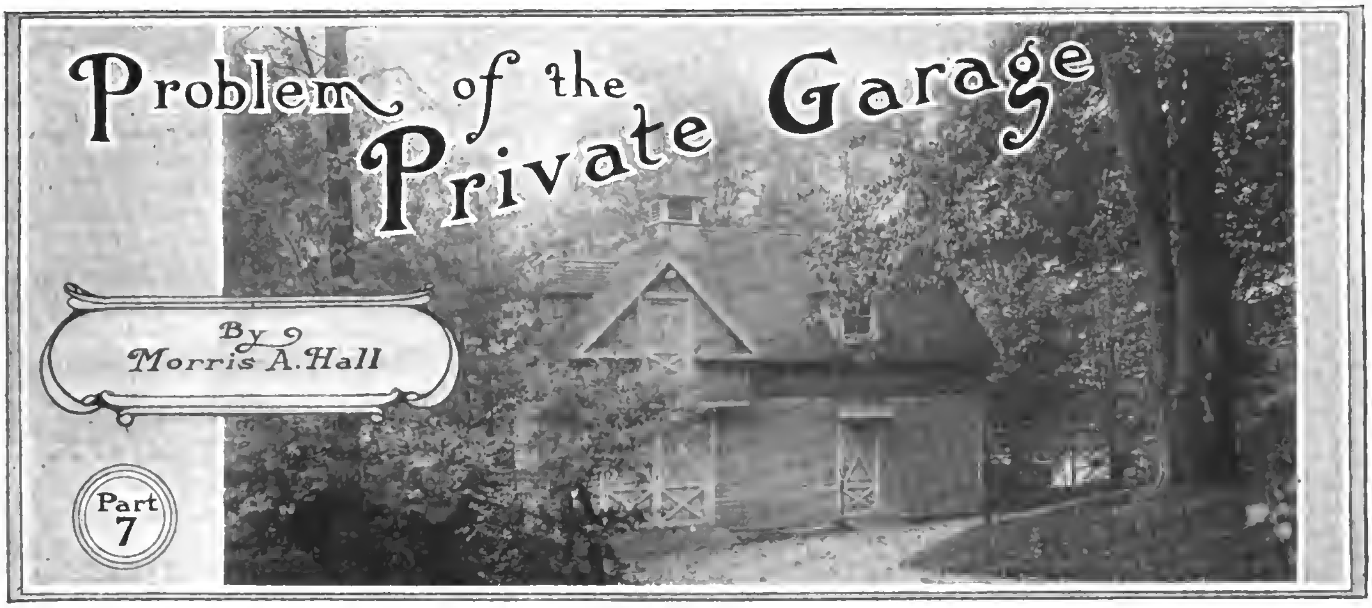
In the case of a ball joint, it may happen that the ball is considerably worn, and if this is found to be the case, it should be replaced. When pins are used, it will be found that they have worn too small for their holes, and the insertion of new pins of slightly larger diameter will solve the trouble. The swivel pins of the steering heads may likewise need adjusting, and any play in this part may be located by rocking the car to one side. Backlash may be also frequently traced to a loose wheel bearing, which may be due to a broken or badly worn ball or race, or it may require nothing more than adjusting. The wheels should rotate freely and the adjusting cones and lock nuts should be only screwed up sufficiently to prevent side play, but not so tight as to bring strain on the balls, which are easily broken.

Some Common Clutch Troubles—The clutch is a much-used member of the car and should upon this account be given a certain share of attention. If the motor speeds up and races and the car runs slowly, it is a sure sign that the clutch is slipping, and this characteristic symptom indicates grease or oil on the leather face, or a weak clutch spring. If oil is the trouble, a little gasoline injected between the two members of the cone will cure the trouble. In case the clutch spring is weak, the tension should be increased by removing the set screw and adjusting the clutch spring by means of the adjusting nut provided for that purpose.

Slipping may also be caused by a dry and hard clutch leather, but a leather in this condition will generally "bite" and take hold so suddenly that the driver will have no difficulty in tracing the trouble to the proper source. Of course, the leather should not be allowed to become hard and stiff, but given an occasional dressing of castor or neatsfoot oil. If this is done at regular intervals, only a small quantity of oil will be required to keep the leather in good shape. For best clutch results the leather should be soft and pliable, but not spongy.

A fierce gripping cone clutch may also be caused by the leather wearing down so as to expose the rivets with which it is fastened. In cases of this kind an examination may find the leather face badly worn, in which event a new leather should be riveted in place. If the leather is found to be in fairly good condition, the rivets should be reset about 1-16 of an inch below the face of the leather.

Clutches of the plate or multiple-disc type generally work in oil and seldom give trouble if supplied with sufficient oil. The old oil should be drained off about once a month, the clutch washed out with kerosene, and fresh oil put in. Many disc clutches consist of a number of cork-faced bronze discs running between steel discs, and through wearing down of the cork inserts, the clutch pedal may work backward until it rests against the slot in the flooring. When this occurs the clutch will slip and fail to hold properly, and the lever should be readjusted. A slipping disc clutch should be attended to at once, as it is likely to burn out and the plates seize or stick together.



Tarrytown Garage on Historic Ground. In 1781, the First Continental Brigade Held a Line of Intrenchments on This Site

BEYOND the advantages which go with the solid concrete garage, that is comparatively solid, there is much to say for the structure built from some other material and surfaced with cement. This kind of building, when properly built has all of the advantages of the all-concrete, designated above as solid, and supposedly many more. Thus, the house of hollow tile, either terra cotta or other material, properly surfaced is said to be warmer in winter and cooler in summer, besides being more dry at all times, less liable to settle on account of lessened weight, and this, too, at practically the same cost.

Hollow tile making has advanced rapidly in the past five years under the stimulus of much building, so that it is now possible to obtain these in a variety of shapes and sizes. This enables the selection of the proper one for the work in question. In this way, it is now possible to obtain not only special corners, special lintel and sill tiles, but also, specially dove-tailed blocks. The function of the dovetail is to hold the cement or stucco in place.

More Concrete Examples—Before going into this hollow tile form to any great extent, perhaps it will be best to conclude the concrete chapter, that is, the all-concrete or solid construction as distinguished from the form in which the cement is but a surface covering, a coat of thick paint as it were. The function of a protective covering renders the cement a minor quantity in the reckoning, reducing its importance very materially. In fact, making it so small as to be insignificant, or at least, not worthy of consideration in an article of this scope.

Elsewhere on this page is shown (through the courtesy of *Motor*) a concrete garage, as planned for three cars. The scope of this house is a very wide one, showing that the question of money did not enter into its design or equipment.

Three-Car Concrete Garage With Full Equipment

In size, the inside dimensions are 38 feet wide by 23 feet deep. But both of these are reduced by the large array of tools around the walls, the width, perhaps more than the depth, since in the former there are tools or closets along two sides, the size of which must be subtracted, while as to the latter, those along the back only need consideration.

As the tools provided are very complete, more so than any one man would undertake to propel through his own efforts, a source of power must be provided. If electric power had been available for lighting, all of the tools might have been driven from a motor, which in turn was supplied with motive power from the lighting wires.

This was not the case, however, so a gasoline motor was provided, of the vertical type to save floor space, and located close to the tools to be driven. The latter include a power hack saw, a lathe, drill press, emery wheel, and dynamo to supply light. In addition to these tools, there is a very large work-bench, a forge for doing light forging or bending, a heater to keep the place warm in winter, and storage for oil, waste, gasoline, clothing, small tools, and supplies. The gas engine for power may be used to help out on the heating, the jacket water being furnished the heater or piped around the building separately. If it had been desired to utilize this to the full extent, the exhaust gases might have been led into a closed heater composed of large diameter coiled pipes around which water circulated, the heat of the exhaust within heating the water.

Provision was made for three cars, each with its own doors, and runway. In addition, there was a pit, but the maneuvering of the cars was all done outside on the large gravel court, directly in front of the building. This reduced the movement of the cars within the building to a straight in and out movement. The space is thus utilized to its fullest extent, all of the inside space around the cars being useful for working on them. To take any car to the pit, even if there was a car already over it was a simple operation consisting of but two motions. The car on the pit ran straight out, describing an S curve to the left side of the court, and stopping at the outer edge of the latter as far away from the house as the court extends. It was then in a position to back directly into the place vacated by the other car.

In bringing out the car to go to the pit, it described another S curve, this time to the right side of the court. Then, a simple straight backward motion brought it through the door and over the pit, as desired. This operation was equally simple whichever car was moved, and to whichever place inside of the garage it was intended to move it.

Another Set of Plans—To close out the concrete story, another set of plans will be given. These show the largest yet shown. In size, it is 30 feet long by 24 feet wide, sufficient to accommodate two cars easily, and if the doors are planned right, three. In fact, the actual floor space afforded by this design is but 15 per cent. less than shown for the three-car garage on the previous page. In height, a peaked roof, coupled with the large width and a normal slant, have resulted in a height of 18 feet 6 inches. With a mansard effect, this might have been reduced to 16 feet 6 inches, or by redesigning, with this object in view, to 14 feet 6 inches.

Both changes would, however, result in an increase in the cost of the roof trusses, these being four in number. Had the roof been planned of wood or other materials, this change would have turned out to be a money saver, but with the extra work of the structural roof trusses, the saving in material is more than offset and the result is increased expenditure.

To many, this, resulting in an improved appearance, would be well worth while, since a person constructing a two- or three-car garage, does not have to figure in the pennies. It will be noticed that the design calls for a structural framework, for which the natural covering would be some form of metal lath, covered with cement plaster. The exterior, however, might be given a smooth, a stucco, a pebbled, or other appearance as fancy dictated, the basic design being so as to allow any one of these, or combinations of them.

Provision is made for a small door and a window at one end, which may be varied for the other end to three windows, one in each bay. Or, the door-and-window effect may be duplicated. At the side, one large double door and two windows are shown, the other side being left to the builder's fancy. This would doubtless result in the most useful form, namely three large windows. The side shown, on the other hand, would be altered for two or three cars by the changing of one or both of the windows into additional means of ingress and egress for the cars. These would take the form of more double doors, duplicating the one shown.

Both the changes from windows to doors would reduce the expense of the steel work, as extra framing would be eliminated by the change. To replace doors by windows, on the other hand, would have the opposite effect, in that the framing would be increased, and with it, the cost.

Amount of Material Called For—In estimating the material necessary and the cost of the same, for this garage, the following result was arrived at:

Bill of Material and Estimate—Three-Car Garage

Roof, 1,150 sq. ft. of metal lath. 1,110 sq. ft. of 1½-in. concrete and plastering on inside. Waterproofing at 3 cts. per sq. ft.	$33.30
Walls, 1,220 sq. ft. metal lath...... 1,200 sq. ft. 2 in. plastering.	
Windows, complete in place.......	15.00
Doors, complete in place..........	29.00

By far the largest item has been left out, namely the metal lath and its covering. The cost of this might run up to ten times the other items, taken collectively, so that it is idle to try to estimate the cost from this scant data. As a rough guess, this garage should cost at least $1,500.

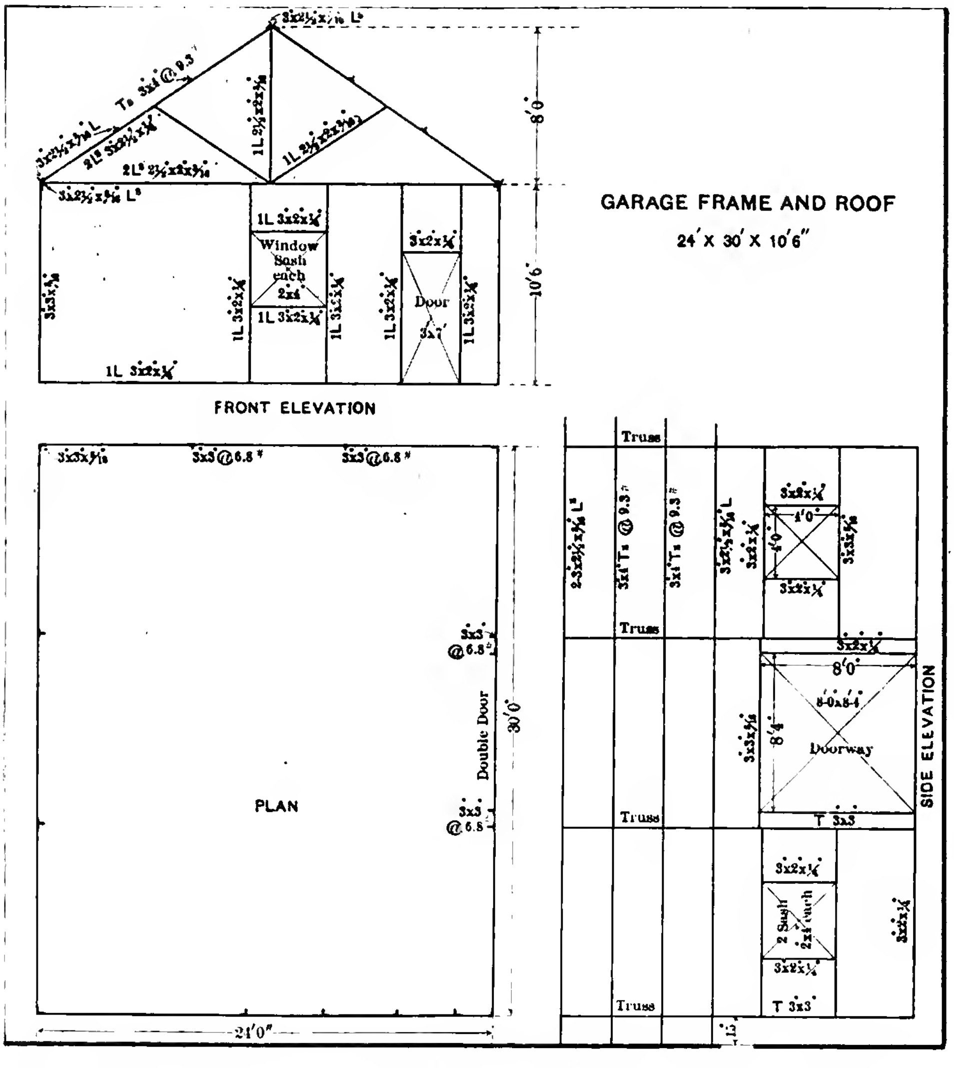
An estimate of the weight of this structure gives these quantities:

Frame and connections.....	1,370 pounds
Trusses, four at 500 each, with connections..........	2,000 pounds
Purlins, angles, tees and connections	2,130 pounds

Making the total weight without windows, doors, paint, blinds, floor, or interior equipment at least 5,500 pounds.

From this, the total weight on the foundations might run up to 8,000 pounds, or four tons, very easily, and in the case of a very thick, heavy floor, to 9,000 pounds or more.

One other noticeable fact of this design is worth attention. In the usual case, there is plenty of room for the garage, so that the matter of a proper approach, in connection with the doors need not be given a thought. There are cases, however, in which



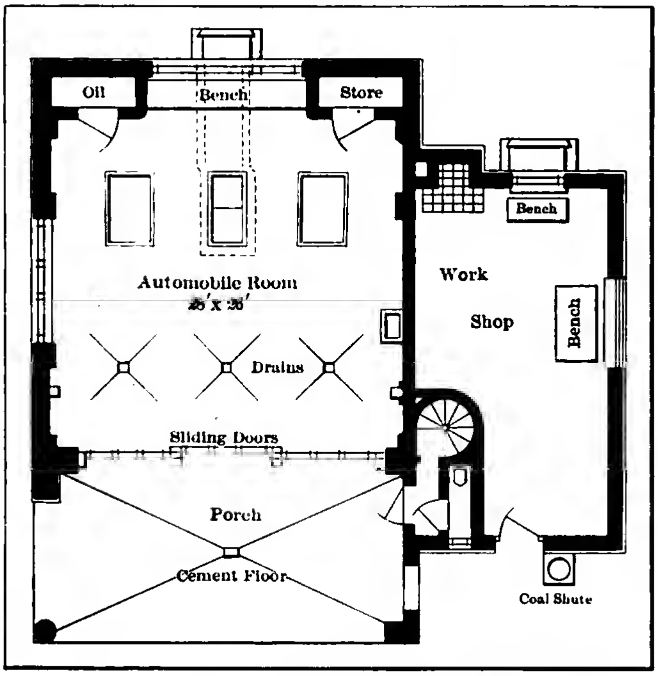
Framing Plans of Iron Work for Three-Car Concrete Garage, Thirty by Twenty-four this design might be favorably thought of, but under conditions that precluded the use of side doors. This has been provided for by leaving the left hand end panel blank, or plain. In a case where the side doors could not be utilized, this space would be large enough for any sized door, being 11 feet by 10 feet 6 inches. In the usual case, additional framing would be resorted to with the use of an 8 feet by 8 feet 6 inches double door.

Illinois Man's Design Presents Novelties—Elsewhere on this page is shown a garage (concrete) built by an Illinois man, which shows a number of novel and interesting features. The drawing shows only the ground floor plan, the second story being devoted to living rooms for the chauffeur. Since the arrangement of the latter has very little connection with the garage story, no attempt will be made to illustrate or describe it, other than to call attention to the winding stairway, reached from both inside and outside by separate doors. This is fully as effective as any other form, and economizes on space.

Three cars are provided for, although the owner has but two. The provision, in marked contrast to the usual case, is in triplicate, three pits and three washstands being provided, as well as three doors. The front end of the house includes a porch with cement floor and housed over by the living rooms above. This would, without doubt, be used for most of the washing done in fine weather, in preference to the washstands within. In fact, it would appear as if the designer, a well-known Chicago architect, had this idea in mind.

Most notable in the whole design is the large and very roomy workshop provided alongside of the motor room, yet entirely separated from the latter by a thick solid wall. Without a doubt, this would reduce the fire hazard very materially were the gasoline kept in the work room. The floor plan, however, does not indicate this, and the oil being in the automobile room, one is forced to the conclusion that the fuel was kept there as well. In that contingency, not only is the fire hazard not reduced, but on the other hand, all parts or units to be worked upon would of a necessity have to be taken out of the car, carried outside through the big sliding doors, and then back into the work room through the front door. The same process would have to be gone through after the repair had been effected. It sounds like a small thing, but this would mean lots of extra work, and looks like a real flaw in the design.

Among the good features may be noted the location of all work benches—there are three shown—in front of windows. The only work bench in the automobile room is placed at the back in front of the large and wide window there, while the two benches in the shop are placed directly in front of the only windows in that room. This will give lots of light for work that is to be done. Light is very important, and although the doors were intended to have windows set into them, it must be said that the provision for light in this case has been subordinated to architectural effect. Thus, the main room should have another window the size of the present one, the two being set equal distances from the front and rear. More than this, there should be another large window in the side of the work room, the present one being moved back so as to make room for it.



Lincoln, Illinois, Concrete Garage of Original Features

Two-Story Garage of Terra Cotta Hollow Tile Construction

Hollow Tile Concrete-Covered Garage—This fault, lack of light, is not found in the other garage illustrated on this and the next page. Not only are there many windows on each side, two being placed at each end of the room, but the ends are well lighted. The latter is effected by means of windows in the doors, and in addition a good-sized window on each side of the big doors. That this really results in a well-lighted interior may be seen in the interior picture, taken by natural light.

This building is constructed of terra cotta hollow tile, covered with cement, the latter giving it all of the appearances of a concrete house, while retaining the good features due to the hollow tile. One of the first questions raised in connection with any such form of construction is that of the cost. In answer to the unspoken question of costs, the following table shows an estimate of the costs of different systems of building, based upon an average dwelling located in the vicinity of New York City:

(a) $10,000 Frame.
(b) $11,000 Brick outside walls, wooden inside.
(c) $10,250 Stucco on expanded metal, wooden inside.
(d) $10,500 Hollow terra cotta blocks stuccoed, wooden inside.
(e) $12,000 Hollow blocks stuccoed—fireproof throughout except roof.
(f) $14,000 Hollow terra cotta block walls faced with brick, fireproof floors and roof.
(g) $15,000 Brick walls—fireproof floors and roof.

The above figures are based on an average taken from two architects and two builders, who have had experience with the methods of construction designated. Reducing these figures to small units, taking the frame dwelling as unity, we have: Frame, 1; brick (b), 1.1; stucco (c), 1.025; terra cotta stuccoed (d), 1.05; hollow blocks stuccoed (e), 1.2; hollow terra cotta, brick-faced (f), 1.4; and brick walls, fireproof construction (g), 1.5.

Applying these to an average garage ample for one car, and well designed, the resulting figures would be: (a) Frame, $1,000; (b) brick outside walls, wooden inside, $1,100; (c) stucco on expanded metal, wooden inside, $1,025; (d) hollow terra cotta tile blocks stuccoed, wooden inside, $1,050; (e) hollow blocks stuccoed, fireproof throughout except roof, $1,200; (f) hollow terra cotta block walls faced with brick, fireproof walls and roof, $1,400; (g) brick walls, fireproof floors and roof, $1,500.

This particular garage is built for one car, and as such the floor space allowed is unusually large. This being the case, the chauffeur's quarters above, occupying the whole second floor, are

Interior of Garage Part of Hollow Tile Building

also very commodious. This is the Morris garage at Westchester, N. Y., and is built of hollow terra cotta tile, covered with cement. The construction, in fact the tile themselves, may be seen in the picture of the inside shown elsewhere on this page.

These are set up on edge, so that the hollow or hole through the base layer carries clear up to the top. The ceiling, in this case also the floor for the second story, is made up in the same way, except that the tile are laid flat so that the interior holes progress across the building. The floor tile are laid between reinforced concrete beams, which form the supports. If desired, the supports could have been structural steel, either I-beams or channels, or wooden beams might even have been used. The latter would have the advantage of giving a good foundation to which to attach floors or ceilings of wood, but this would be completely overbalanced by the fact that their use would detract from the fireproof qualities of the structure.

In the foreground may be noticed the drain for the washstand, the interior of the garage at the time this picture was taken being bare just as the builder left it, and before it had been occupied by either the chauffeur or the car.

Terra Cotta Garage in Process of Construction—The two illustrations below show a garage-stable as completed and when but partly completed, a before and after effect. In the left hand picture the building is about half finished. The tile may be seen very plainly, the lines of demarkation between each tile and its neighbor being distinct.

In the second picture is shown the garage as finished, the tiles for the roof being in place, the walls covered with the cement plaster, and the dormer windows being coated as well. This picture is not taken from the same viewpoint as the first one, as the first shows the back, while the last one shows the front of the building with the entrance at the left.

It is a wide, spacious entrance, flanked by a pair of square posts of good height. The doors and windows used carry out the scheme of the rest of the building very effectively. This structure is located at Monmouth Beach, N. J.

A record was made in its construction, ground being broken on May 9, and the building being completed on July 3. This made the elapsed time but 55 days. The tile used varied somewhat. Those for the first story, that is, up to the eaves, were 8 inches thick. All tile used above that were smaller, of but 6-inch thickness. Despite the very ornamental character of this building, and the great haste in which it was erected, the cost was very low. This amounted to but 22 1-2 cents per cubic foot of contents, that is the whole cost, divided by the number of cubic feet in the walls, etc., amounted to this figure. The roof tile are a bright red in color, and in form are the S tile. That is, the section through the tile forms an S. In assembling or laying, half of each tile overlaps the one next to it, the water and weatherproof qualities being obtained by this overlap.

Strength of Hollow Tile for Floors—The idea that tile has no horizontal strength is somewhat prevalent. This idea is erroneous, as will be shown. Thus, a floor system composed of hollow tile set horizontally, with a 4-inch beam of reinforced concrete between each pair of tiles, the concrete carrying varying sizes of rods and of a composition of 1 part Portland cement to 3 parts sand and 5 parts gravel, has the following strength:

LOAD TABLE OF HOLLOW TERRA COTTA TILE FLOORS

Safe Live Load in Pounds per Square Foot—Factor of Safety=4

Span in feet	12-in. Tile, 1-in. Dia. Rod; Weight per sq. ft. 68 lbs.	10-in. Tile 7/8-in. Dia. Rod; Weight per sq. ft. 58 lbs.	9-in. Tile, 7/8-in. Dia. Rod; Weight per sq. ft. 57 lbs.	8-in. Tile, 7/8-in. Dia. Rod; Weight per sq. ft. 48 lbs.	7-in. Tile, 3/4-in. Dia. Rod; Weight per sq. ft. 43 lbs.	6-in. Tile, 3/4-in. Dia. Rod; Weight per sq. ft. 38 lbs.	5-in. Tile, 3/4-in. Dia. Rod; Weight per sq. ft. 30 lbs.	4-in. Tile, 5/8-in. Dia. Rod; Weight per sq. ft. 26 lbs.
5	2512	1942	1608	1377	934	692	477	294
6	1722	1327	1100	942	636	470	220	196
7	1247	962	796	680	456	334	230	127
8	941	725	596	509	338	248	168	99
9	729	559	461	392	258	188	127	73
10	577	442	363	308	202	145	97	54
11	466	355	291	227	158	113	75	40
12	379	289	236	199	126	89	58	30
13	312	238	192	163	101	70	45	21
14	261	197	160	134	80	56	35	14
15	218	164	132	110	65	43	26	9
16	184	137	110	91	48	33	19	5
17	155	115	92	75	41	25	14	...
18	131	96	76	62	31	18	9	...
19	111	81	62	51	22	11	...	...
20	93	67	52	41	17	8	...	...

For a floor of cement, 1 1-4 inch thick, laid on top of this as a finish, the size of rods is increased by 25 per cent., all other figures being the same. The strength of the floor system is then increased by about 75 per cent. above the figures given in the table above, and from that figure on upward, to as high as 160 per cent. in some cases, the exact figures not being of sufficient interest to warrant repeating the table here.

(To be continued.)

Hollow Tile Garage in Process of Construction

Same Garage as It Appeared When Completed

UTILITY AND IMPORTANCE OF PROPER ENGINE TESTING

BUFFALO, N. Y., Nov. 29—The E. R. Thomas Motor Company has inaugurated a system of block testing that ranks with the best in the country. In the past, many factories have regarded the block-testing department as unimportant, and except the function of running in the engine, so that it could be turned over or started easily in the road test. This being the case, the department set aside in most factories is a dark room, poorly kept and lacking in attention in every way; not only is it disgusting to the visitors to go into such a department, but to the workmen as well, with the result that the general contrast between this department and the other departments makes the men feel that they are of less importance to the concern.

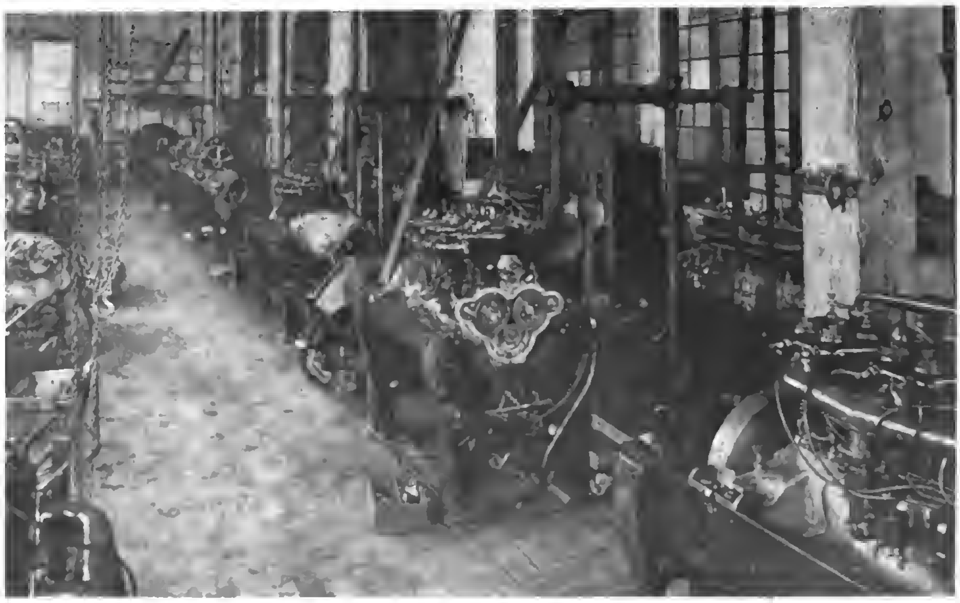
Thomas Engine Testing Department from East, Showing "Little Six" in the Foreground

It was early realized by the Thomas company that the dormant opportunities of well-kept and carefully managed departments invariably yield in return a more finished output. Their designers visited the different factories in the United States for the purpose of inspecting and acquiring all the good points and means of eliminating their bad points. The result is that the motor-testing building is modern in every particular. Visitors are impressed upon entering this department with the large amount of light, the general cleanliness of the floor, and the alert activity of the men, so that it is possible to regard this department as a laboratory where the design of the engineering department and the practice of the shop come together for a test of practical use. For instance we might regard the twenty units or blocks as twenty individual power plants, each of which is to be brought to its highest working efficiency before it is turned over to users; each one is treated in a similar way, so that any change in the general performance is easily noted by its contrast. This is of the greatest benefit, not only to the engineering department, but to the customer, for it implies a concentrated attention to every detail, no matter how small, is seldom found.

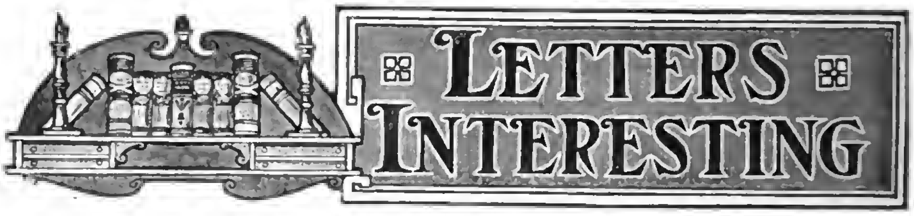
Before the engine is allowed to go to the brake test it is brought into the department and thoroughly inspected, then it is "run in" for a period of five hours to determine if the assembling has been correct, and also to limber the engine preparatory to runnning under its own power. The engine is then run under for a period of 50 hours, after which it is "torn down."

Each motor is mounted on a heavy framework, cast iron and steel, in such a maner that every part is accessible and easily observed. The water and gas connections are attached in exactly the same manner as they are on the cars, so that as far as possible the performance of this same motor can be interpreted upon the road before it is assembled in the chassis. The water, for instance, as it leaves the motor is at all times observed; in this way it can be told whether a motor is overheating or requiring an excessive amount of water to keep it cool. Directly connected to each motor, and in the same frame, is a hydraulic testing dynamometer or brake so regulated that any desired load can be "thrown upon" the motor. Starting at a low speed and going up to 1,500 revolutions per minute, the horsepower is noted, and the "characteristic" curve plotted from this data. These curves are plotted upon regular cross-section paper, with the average performance, so if the motor falls below the average performance, it is instantly detected, and either is tuned up during the test or entirely gone over at a later time.

The character of the assembly work and all of the parts are inspected and defective ones are immediately replaced. After the engine has been assembled it is run-in for a period of five hours and then put on its severe brake test. It is then rigidly inspected by a man not connected with the department—one that has an unbiased opinion as to the finished product. No engine can go out of the department until it develops the horsepower specified at all speeds by the engineering department. The cards that contain this data are at all times kept on record and open for inspection by all interested customers of the concern.



Testing Room from West, Displaying Large Number of "Fours" Under Test at One Time



CAR HARD TO CRANK

Editor THE AUTOMOBILE:

[2,101]—I have a 45-horsepower Lozier car which I cannot crank because of a lack of strength and which almost kills my man if he has to turn it over more than once or twice. I have written to the Lozier people about it, but they tell me that they can do nothing to help me out. Other cars (Alco and Packard) have devices that overcome this kind of trouble, and I would like to find out if any users of the Lozier cars have succeeded in getting anything that makes the car a possible car to run. Can you suggest any way for me to obtain this information?

Paterson, N. J. C. S. J.

As we have never heard of this trouble among Lozier owners or drivers previously, we cannot advise you what others have done.

Speaking generally, the reason why your car is hard to crank is because it has high compression and tight piston rings which retain the compression. Both of these are inseparable from high power and high speed. On the other hand, both of these should make starting on the spark an almost invariable performance.

In case you have not been able to start on the spark and are still unable to crank the engine readily, the thing to do is to obtain a device which will relieve the compression in part and which may be worked at starting time and then moved back so that the full compression is obtained for running. This may be effected as follows:

This engine, like every other one, must have compression relief cocks on top of the cylinders. Take out all of these, and with hack-saw or other tool cut a 1/8-in. slot about 3/8 in. deep into the handle of each one. Then drill through the slotted parts—that is, at right angles to the slot and about half way down into it—a 1-8-in. hole. Screw all cocks back into place, turning them until all slots lay parallel and in the fore and aft direction—that is, parallel to the crankshaft.

Either obtain or make a long, flat bar of steel about 1/8 in. or slightly less in thickness by 1/2 in. wide. This set into place in the slots in the cock handles, and after marking the position of the holes therein drill the four necessary holes. When the bar is put back into place, put in four 1/8-in. pins to hold it to the cock handles. This bar may be made long enough to reach through the radiator, the front end being turned down to a small enough size to pass through one of the radiator tubes in a lathe. When this has been done the protruding front end may be bent over to form a handle.

Now, what you have just done is to connect up all of the cylinder relief cocks in such a manner as to allow of relieving the compression in all four cylinders, without lifting the bonnet. To start the engine, the bar will be pulled forward slightly, thus relieving the compression in all cylinders, the amount of the motion of the bar being judged by experience, since too much movement will result in lowering the compression to such an extent that the engine will not start. Your man will soon learn how to manipulate this, notches in the bar being provided so as to insure the same amount of movement each time, so that, when the best starting position has been found, it may be kept for future use.

If desirable, a fine job may be made by adding a fancy handle at the front with a quadrant to work over, etc. This, however, would work no better than the one described.

The whole thing should be made and applied to the car by your man at an expense not to exceed $1.50.

WHO'S THAT A'KNOCKING?

Editor THE AUTOMOBILE:

[2,102]—I have a 1910 Model T Ford, on which the valves are clean, the pistons have no carbon, the engine runs well and has plenty of power, but it has a knock that is very plain.

If I hold down the second or third vibrator of the coil the knock disappears. The engine has been taken down and crank bearings tightened. Adjusting the needle valve of the carbureter makes no difference. If you can explain this difficulty it will help me very much.

A SUBSCRIBER.

Massena, Iowa.

Your description of the trouble seems to suggest its own remedy. If holding down vibrators two and three causes the knock to disappear, is it not a truism that the trouble is confined to those two? Similarly, if changes in the fuel system have no influence on the knocking, while simple changes in the ignition system remedy the objectionable feature at once, is it not plain that the trouble is not in the fuel, but in the ignition system?

With this to start with—trouble confined to ignition of second and third cylinders—it ought not to take you very long to find it and fix the trouble.

Now, pounding or knocking may be caused by uncertain ignition. This in turn may be a weak coil, a loose connection, or a short circuit in the coil due to oil or water. The first may be proven by borrowing a coil for a long enough time to try if the knock will cease. The second may be found by inspection, and seems unlikely. The third and last can be remedied by taking out the sections which give trouble (two and three), drying them in an oven or over a radiator, care being used to have a very slow, gradual heating process, which will not harm the delicate coil. As far as the weakened action of the coil, the first named trouble, is concerned, you might try new springs for the tremblers on cylinders two and three, the offending ones. The simple expedient suggested of borrowing a friend's coil long enough to test it will show you quickly if the coil is at fault. If you find this to be the case, and cannot fix it, a new coil will soon put you right.

GENERATOR COOLING

Editor THE AUTOMOBILE:

[2,103]—Will you please answer the following questions through your valuable department, "Letters Interesting, Answered and Discussed"?

1. Will wood alcohol mixed with water be safe to use in a carbide light plant, or is there any other cheap mixture which could be used in the Winter?

2. Would filling the water jacket of the carbide chamber with wood alcohol be of any benefit in cold, freezing weather?

I would gladly receive any other suggestions relative to the prevention of freezing in this system of lighting.

Bagley, Iowa. R. J. NAYLOR.

Both systems of preventing the freezing up of the carbide generator could be used to good effect. The method of putting the anti-freeze in the water jacket seems more reasonable than the other way, although as described by an old subscriber elsewhere in this issue (letter 2,108), this method is very effective, and, if anything, seems to improve the light obtained rather than the contrary, as one would think.

If you wanted to use the anti-freeze in the water jackets instead of inside of the generator, a cheaper mixture than alcohol could be made, using common salt, with which a temperature of minus 5 deg. may be maintained without the mixture sensibly thickening. If your part of the country is not subject to long spells of cold weather, in which the temperature goes below minus 10 deg. Fahr., this salt mixture would certainly be as useful as any other, and infinitely cheaper.

STORAGE BATTERY FREEZING

Editor THE AUTOMOBILE:

[2,104]—Will you please advise me through the columns of "Letters Interesting, Answered and Discussed," at what temperature the electrolyte of a storage battery will freeze, also the time required?

CECIL E. PATTERSON.

St. Marys, Ont.

This is a trouble of which we have never heard, from which we are forced to conclude that at any ordinary temperature the liquid of a storage cell is practically unfreezable. More than this, your question is too indefinite. Electrolytes are of differing densities, one at charging, another at discharge, and still others without number in between. At every different density, the freezing temperature (if there is one) and the time required would be different. So, even if we were able to answer your question by means of exact figures, a very long table would be necessary in order to give all of the possible densities to be met with in storage battery work. The average temperature of charging runs from 100 deg. F. on up, according to the speed of charging and the condition of the battery and acid at that time.

Answered and Discussed

BLOWING HIS OWN HORN

Editor THE AUTOMOBILE:

[2,105]—I have a Ford 15-horsepower runabout and wish to blow the horn on the same by compressed air. Could I have a tank, about 12 in. by 6 in., placed somewhere on the machine, with a pipe leading from, say, the rear cylinder to the tank. I would put a check valve in the pipe and tap into the exhaust valve cap for my supply. When the engine is running gas would be forced through the pipe and into the tank. When the pressure there was equal to the pressure in the cylinder at the time of explosion no action would take place. The gas could not leave the tank on account of the check valve.

Could I use this same tank of gas to inflate tires? Please answer through "Letters Interesting, Answered and Discussed."

Warren, Mass. LOWELL S. ELLIS.

The answer to your questions is yes to both. The tank could be rigged up as you suggest, but it would be advisable to use a much larger tank, say, about 12 in. by 24 in. This gas could be used for pumping the tires as well as for blowing the horn. But the action of exhaust gases or even highly compressed unburned gases from the cylinder previous to explosion upon the rubber composing the tires has not yet been fully explained. As you will find by referring to the files of THE AUTOMOBILE for last Spring, when this subject was discussed, this is open to argument. Some claimed that the cool, moist gases previous to explosion were beneficial to the rubber, while others said that it was impossible to do this without getting some gasoline either as a liquid or as a vapor into the gases. Gasoline is well known as a solvent for rubber.

You would find the attachment of this tank well worth your while, as the compressed gases could be used for many purposes, even to the starting of the engine. The latter, however, would call for a timing apparatus which would have to be driven off of the engine, and so might result in more complication than you would care for, having a small and easily started engine.

TWO-BEARING ALIGNMENT

Editor THE AUTOMOBILE:

[2,106]—On a number of cars brought out this past season the motor is fitted with a two-bearing crankshaft, fitted with plain bearings. Is it not a fact that a shaft having but two bearings, and plain bearings at that, will, sooner or later, be thrown out of alignment? GEORGE CHRISTMAN, JR.

Spring Lake, Mich.

Nearly all of the very small engines cast in a block—that is, the four cylinders in one casting—have the two-bearing shaft. However, most of them use ball-bearings. The argument in favor of this practice is that the elimination of the middle bearing shortens the length or distance between the end bearings by a very large amount, varying upward from 2 1/2 in. This shortened shaft is then stiffer because of the decreased length between supports, while the majority of builders go farther and make the two-bearing shaft of larger diameter throughout. This also adds to the stiffnesss and reduces the liability to bending or to lack of alignment.

Now, with ball-bearings the two end supports give the shaft but point contact—that is, it is supported upon two points, one at each end. In case anything should tend to throw the shaft out, or in case of excessive strains tending to bend the shaft, the point support would allow the shaft to vary slightly, which would not be the case with plain bearings. The latter would grip the shaft for a distance equal to their length, preventing any variation at that point. Strains set up in the shaft then, in the case of the plain bearings, would result in actual shearing off, or, in a milder case, in the bending of the shaft.

This being the case, then, the only resort for the makers using the plain bearings is the enlargement of the diameter to such a size that bending is impossible. In case this is not done, or if the shaft is of small diameter, the buyer should be careful. There is a certain relation between the diameter of the cylinders, or power, if you prefer, and the section of the crankshaft, the strength of the material being known. Knowing this relation for a successful and perfectly safe motor with three or more bearings, you should add to the factor of safety a certain amount for the two-bearing shaft. This, then, would give a size for the two-bearing shaft which, in the absence of definite knowledge, might be considered safe. In that case it would not be advisable to buy an engine with a shaft smaller than the one decided upon as safe.

In weighing the merits and demerits of the two-bearing crankshaft, you should take into account the fact that length means weight, so that every inch saved—and this construction saves upward of five—means many pounds weight eliminated. This saving in weight is taken off the tires. As a result, the tire expense is lessened. Since this is by far the largest factor in the cost of upkeep, the latter is materially reduced. More than this, less weight with the same power spells either greater speed or improved gasoline economy. In this latter, you must take your choice, for you can not have both.

This weight saving, for instance, carries farther than one would think. Thus, not only does the cylinder casting itself weigh less, but also the exhaust pipe, inlet pipe, both inlet and outlet water pipe, crankcase, and many others.

PNEUMATICS FOR SOLIDS

Editor THE AUTOMOBILE:

[2,107]—The solid rubber-tired wheels of my 16-horsepower automobile are 34 inches in diameter. The felloes are 1 1-2 by 1 1-2 inches (not counting iron and rubber). Hubs are artillery, 16 spokes. Would it be possible to remodel them so as to use a 36 by 3 pneumatic tire? Would this affect the running? The machine is friction-drive, side chains, sprockets 8 and 52 teeth, and capable of 30 miles an hour.

Ruston, La. B. F. DUDLEY.

The change should considerably improve the riding qualities of your car, as it is bad designing to use solid tires of the ordinary type on wheels as small as 34 inches. Further, we believe the change would be thoroughly practical. A 36 by 3 pneumatic goes on a fellce 29 11-16 inches in diameter, not counting the rim. You do not say how thick your present solid tires are, nor how large is the diameter of the felloe, but it should be approximately that figure. A 36 by 3 1-2 pneumatic requires a 28 11-16-inch felloe. We would recommend the 3 1-2- inch size if your wheels will permit the use of it, unless the car is very light.

The difference in gearing due to the use of 36-inch wheels instead of 34-inch would be very slight; it would be higher in the ratio of 34 to 36. That is, with your car geared at present for 30 miles an hour, the change would gear it for slightly less than 32 miles. If you have hills or soft roads in your vicinity which would make this gearing too high, you might change the rear sprockets to, say, 55 teeth.

Larger sizes than 36 inch would be special and require a special wheel, in all probability. The last-named change, from a 52 to a 55-tooth rear sprocket, keeps the speed the same as at present with 36-inch tires.

ANTI-FREEZE CAN BE USED

Editor THE AUTOMOBILE:

[2,108]—I note that in your answer to Letter No. 2,083 asking for an anti-freeze solution for generators, you say there is nothing which can be used for the upper tank. The writer has used as high as 40 per cent. wood alcohol solution without apparent effect on his lights. If anything, they seemed somewhat improved. Enough water will flow to make gas, and the alcohol is vaporized by the heat, and burns.

With regard to anti-freeze for the radiator, the writer used a 50 per cent. glycerine solution ten years ago on a one-lung Winton, and has used it ever since on a dozen cars, with thermo-syphon circulation and all kinds of pumps. The strength of the solution has been gradually reduced, on account of expense, to 25 per cent., which in this climate is enough. A little slush will form at temperatures near zero, but it will go through the pump readily, and never cause any trouble. If it harms rubber, as it is reputed to do, it is not noticeable in a season's use.

One year a ready-made and widely advertised solution was used which ate out all the aluminum it touched (name forgotten). The alcohol and alcohol glycerine solutions were tried, but were found to boil too easily, and to seek out the smallest leak, while the glycerine forms a jelly when exposed to the air and will actually stop small leaks.

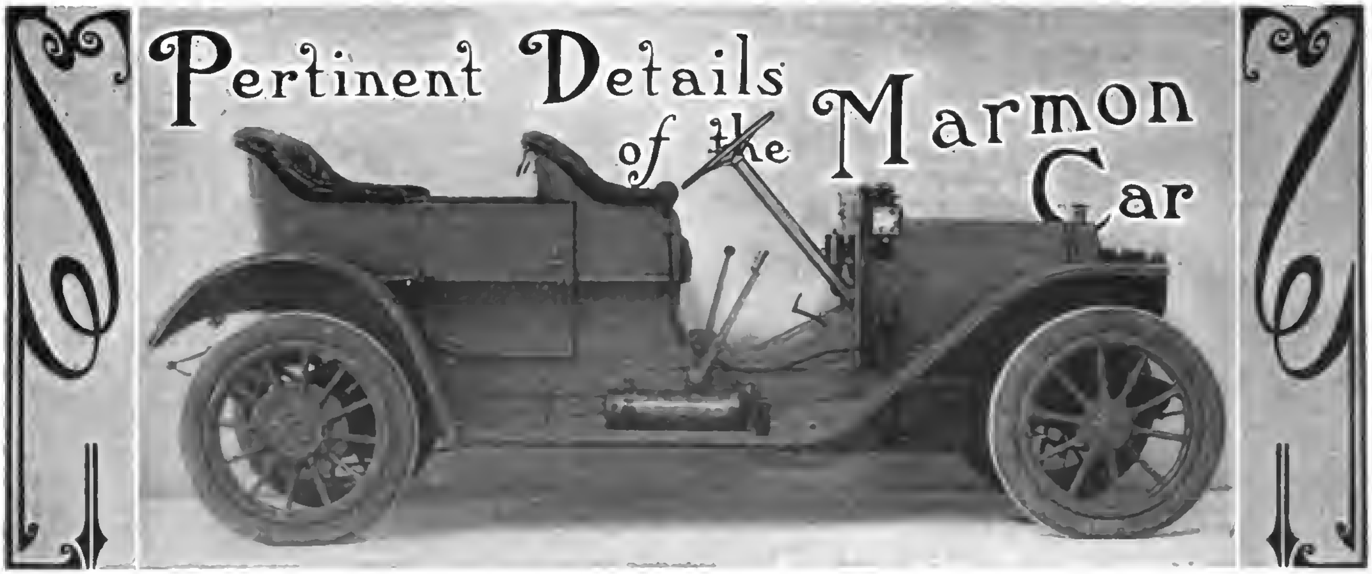
The writer's experience with glycerine has been so wide and so satisfactory that he would not hesitate to say that it is absolutely satisfacory for any case.

For the benefit of our friend who wants names, it has been used by the writer and his friends on a 1900 Winton, 1903 Olds, 1904 Cadillac, 1906 and 1909 Gaeth, 1908 Garford "30." 1908 Ford, and 1907 Packard.

AN OLD TIMER.

Cleveland.

Pertinent Details of the Marmon Car



Marmon "Thirty-Two" Suburban Touring Car, with New Four-Passenger, Short-Coupled Body

FROM the year 1851 down to the present time the Nordyke & Marmon Company, at Indianapolis, Ind., has been practising up for what would now seem to be an absolutely standard effort, as represented in the Model Thirty-Two car for 1910, and while it is not the purpose here to claim that the automobile has been on the tapis all these years, even so, the plant has been devoted to a refined class of work, and "micrometer rule" has dominated the situation from the very inception.

When the company added an automobile department to its large plant it went into the matter rather cautiously, and by dint of a good deal of preliminary engineering work evaded many of the pitfalls of other pioneers. The result is that the present car, while it is up to date in every particular, is not so different from the last year's model as might have been supposed, which is another way of indicating that a standard product changes with the standard, and while there are many who fail to appreciate that standards do change, the fact remains.

Model Thirty-Two, which is the Marmon chassis for 1910, has a little longer wheelbase than last year's car, and the motor is suspended by a separable (flanged and bolted on) arm at the end of the crankcase, between it and the flywheel. The arm, as secured into place, takes the flywheel gyrations more perfectly, and the facility of a three-point suspension adds to the value of this method. As a further advance with the standard, the steering linkages at the front axle are so nested that they are out of harm's way. Some advances in material and methods of treatment have also been made.

The product of this well-known plant for many years was mill machinery, and long before the automobile was a noticeable factor in industrial life the company used micrometers instead of carpenters' rules, jigs instead of approximations, and system became a habit.

Some Technical Features Taken at Random—The scheme of design is outlined in Figs. 1 and 2 of the chassis, in side elevation and plan, respectively. While the specifications cover all that the chassis drawings depict, even so there are certain accentuated points in design that greet the eye and demand further recognition. The drop frame F, of the channel section, is 4 1-2 inches deep, gives good clearance at the axles, especially at the rear, where the motion is the most pronounced, it being fully 4 inches at C, Fig. 1, between the underside of the frame and the top of the bumper; the give of the bumper B adds to the clearance. The rear spring suspension, S, is full elliptic, 42 x 2 inches, which is indicative of easy riding qualities, and the material used is claimed to be superior for the purpose.

The four-cylinder, water-cooled motor M is provided with a high raiser, R1 and R2, with a flexible connection, H1, between the two pairs of cylinders and H2 from the front pair of cylin-

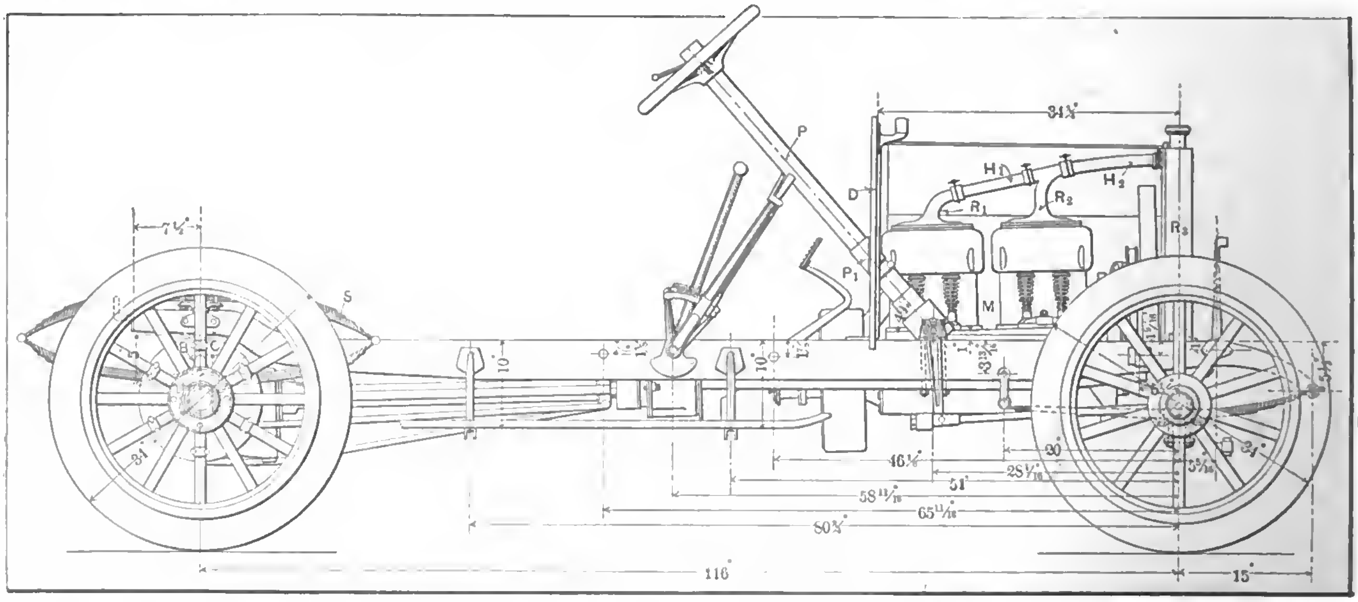


Fig. 1—Side elevation of chassis, showing position of motor, radiator on center line of front axle and drop frame suspended on full elliptic rear, and semi-elliptic front springs

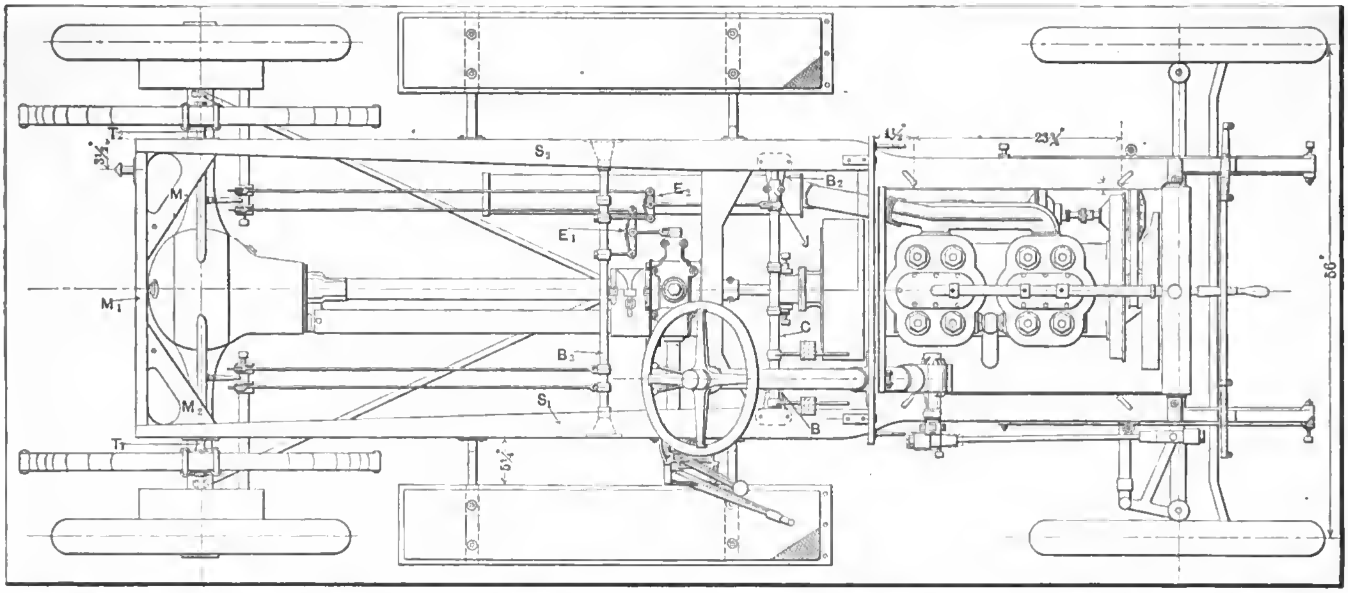

Fig. 2—Plan of chassis, offering evidence of strength and stability, with widened flanges of side members at point of narrowing

ders to the radiator, R3. The radiator is in a line above the front axle, and the over all distance from the center line of the front wheel to the front edge of the mahogany dash D is 34 3-4 inches, which length is enough to balance the general appearance of the car. The steering column, P, is securely braced at the point where it passes through the dash D, and held in secure relation by means of a plate P1.

The plan of the chassis presents evidences of strength, as, for illustration, the flanges of the side members S1 and S2 are widened as the dash is approached, and where the frames are narrowed in, supports are close at hand to tie up the work. The clutch shaft C passes clear across, and the brackets B1 and B2 are securely riveted to the frame, while the journals, one of which shows as J, are long and well fitted. What is true of the clutch shaft C is also to be said for the brake shaft B3, and in the same figure the equalizers for the brakes, at E1 and E2, will be easier to discern than in any other view available. The rear cross member, M1, is provided with unusually liberal corner braces, M2 and M3, and the rear spring trunions, T1 and T2, are provided with wide flanges and securely riveted to side-frames

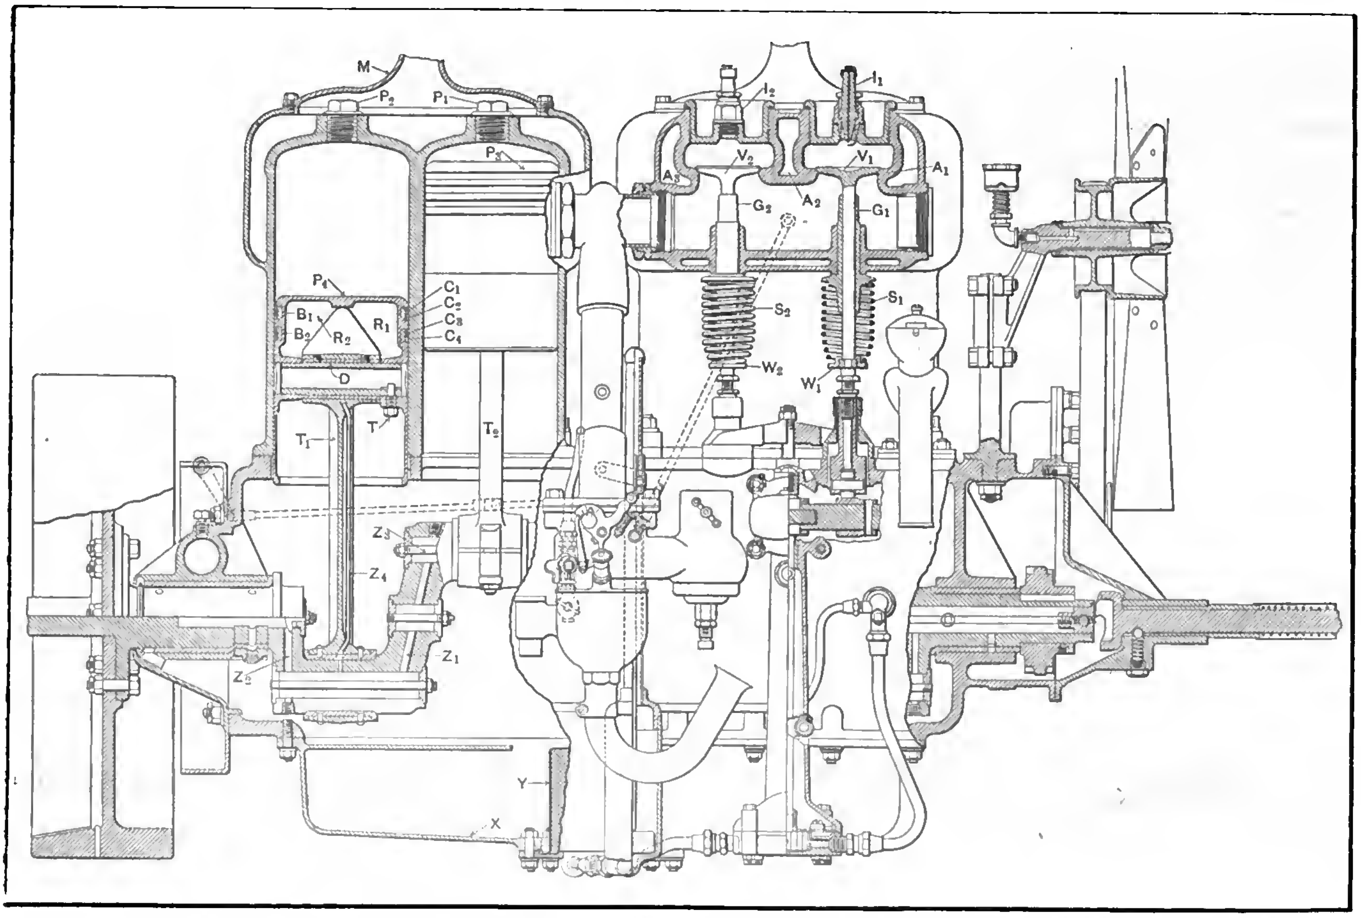

Fig. 3—Right side of the motor, in part section, disclosing light reciprocating parts, a competent oiling system, and nice details

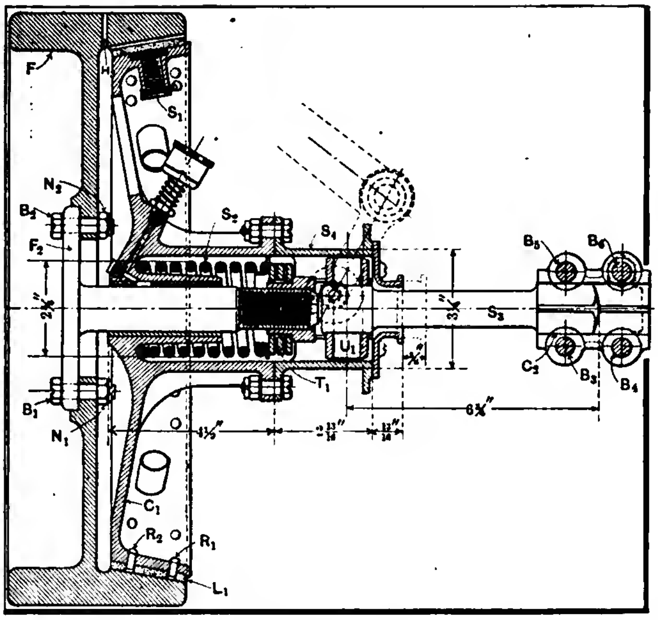

Fig. 4—Section of flywheel and cone clutch, presenting such details as mushrooms with springs behind them to press leather facing out, etc.

Refinements in Design of the Motor—Referring to Fig. 3, of the motor, looking at the intake side, which is the right-hand side when the motor is in place in the chassis, the front pair of cylinders is shown in part section cutting through the intake valves V1 and V2. The valves run in sized guides, G1, G2, etc., and the valve springs S1, S2, etc., press against a flange turned on the guides G1, G2, etc., while the other ends of the springs rest on a concentric support, washer-like, W1, W2, etc.

The spark plugs, 11, 12, etc.. of which there are four on the intake side, are directly over the valves, and sooting or heating is eliminated. The water jacket extends all around the valve seats, as shown at A1, A2 and A3, for the first pair of cylinders, which plan is, of course, duplicated in the second pair of cylinders. Referring to the second pair of cylinders in the same figure, the plug in the head P1, P2, etc., is threaded in, passes through the inner wall only, and is submerged in water. The water jacketing is augmented by the bell-like shape of the water piping makeup, M, which is the same for each pair of cylinders, and the volume of water thus stored above the hottest part of the cylinders is insurance against cooling trouble. More than that, it aids very materially in the matter of efficient lubrication.

The pistons P, P1, etc., have flat heads, are strongly supported by ribs R1, R2, etc., and the packing is done, to maintain compression by means of compound rings, B1 and B2, in grooves for each piston, which rings support auxiliary rings C1, C2, C3 and C4 on each piston. The method of packing is one that has long been favorably considered in steam and other work, and the continued tightness in service is its best recommendation.

The piston pin D in each cylinder is hollow, of alloy steel, hardened and ground, and is prevented from floating by a cap screw, T, threaded into the boss and turned to fit in a hole in the piston pin. The connecting rods J1, J2, etc., are of the I-section, drop-forged from suitable grades of steel, and a bushing of bronze assures a good bearing at the piston pin in each case, while proper journal members, split and securely bolted, take care of the crankshaft crank bearings.

The reciprocating mass is reduced to a minimum, due to light pistons, connecting rods and a sufficient stroke to reduce the angularity to a safe point. Lubrication, which is positive and worked out to a nicety, does what is left by way of accounting for the fine performance. This lubrication, as the design reproduction indicates, is rendered positive by means of oilways reaching up from the oil in the "sump" X. After the oil is strained through the strainer Y it is pumped into the oiling system, and as an indication of the means afforded, attention is called to the oilways in the crankshaft Z1, Z2 and Z3, also in the connecting rod Z4, leading up to the piston pin.

Before departing from the discussion of the motor as suggested by Fig. 3, a glance at the fan detail, at the front, will disclose a point or two: The fan is large, is driven by a wide, flat belt, and the bearings are lubricated by a greasecup pressing hard lubricant in through the passageway Z5. The fan support is strong and is to the crankcase. There are additional details, to be sure, but enough has been said to enable the reader to take up the burden.

Simplicity Resides in the Clutching Mechanism—Fig. 4 refers to the flywheel F1, made of selected gray iron, cast in the Marmon foundry, at the plant where the cars are made, and instead of keying on, the flywheel is flanged to the crankshaft at F2, and is held in place by means of through bolts B1, B2, etc., with nuts castellated and locked, N1, N2, etc., by cotter pins. Any oil that accumulates within the flywheel is driven out by centrifugal force through holes around the periphery, one of which is shown at H1. This is a very practical preventive against that bogy of the novice, clutch slipping.

The cone clutch C1 has a dished spider, as shown in section, is made of aluminum, and because of its shape, all internal strains are removed and safety is assured. The leather face L1 is of a selected variety of clutch-leather, and rivets R1, R2, etc., hold the leather to the cone-face. Leather, when used in cone clutch work, if it is not pressed out by means of springs, is likely to give trouble, and the practice in this case is to cause the leather to press out by placing coil springs S1 behind mushroom-shaped members M1 around the periphery.

The clutch is pressed into engagement by the concentric coil spring S2, and the reaction is taken by a ball thrust bearing, T1. The shell S4 is flanged to the extension of the cone-spider just over the thrust bearing, and a universal member, U1, takes the power on its way to the live rear axle, passing it through the stubshaft S3 to an accommodation coupling, C2, which is split and held together by means of four large bolts, B3, B4, B5 and B6.

Unit System Obtains for the Whole Car—The motor and clutch, making up one unit, leaves the transmission, attached to the live rear axle, as the second unit, and the section, Fig. 5, which is taken through the propeller shaft center, will show

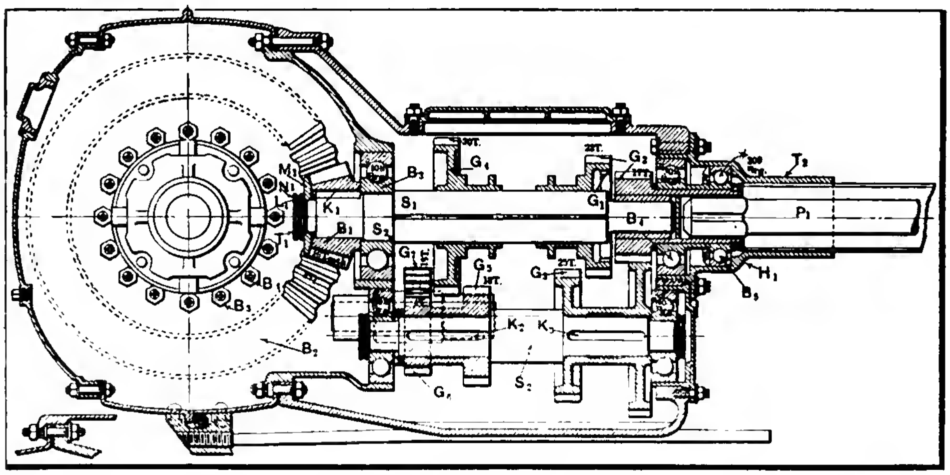

Fig. 5—Section through rear axle and transmission gear, showing annular ball bearings, well-designed gears, and short, stubby shafts

enough of this system to bring out the points to be made plain.

The transmission gear is of the selective type, with three forward speeds and reverse, and direct drive on high speed is brought about by sliding the internal gear G1 into mesh with the teeth of the pinion G2. Hill-climbing gear is let in by meshing the external teeth of G1 with the teeth of G3, when the gear ratio is unity, due to the fact that both gears have the same number of teeth; this leaves the bevel drive as the only means of gear reduction in intermediate speed, which reduction is that due to 53 teeth in the bevel gear and 16 teeth on the mating pinion, and 53/16 = 3.31. Low gear, used for accelerating, is let in by meshing G4 with G5, and the reverse requires that G6 and G7 engage with G4.

The bevel drive, involving B1 and B2, with the latter flanged to the differential housing by bolts B3, B4, etc., is held in rigid relation by the large-diameter shaft S1 and the large annular ball bearing B3, which is a sucking fit, and presses against the shoulder S2, is held on by pressure of the bevel pinion B1, and the end of the shaft is threaded, T1, so that the nut N1 is screwed up against the washer W1, locking the whole system in place. The pinion is prevented from turning by a key, K1, and the nut N1 is locked on by means of a wire in a groove, L1.

The lay shaft S2 is of large diameter, relatively short, hence rigid in the extreme. The gears are keyed on at K2 and K3, are of hardened special steel and of a shape to resist deformation in the process. The prime shaft S3 is a square, and the sliding gears are, like the fixed gears, hardened and of a shape to stay put. At the telescoping joint the gear G2 serves as a sleeve, and annular ball bearings B4 and B5 carry the load. Dirt is excluded by means of the housing H1, which engages the torsion tube T2, which is in concentric relation with the propeller shaft P1, and encloses it completely.

Novelty and the Rear Axle are Companions—The jack shaft S1 is flanged at its end F1, and a supplementary flange, F2, bolted to the flange of the jack shaft, is faced off and fits against a face on the hub member, H1, of the rear wheel on each side of the car. The hub H1 is bored out to take a single annular ball bearing, B1, and this bearing, while it does all the work, is dead on the center line of the wheel, so that it is in a position to assume all the responsibility. The ball bearing is a sucking fit on the reduced diameter of the bronze sleeve S2, and this sleeve fits over the drawn steel tube T1, which is concentric with the jack shaft.

The ball bearing is held securely in place in the most approved manner by means of a locked threaded shell, S3, and the jack shaft, which is of the semi-floating type, is prevented from floating off by the interference of the petticoat P1 of the hub member H1, acting in conjunction with the flanges F1 and F2, they, in turn, being secured in place by means of the hub flange bolts B1, B2, etc., and the rivets R1, R2, etc. The hub cap C1 fits over the flange F2, and is held in place by cap nuts N1, N2, N3, etc., and the appearance of the wheel is somewhat unusual, due to the elimination of the conventional hub.

The brake drum D1 is fastened to the spokes S3, S4, etc., and the drum, while it is of unusual diameter, is also very wide, there being room, side by side, for the two sets of brake shoes S5 and S6. The shoes are faced with asbestos fabric, F3 and F4, which is heatproof and possesses a high coefficient of friction. The shoes are prevented from dragging by the springs S7 and S8, and when it is desired to apply the brakes it requires but a torsional effort on the brakeshaft S9 or the concentric tube T2 for the other set of brakes; this torsion, applied to either set of members, will actuate the respective cams C2 or C3, expanding the bands and applying the necessary pressure to arrest the motion of the car. The brakes are powerful, and, all told, the area of contact of brake shoes is close to 352 square inches, and while the area of surface is not the main factor when effectiveness of brakes is to be determined, it is true, nevertheless, that the life of the brakes will depend upon this area of shoe contact.

Objects Attained in Complete Design—Passing to the front axle, which is of the I-section, with Timken roller bearings, it

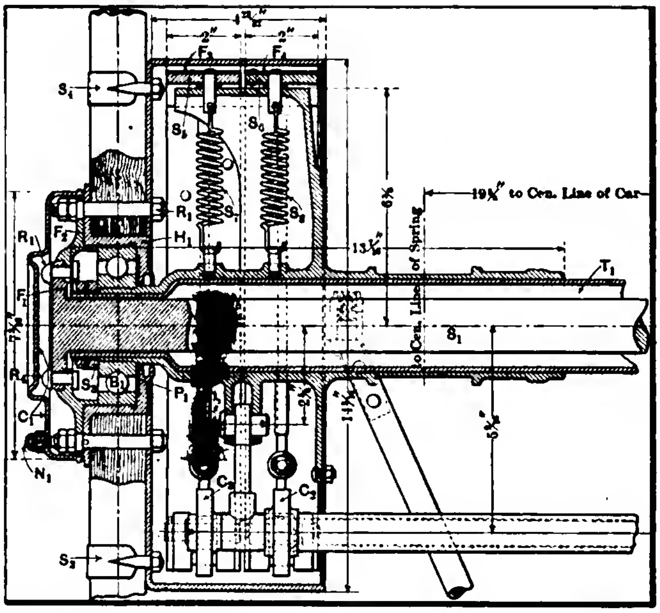

Fig. 6—Section through rear wheel, depicting a single annular ball bearing in the center line of the spokes to take the load, and means for locking at every point

is at once apparent, even without illustrating the axle, that the designer took account of the enormous side strains to be encountered, and what was regarded as perfectly suited for rear axle work was not necessarily in keeping with the requirements as they have to be met in steering road wheel work. This close study of the several parts and units throughout the car is one of the features to be noticed, and it is believed that the car has been sufficiently illustrated in detail to render the whole situation patent.

In conclusion perhaps it will be timely to say a word for standardization, especially of the steering gear, spark advance mechanism, throttle control, foot pedals and side levers of cars. Perhaps it is too much of a subject to ramble into; let it simmer, then, with the simple illustration of how the Marmon spark and throttle lever mechanism is placed on the top of the steering wheel; not without calling attention to the use of a 17-inch diameter wheel. Sitting in the seat, the spark lever is on the right side, and to advance the spark it is necessary to advance the lever. What can be more simple or natural? Likewise, the throttle control, which is on the left-hand side; to advance the throttle it is necessary to advance the lever; advancing the throttle is equal to giving the motor more gas.

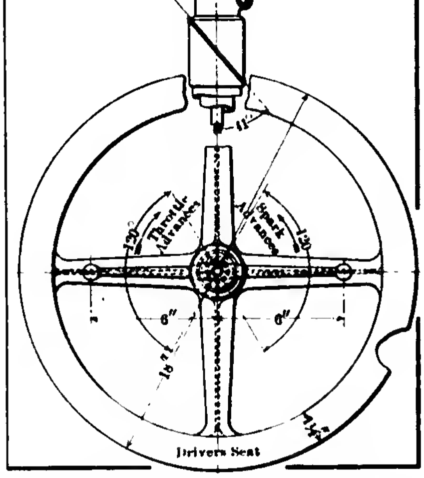

Fig. 7—Plan of steering wheel, with spark lever on right, and throttle on left side, and logical methods of control

Prompt Debut of the Parry

Fig. 1—Touring car for five passengers, ample power, m. b. leather upholstery, carriage finish, and easy riding qualities

THE dawn of another day is but the rhythmic repetition of a normal expectation, but the dawn of another automobile manufacturer is quite another matter; the one is bereft of novelty because it is reoccurring and always the same, while the other is all novelty, due to the ambitious advance over the last effort and the certainty with which a host of uncertainties are mastered.

It is not believed that anyone, even engaged in building automobiles, can reach a fair understanding of the vastness of the automobile industry without spending months, continuously, in quest of information, and in painstaking research, delving deep in hidden recesses, for, as experience is teaching, the largest undertakings, betimes, are hidden away, perhaps in long-abandoned factories that none would have supposed would ever again throb with human interest and bear the brunt of industrial activity on a plane as never before.

The title illustration to this story represents a car that the author had never seen before, and out of curiosity, to some extent, tracked it to its lair. Made in Indianapolis; the "Parry"; rated at 32-36 horsepower, for the motor, which is of the water-cooled type, with a bore of 4 1-4 inches and a stroke of 4 1-2 inches. The cylinders are cast in pairs, of gray iron, with valves in the head as depicted in Fig. 2, and the radiator, which is on the center line of the front axle, is so spaced as to afford room for a commodious fan, so that the air current through the radiator is adequate for the needs.

The tappet rods, for the valve-motion, run in long and well-fashioned guides, have liberal bearings where the rockers engage, and the camshaft, with integral cams, is of special steel, with "ground" cams. The flywheel is large, with an adequate flywheel effect, and the main bearing of the motor, in view of this, is of unusual projected area. The crankshaft is a die forging of "toughened" special steel, has three main bearings of die-cast white metal, and is best understood by glancing at the open crankcase with the shaft in place, as shown in Fig. 3, which also tells that the lower half is not required to carry any of the crankshaft load, since journal caps are used instead.

Fig. 2—Right side of the motor, showing magneto, centrifugal water pump, valves in head, well designed fan, and commodious radiator

The half-time gears are housed in, are accurately cut, set to run on the pitch line and are noiseless. Ignition is by means of a magneto which sets on the right side of the motor as Fig. 1 portrays, and the water pump, of the centrifugal type, is just in front of the magneto on the same side. The steering gear is fastened to the chassis frame at a point between the magneto and the water pump, and the spindle passes through the chassis frame just in front of the anchorage of the rear end of the front spring suspension.

Fig. 4 is of the front axle, and this, in conjunction with Fig. 2 is enough to clearly indicate the character of the steering equipment, taking it as a whole. The linkages and arms are of suitable grades of fabricated steel and straight-line designing is the rule. The front axle is of the I section, die forged in one piece and Elliot type of knuckles add to the line of attractions. The spring perches are integral with the axle, and half elliptic springs are made to take the constant front load.

At the rear of the chassis, owing to the variable nature of the load, the designer has taken advantage of full elliptic scroll springs, besides using an adequate volume of good material. The chassis frame is of steel, hot pressed to a channel section, and the aim has not been to skimp in material at this point; absence of castings or other heavy parts at other points has enabled the designer to see his way clear to afford a rigid chassis frame.

The rear axle, unlike the front, is clearly brought out in Fig. 5, showing a liberally designed tubular construction with a shapely bulb at the center in which the differential gear and the bevel drive is housed. The torsion tube is concentric with the propellor shaft and terminates in a universal joint at the unit transmission gear, back of the motor, resting on the chassis frame.

Referring again to Fig. 5, notice may be taken of the brakes, of which there are two sets, one of which is internal expanding and the other is external construction; both are faced with thermoid, the nature of which is such that any amount of heating such as it will get in this service fails to destroy its good working qualities. The bands are of steel, and the levers are

Fig. 3—Crankcase up side down, depicting crankshaft, three good bearings, and journal caps of strong design

not only of good section but they are fashioned with long bearings, and grease cups are placed at accessible points so that there is no reason why the original noiseless operation of the car may not hold out.

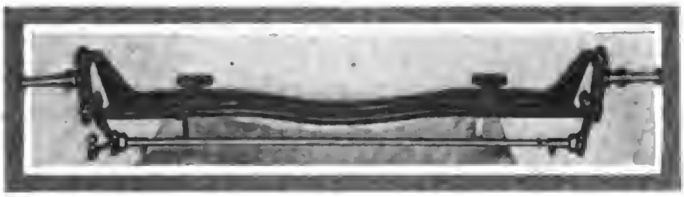

Fig. 4—Die forged I section front axle with integral spring perches, stout knuckles, straight arms and a well-designed cross-rod

Wheels are of the artillery type, made with care from second growth hickory, and the rims for the tires are quick detachable, to fit 32 x 3 1-2-tires. The tread is standard, and the wheelbase is long. There are other nice features to be noticed, as a 17-inch steering wheel, and the side levers, one of which is for the emergency brake, and the other for the three-speed (selective) transmission gear (including reverse), are shapely, strong, work with ease and precision, and are forged from a good quality of steel.

In the direction of long life and stability, there are several points that will receive the barest mention at this time; Fig. 6 showing the chassis just back of the flywheel, presents evidences of this stability. The cross member at this point is deep, and the sub-frame, which serves as a foundation for the motor, terminates at this member. All bearings and supports for the pedal and brakes fasten to substantial members, and no cantilever parts can be seen at any point, so that bending or other distortions will scarcely be a companion to the owner of such a car.

What the author found was the old Standard Wheel Company's buildings, completely filled with machinery and parts for

Fig. 5—Rear of chassis with one wheel removed to present brakes, live rear axle, and full-elliptic (scroll) springs

the making of automobiles, of which the above is but a brief description. Then, there are new buildings in course of erection. The new structures are of steel, and, while they look a little hasty, even so, they are of a substantial character, and the wonder is that they can be put up in such a short time. The entire time taken by this company in doing all this work, including the delivery of model cars, has happened within ninety-six days.

Five Thousand Cars This Year—There is every evidence that the company will put out 5,000 cars this year, which is the number that President D. M. Parry figures upon. These cars will be in two models, *i. e.*, a roadster at $1,285, and a touring car at $1,485. Just what it means to do so many things in less than one hundred days is a matter that can not easily be word pictured, and the camera was used instead, rather with the hope that it would reflect the exact situation. Fig. 7, for illustration, was taken of a big Bowser gasoline tank just rolled into the yard on a flatcar from the nearby railroad. The tank just fits comfortably on the flatcar so that it will not be necessary to describe it further. What any one would want with such a comodious gasoline tank, however, would be difficult to reason out, unless it is that the company intends to test out a considerable number of automobiles.

Magnetos are difficult to procure this year owing to the brisk demand. The Parry engineers, being alive to this situation, have them in hand, one row of which is shown in Fig. 8. In one of the new buildings the line of live rear axles tells still another tale of the early bird and the manner of building automobiles and preparing for the work at the same time; accessory makers,

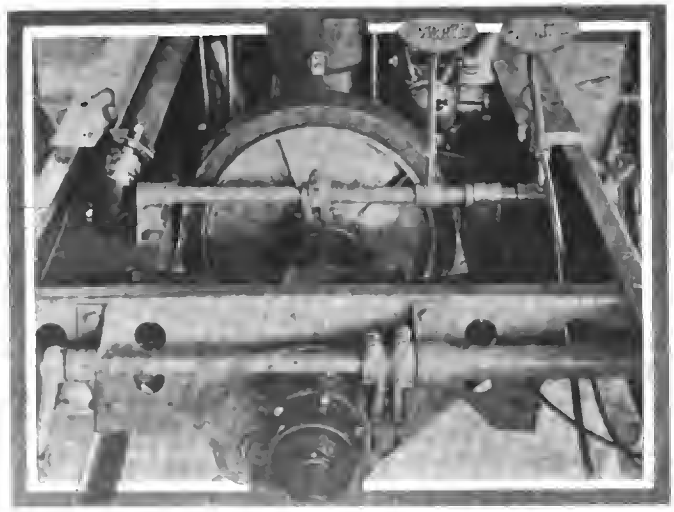

Fig. 6—Chassis just back of flywheel, presenting deep cross-member, universal joint at end of tube, termination of sub-frame, etc.

Fig. 7—A Bowser gasoline tank, on a flat car, in the yard of the Parry Auto Company at Indianapolis

it is plain to be seen, have been called upon to contribute a quota. Fig. 9 depicts one of the long rows of rear axles.

Machining Process Catching Up Rapidly—It might be supposed that, in a new plant such as this, assembling would be the

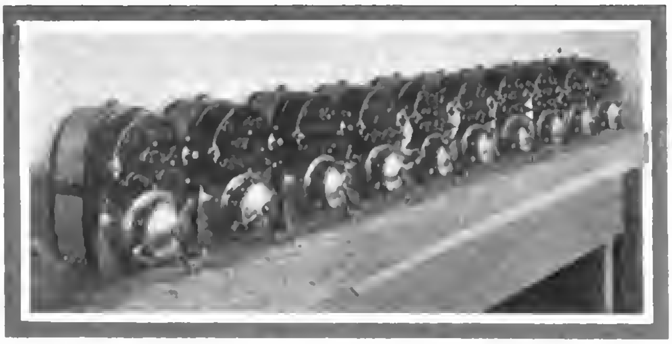

Fig. 8—Magnetos in stock awaiting the propitious time

main activity, but such is not the case. Fig. 10 is of a big new boring bar caught in the act of boring a crankcase, and this is the character of machine tools that is rapidly filling the plant.

In the forge all is activity, parts are being fashioned from bars and billets of steel, and a little to one side the frames are being riveted together. At another point, not far distant, motors are being assembled, and while the building is still ringing with the hammers of carpenters and house-smiths, the motors rapidly assume shape and the sharp exhaust reports of well-timed motors swell the din of noises that are all the more accentuated because the plant is being built and the cars are being made at the same time; what will these men do when they have but one task to perform, *i.e.*, make automobiles?

In conclusion, in view of the statements of President Parry, of the Parry Auto Company, to the author, it is inferred that the ground around the plant, of which there is enough to more than double the present situation from the point of view of

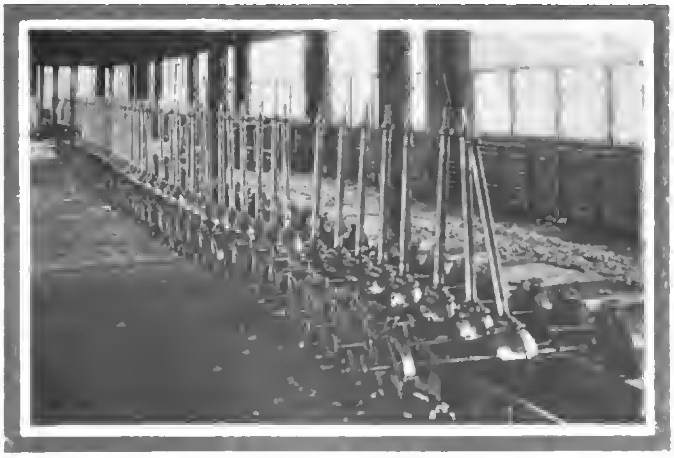

Fig. 9—Live rear axles in rows, in one of the new buildings, ready for instant use

buildings, will be covered with new buildings long before the enterprise is crystallized, and this is but one of the strong situations that center at Indianapolis, which is now an automobile center of first magnitude.

AUTOMOBILE CREATING ITS OWN MARKET

By D. M. PARRY, President Parry Auto Company

The future of the automobile industry is to be regarded in no other than an optimistic way. In the United States in the past ten years about two and a half million vehicles per year have been sold, and a very large percentage of these vehicles will inevitably be replaced by the automobile.

Several hundred thousand machines are now in use, but this number comes nowhere near exhausting the market possibilities. For next year the estimate of production is 200,000 machines, but while this estimate should doubtless be somewhat discounted, there is no question, I think, but what the production will be larger, much larger, than ever before. The automobile means a revolution in means of transit, and this revolution is now in progress. But it cannot accomplish itself in one or two seasons, though in truth it is going forward very rapidly. In fact some seem to think it is moving too rapidly, fearing as they do that too much labor is being abstracted from other pursuits and too much capital diverted from other channels of investment. The readjustment necessarily involved in the development of any extensive industry, such as that of the automobile, is likely to have transient effects here and there which are not desirable, but if the industry itself represents a social need the ultimate results must be to the general benefit.

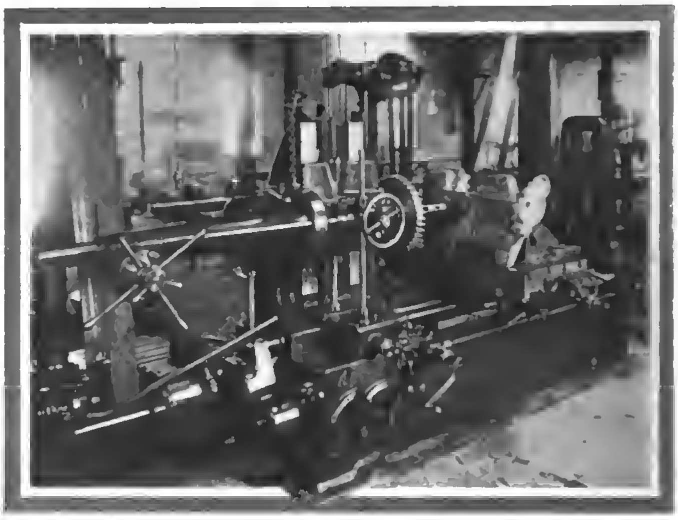

Fig. 10—New horizontal boring mill used in crankcase work for almost every operation

The automobile is the latest word in human progress, and because of its perfection as a vehicle for both business and pleasure, its use is certain to grow. It is not a luxury but a necessity of the times, and the fact that it is a necessity gives legitimate warrant to the use of capital and labor required by it. But granting that the automobile is a thing to be welcomed, the question arises whether there is a too rapid absorption of capital and labor in its production, and we hear some dark forebodings lest a financial panic may ensue because of it.

The automobile industry has reached a vigorous growth, but this is a very large and a very wealthy country, perfectly competent of taking care of any demands likely to be made on it by the development of the industry. The shifting from horse-drawn vehicles, an inevitable process, is going ahead rapidly, but not so rapidly as to test the resources of the country or come anywhere near doing it. From the labor standpoint it is quite evident that the industry is developing many new means of employment and increasing the purchasing power of the thousands at the present moment engaged in it.

NEW ELECTRIC DISPLAYS NUMEROUS DIFFERENCES

ASIDE from the natural interest in things new and different, the electric car recently brought out by the Rae Electric Vehicle Company, Boston, marks a distinct advance in the electrical and mechanical construction of this type of car. The first machine, as shown at the electric show in Boston last month, had at that time run over 16,000 miles. In operation, it is claimed that this car will cover from 100 to 130 miles per battery charge, and irrespective of the number of stops. The latter feature is a new one, previous long radius cars obtaining that mileage only by making fast continuous runs.

By means of the control of this car, just brought out and patented, the starting and accelerating effort is produced by a normal discharge current, thus conserving the energy stored in the batteries and making a larger percentage of it available for mileage, which is the desideratum.

In appearance, as the illustration shows, the construction of the gasoline machine is followed very closely. So, too, with the mechanical features. The power unit is located at the front under the hood, the drive from there is by shaft to the rear axle, the latter being of the full floating type.

Of course, the batteries must be carried, but these are located in the center of the car, below the floor boards of the car. In this way, they do not affect either the appearance of the car, or interfere with the mechanical construction. More than all that, weight is thus placed over the rear wheels, from which they derive increased tractive effort. In addition, the simple lifting of the floor boards allows access to them for charging, inspection, or repairs. This latter feature of accessibility is fully as important as the others.

Not only is accessibility of the batteries made a feature, but the location of the motor and controller forward under the hood is also very accessible. By raising the hood, both are exposed. By removing four bolts, and disconnecting two wires, the power unit is removable. The separation of motor and battery into two separate and distinct units located at some distance apart is also effective in reducing battery leakages.

Sixteen speeds, varying from 3 to 20 miles per hour, are furnished by the controller in its various positions, the operation being such as to vary the field of the motor without external resistances. Noiselessness is made a great feature, being secured by the use of special gears, on short shafts, the latter being mounted upon radial ball bearings. They are well enclosed and run in oil at all times. This enclosing the gears in an oil bath, not only makes for noiselessness but materially aids the longevity of the gears themselves, to say nothing of the matter of reducing friction losses to an absolute minimum quantity.

Floating type of rear axle is an up-to-date feature of gasoline automobiles which has been borrowed to make this quiet running electric more perfect. The absence of driving chains makes the car even smoother and quieter in operation.

In the line of brakes, too, gasoline construction is followed very closely with the best of results. A set of rear wheel brakes,

Rae Electric Victoria, a New Car of Merit

operated by foot lever, is provided, but in addition, there is a shaft brake, controlled through the continued movement of the same lever. Thus, to stop the car, the pedal is pressed lightly. If this is not effective, more pressure puts the shaft brake on, and a determined push of the pedal to the limit of its movement will put both brakes into instant use, resulting in the rapid stopping of the car.

Eighty-inch wheel base is the standard, with a 56-inch tread. Wheels are 32-inch diameter in front and 4 inch in the rear, equipped with either solid or pneumatic tires as desired. The springs are full elliptic both front and rear. The battery equipment is 40 Helios 15 A cells, divided into trays of four cells each, and suspended by steel racks from the laminated wood frame. The individual trays are each removable separately, while the supporting of the racks below the frame results in a very low center of gravity. The usual very complete equipment of tools, lamps, meters, etc., is provided.

Besides the victoria shown, the company will have ready for the 1910 season, equally well-designed coupé and runabout types of the Rae electric car. The factory is located at Springfield, Vt., but offices have been opened at 747 Bolyston street, Boston, from where orders will be filled.

"JACKSON MUD HEN'S" TRIP FROM MICHIGAN TO MAINE

MONDAY morning, November 22, a mud-spattered automobile ploughed through the streets of Bangor, Me., and stopped in front of the City Hall, where Mayor John S. Woodman and a corps of city officials greeted it. The car was the "Jackson Mud Hen," driven by E. P. Blake, of Boston, and Charles Percival, of New York, who for the second time were carrying an official message from the mayor of Jackson, Mich., to the mayor of Bangor, Me. Last year Messrs. Blake and Percival made the same trip in the rain and snow in seven days and eleven hours, and this year, though they started three weeks later, were determined to lower their existing record.

Starting from Jackson at 9:22 a. m., on Wednesday, November 17, in a driving snowstorm, the two men made Toledo, 152 miles, through axle-deep mud and clay without a stop, arriving there at 4 a. m. After a hearty meal the run to Cleveland was resumed with the same road conditions, but a worse storm, the rain turning to snow. Cleveland was reached at 5 o'clock and when food had been partaken of, the 218-mile rough and hilly run to Buffalo was started. At Erie, Pa., a driving snowstorm was encountered which grew to 6 inches of snow by the time Buffalo was reached, in just 12 hours. Albany, N. Y., found them 42 hours ahead of record, and then the long climb over the famous Jacob's Ladder in the Berkshire Hills confronted them. This was made successfully, and midnight brought the "Mud Hens" into Springfield, Mass., where good roads to Boston awaited them. Reaching Boston Sunday morning the car started for Portland, Me., and made their stop for supper at Lewiston.

The all-night ride to Bangor, 165 miles, over the worst roads and mountains lay before the tourists, who successfully made it the next morning at 10:20, beating last year's mark by 2 days 12 hours and 45 minutes and establishing a mark for continuous driving of 123 hours.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

THE DUTY OF THE MOMENT

Lawless and criminal users of the road must be driven from it, and in the accomplishment of this imperative duty of the moment the law-abiding autoists must come squarely into the open and aid in the suppression of the few who cast discredit upon the great army of motor vehicle owners.

Recent fatalities, intermingled with narrow escapes and numerous minor incidents, have aroused in New York City an unreasoning antagonism toward automobiles which has caused thousands of considerate owners great inconvenience and, in some cases, positive persecution. The startling rapidity with which horse-drawn vehicles are being replaced by motor-driven cars brings in its wake a daily chapter of accidents that come from the participation of incompetent drivers in the congested traffic of the metropolis. Along with these are the skillful ones who take chances with slight regard to the other occupants of the streets, the poor pedestrians suffering the most as a natural sequence of their inability always to escape the savage assaults of these murderously-inclined beings who belong behind prison bars.

The New York State law may have answered well enough when the number of automobiles was small and their increase comparatively gradual, but the needs now call for a law which would compel the licensing of every person who sits at the wheel, with penalties severe and a cell in sight for those who trespass upon the rights of other occupants of the highways. A permanent revocation of license should follow a third offence, for this repeated disregard of the law would be proof sufficient that the guilty one was not a suitable person to be entrusted with the driving of an automobile.

And, furthermore, the automobile should carry identification marks which would insure prompt apprehension whenever its steersman violated the law knowingly. The miles-per-hour clause, however, should be eliminated from the statute, for its continuance in a drastic law unquestionably would bring injustice and unfair treatment to many whose only offence would be in exceeding ridiculously low speed limits without harming or endangering anyone.

New York State is a criterion for many other commonwealths, but its automobile law, for various reasons, has fallen behind the times, and the evidence of it painfully exists in the appalling list of accidents in the largest city of the country.

There is a temper which bodes ill for all users of the automobile in the Empire State, unless its State association comes forward with an amended law which shall make possible the punishment of the guilty and their permanent disappearance from the highways. Revocation of licenses and licenses for all drivers, with legible identification both day and night, will rid the highways of those who should not be at large, and will place these runners-amuck where they belong.

Some day the American Automobile Association will be successful in obtaining a uniform federal law that will apply to the whole country. In the meantime, each State will have to do its own regulating, and New York has lagged behind the procession, and, though it has been owing to an involved train of circumstances, behind this commonwealth is, and should be brought up to date in its automobile law.

WHAT OLYMPIA'S EXHIBIT SHOWS

At the great Olympia automobile show, which has just closed in London, and which might well be called *the* foreign show of the year, there was no sensation like last year. Then, it will be remembered that the now-famous Knight engine was brought forth with much rhetoric as to the future disposition of all other types, the scrap heap being the place for them according to the Knight.

After a year's trial, it may be said that the slide valve has held its own, that is, there has been some slight gain in the number of makers which have taken it up. The gain, however, was far from the predictions of the inventor. So, the scrap heap is a good ways off yet.

On the other hand noticeable gains have been made by many forms of construction, and these, too, of a nature which means lowered first cost, reduced upkeep, and greater simplicity. As exemplifying this may be cited the fact that the greatest gain of all was in the class of small cars, powered with four-cylinder engines of from 10 to 18 rating. Nearly all of these had all four cylinders cast in a block, thermo-syphon cooling, fan type of flywheel eliminating the forward fan, improved accessibility of all parts, more attention paid to carbureters and the carburetion problem, and a marked tendency toward the torpedo body even for but two passengers.

PALACE SHOW WILL HAVE 325 EXHIBITORS

NEARLY 325 exhibitors will be in their respective places when the doors of the Tenth International Automobile Show in the Grand Central Palace, New York, are thrown open for the private view at 3 o'clock on the last day of the old year. A better array of automobile and accessory exhibits was never gathered under one roof.

Among the big makers of automobiles who will be present at the Palace are: Premier, Maxwell, Ford, Reo, Stoddard-Dayton, Mitchell, Brush, Jackson, Mora, National and Marmon. The foreign cars will, as usual, be lined up with the Americans, and their ranks will include Panhard, C. G. V., Renault, Fiat, Delahaye, Delaunay-Belleville, Lancia, Clement-Bayard, De Dion, Isotta and Hotchkiss.

Altogether there are 84 exhibitors of automobiles, by far the greatest number ever shown before in New York. Of these 72 are American and 12 foreign. The foreign importers say that they will have the best exhibit of foreign cars ever before seen in this country. The European makers are rushing their 1910 models to completion, and some of them will be shipped to America within the next two weeks.

So great has been the demand for space by the accessory makers that every available square foot of floor space has been brought into play. One hundred and one of the biggest concerns, members of the Motor and Accessory Manufacturers, have been allotted space, and considerably over a hundred independent concerns have had their wants filled. There is no question in the minds of those who have followed the expansion of automobile shows that this is the greatest number of exhibitors ever housed in this country. A feature of the show will be the unusually large number of new makes which have never before been shown.

THE GARDEN VARIETY OF SHOW GIRL

In the search for an attractive poster for the Tenth National Automobile Show, which will be held in Madison Square Garden, New York, January 8 to 15, the managers have hit on one which is not half as bad as the usual run. Instead of the usual winged Mercury or other allegorical figure, the Garden poster is simply a typical American girl, clad in complete automobiling costume. The picture is in keeping with the plans of the committee to make the exhibition and everything connected with it truly national in character.

Madison Square Garden Show Girl

The poster was made by an artist, so it is said, and from a life study. According to the story, the model was a woman well known in automobiling circles, whose pictures have appeared in the trade columns more than once during the past year or two. Because she objected to having a full-face portrait made and would permit only a profile, the artist was much perplexed to find a pose that would take the place of the one he had planned. The young woman, who is something of an artist herself, solved the situation by striking a graceful posture that was immediately approved. She seems to be drawing the beholder's attention to the sign: "Tenth National Automobile Show."

The color scheme is built around the girl's long automobile cloak of brilliant scarlet, with flowing veil and the latest in automobile head-gear. She is expected to be known as "Miss Posy," not because of her attitude, but because she is the real Garden variety of show girl.

MONTREAL SHOW WILL INCLUDE 'PLANES

Montreal, Nov. 27—Montreal will have an automobile show just after the horse show, which would bring it in the week March 26 to April 2. The show will be held under the auspices of the Canadian Automobile and Aero Club. A new feature this year will be the exhibition of a number of dirigibles and aeroplanes. The decision to hold the show was reached at a meeting held recently, and further meetings will be necessary to decide on the details.

MANY CARS DEBUT AT DETROIT SHOW

Detroit, Nov. 29—From the standpoint of varied exhibits the forthcoming show under the auspices of the Detroit Auto Dealers' Association will have but two rivals, New York and Chicago. The Atlanta show set a strong pace in the matter of comprehensiveness, for there were but few less than fifty different makes of cars shown there; but Detroit has already passed this mark. With the show still a month away, fifty-two manufacturers have made application for space, either directly or through their agents.

Detroiters will be able to gain even more satisfaction from the show than has been the case in the past, for here will be shown the progress made during a twelvemonth in the hub of the automobile industry of the world. Last year twenty-six makes of cars were on exhibition. This year there will be more than that number of new ones alone. Cars that will be shown locally for the first time include the Lion, Krit, Warren-Detroit, Detroit-Dearborn, Paige-Detroit, Demot, Anhut, Parry, Paterson, Michigan, Hudson, Studebaker-Flanders, Everitt and VanDyke.

Manager Gillespie and his aides are already busy on the details. Contractor Buelow, who was responsible for last year's decorative efforts, is again in charge, and promises to eclipse all his previous records. The Wayne Hotel Gardens will again be utilized. Every available foot of space has already been taken by exhibitors; in fact, the demand was so great that the customary motorcycle exhibit had to be dispensed with.

DATE APPOINTED FOR HARTFORD SHOW

Hartford, Conn., Nov. 29—At a meeting of the Automobile Dealers' Association last week a permanent show committee for the season of 1910 was appointed, and the show dates were set at from February 14 to 19 inclusive. Fred W. Dart, E. G. Biddle and W. L. Ledger form the committee. Messrs. Dart and Biddle served on the show committee last year, and did good work, as did also Samuel A. Miner, the retired member. The committee has cast longing eyes at the new State arsenal and armory, but it seems to be a case of "nothing doing" here. Foot Guard Hall will therefore probably be the selection, this year as last, and plans for decoration are already under way. The last show was a beauty, from the decorative point of view, but the committee assures the dealers that the coming show will outstrip all previous efforts, both as to beauty and utilization of space.

Grand Forks, N. D.—This city is to have its first automobile show when the farming-implement men of North Dakota and Northwestern Minnesota meet for their annual convention during the first week of February.

TWO BUSY AUTO MAKERS IN ST. LOUIS

St. Louis, Nov. 26—The Dorris Motor Car Company has its plant well equipped wtih special machine tools and such jigs, fixtures, etc., as are characterized to afford interchangeable work, and according to President H. B. Krenning, of the company, the product for 1910 is placed and deliveries will be made on time. Dorris Cars, as they are to be placed in the hands of 1910 users, will have many little refinements, and the care with which the work is done, nearly every part being made in the Dorris shop, offers splendid assurance of satisfaction.

The Moon Motor Car Company, with a shop full of the latest and most capable machine tools, is pushing the work on the new model, which is a "Thirty." Attention is called to the road wheels, which are of special design, with spokes so shaped that they are not only capable of taking the load at the felloe, due to liberal bearing surfaces, but they are fashioned as the Indian's bow, to give at a certain point, the object being to prevent loosening up at the miter.

Among the parts-makers, the More-Jones Company, is now busy on a line of brass, bronze and aluminum castings for use in automobiles. It is the claim of the company that all its work will be up to a high standard, due to the use of new brass, selected aluminum (without scrap), and methods in the foundry that years of experience made possible.

The Medart Patent Pulley Company is specializing on automobile motor flywheels, and due to the character of the mixture used, as well as the process employed, it is found by experience of makers of automobiles who have tried this product, that the flywheels are up to a high standard. The facilities of the company are such that a considerable trade can be accommodated and deliveries are prompt.

The Maxwell-Briscoe Motor Vehicle Company is now located on Twelfth Street, between St. Charles and Olive. This location, in St. Louis, is regarded as advantageous by knowing ones, and "Maxwell," in a big electric sign, heralds the location to all who read.

The Anti-Selenite Company, manufacturers of carbon remover, has been succeeded by the Parham-Goudy Company, and is pushing out for business with its well-established product.

The Petrie-Phillips Company has just received the Parry demonstrating car and is rapidly filling demonstrating engagements, and from appearances, will put out all the cars of this make that can be assigned to this territory; the Parry car is attracting notice.

New London, Conn.—Carruthers & Keeney have opened the Thames garage at 123 Bank street, where they have the agency for the Mitchell. For Mitchell owners they have a proposition to keep cars oiled and adjusted for $5 a month; this includes grinding of valves when necessary, and a complete monthly inspection of the car.

PROSPERITY RULES IN INDIANAPOLIS

Indianapolis, Nov. 26—The Cole Motor Car Company has completed its plans to increase the 1910 output by 300 cars; this concern, due to skill displayed in meeting the wants of discriminating buyers, is finding it quite easy to dispose of all the cars it is in a position to produce, and it prefers to limit the output to that number of cars which can be built right.

The Diamond Chain Company, with largely increased facilities, is putting out more chain than ever, and in its attempt to maintain its high standard, offers aid, of a character which counts, to every user of sprocket wheels and chains, even to the extent of furnishing properly cut sprockets.

The Superior Machine Tool Company, of Kokoma, builder of milling machines, is now, according to Raymond Ruddell, president, preparing to build transmissions, of a high character, for makers of automobiles; details of the plan are well in hand.

NEW KRIT CAR, BUILT IN DETROIT

Detroit, Nov. 27—Though only incorporated two months ago, the Krit Motor Car Company is already established in its factory, with 25,000 square feet of floor space available, and is turning out cars. The company, which is capitalized at $100,000, has for president Claude S. Briggs, and W. S. Piggins, B. C. Laughlin and Kenneth Crittenden as secretary, treasurer and designer, respectively. The officers, together with Charles E. Kanter, F. J. Armstrong, P. F. Luyster, C. W. Whitston, William Reed-Hill, Thomas Harris and Hugh Barry are the directors.

The Krit is a roadster, of rakish lines, 22 horsepower and weighing only 1,250 pounds. The body is finished in a new and distinctive shade of burnt orange. It is low hung, with liberal leg room, and the steering column and levers are on the left side.

The motor has four cylinders, 3 3-4 by 4 inches, cast *en bloc*, and forms a single unit with the change-gear. The clutch is multiple-disc, running in oil. A Bosch high-tension magneto is furnished regularly. The front axle is a neatly designed I-beam, and the rear, being live, is ball bearing throughout. Two sets of internal-expanding brakes are provided. The wheelbase is 96 inches, and the tires 32 by 3. The car complete sells for $800.

NEW YORK TRADE NEATLY VICTIMIZED

Already feeling the Christmas spirit, a number of tradesmen along New York's automobile row responded generously to the appeals of an alleged Western Union messenger boy for donations to the "messenger boys' holiday fund." The fraud was detected hv A. K. Ainlay, manager of the Western Union office at 1771 Broadway, and a general warning has been issued. The offender is described as short and thick-set, about thirty years old, and using the name of James Collins. He is believed to have got away with $180 of the row's hard-earned money.

Stearns Landaulet of the 15-30 Model on a Picturesque Road Near Cleveland

The body, of the combination limousine-landaulet type, is one that has found favor through its roominess and elegant appearance. The photograph also shows the demountable rims which are now stock equipment

Auto Carries Telephone—In a reliability run between San Antonio and Dallas, Tex., D. A. Walker, the president of a local telephone company, was among the entrants, and his car, a Rambler, carried a portable telephone. By means of a long fishing pole with a hook at the end, Mr. Walker was able at any time to make connection with "central," and talk from the instrument in his car. Points ahead were kept informed of the progress of the cars in the run, and in case of break-down messages to bring assistance were sent. One day arrangements were made for the Governor of Texas to be entertained by the tourists.

Trip of Inter-State "Bulldog"—An Inter-State car reached Syracuse, N. Y., Wednesday afternoon after a thousand-mile run from the factory at Muncie, Ind. Fred Fisher drove the car, and the rest of the party was composed of Mr. and Mrs. George J. Arnold, Miss Marion Coogan and Harry S. Brockway. As a result of the trip the George J. Arnold Company has placed an order for 150 Inter-State cars to sell in this district. Frightful road conditions were encountered in Indiana and Ohio, and near Bucyrus the car became so badly bogged that boards had to be used.

Franklin to Run a Garage—The H. H. Franklin Mfg. Co. has leased the former Crosby garage at Montgomery and Water streets, Syracuse, N. Y., which will be used for repair purposes and the display of second-hand cars. The building has three floors, equipped with the most modern machinery and electric power, with a two-ton elevator. It is stated by officers of the company that this is the forerunner of a model garage and show-room which will be erected later. It will contain the offices of the selling force of the Syracuse branch and will be open for business in two weeks.

First Badger Appears—The Badger Motor Car Company, of Columbus, Wis., on Thanksgiving Day shipped its first finished product, a four-cylinder, 30-horsepower Badger, to Webb, Jay & Company, Michigan avenue, Chicago. The company expects to be turning out fifteen or twenty cars a week as soon as its new factory is completed. Considerable difficulty has been encountered in obtaining material promptly. The Badger is finished in Brewster green, with dark-red running gear.

Federal Rubber's Capital—The Federal Rubber Company, of Cudahy, Wis., has increased its capital to $620,000, all paid in, and is contemplating a further increase to $750,000 by January 1. A new building has been completed and put in operation which has a capacity of 250 tires and 500 inner tubes a day. The factory is running till 9 p. m. in all departments. Agencies have been opened in Atlanta, Ga., with the Dunham Rubber Company, in St. Louis with the Phœnix Auto Supply Company, and in Kansas City, Mo., with the Motor Tire & Supply Company.

Atlanta Trophy in New York—The $10,000 City of Atlanta trophy, which was won by Louis Disbrow on his Rainier, has arrived in New York and is on exhibition at the Rainier showrooms, Sixty-fourth street and Broadway. The trophy is of gold and stands 30 inches high. Disbrow's Rainier made the 200 miles necessary to win the trophy in 173 minutes at the rate of 69.4 miles an hour. The car did not make a single stop, but reeled off lap after lap without varying five seconds.

To Make Magnetos—The Whelchel Electric Company, of Anderson, Ind., was organized August 20 to make medium-priced magnetos, and the company's product is just appearing on the market. Bert Whelchel, who has been engaged in magneto manufacturing for seven years, is president of the company. John W. Jones, A. S. McCall and John Rickes, all prominent business men of Anderson, are vice-president, secretary and treasurer respectively. The company has secured a plant at the corner of Third and John streets.

Auto-Car Now Atterbury—The Auto-Car Mfg. Co., of Buffalo, N. Y., one of the oldest builders of commercial cars in America, has changed its name to the Atterbury Motor Car Company. The company's product will continue to be known as the "Buffalo" cars. One object of the change was to avoid the confusion of names with the Autocar Company, of Ardmore, Pa. The Atterbury catalog is now out, showing a complete line of gasoline and electric commercial vehicles.

"Pop" Lowe Sells Midlands—The agency for Midland cars in New England has been taken by the Henderson-Lowe Company, of 117 Massachusetts avenue. This company is composed of Dr. Chas. R. Henderson, who is well known in and around Boston as an automobile enthusiast, and George H. Lowe, familiarly known as "Pop" Lowe. Mr. Lowe has been in the automobile trade for many years, and will have the active charge of the management.

Heating System of Milwaukeean—The new $500,000 plant of the A. O. Smith Company at Milwaukee, Wis., where pressed steel frames and other parts are made, will be heated by a new system invented by Jesse C. Coogan, of Milwaukee. The exhaust from the gas engines in the power plant will be conducted through the factory into radiators filled with water. The system is being installed in several other factories in different parts of the country.

New Muskegon, Mich., Company—The Henry Motor Car Company has been organized at Muskegon, Mich., to take over the business of the Gary Taxicab Company, formerly of Chicago. It is capitalized at $200,000. D. W. Henry, the general manager, says that the company will make for the coming season a thousand cars to sell at from $1,600 to $1,700. A factory building, 110 by 550 feet, has been completed, and deliveries are expected to begin January 1.

Automobile Garage Located Under the Bleachers of a Baseball Park

The new Pittsburg branch of the Studebaker Company is built directly under the seats of Forbes Field, the home grounds of the world's champion Pirates. Naturally much business is done with the Pittsburg fans

"High Wheel" Now "Muncie"—The High Wheel Auto Parts Company has changed its name to the Muncie Gear Works, as the old name proved misleading. In addition to parts for high-wheelers, the company makes differentials, steering and change-gears for standard-type automobiles. The company continues in its former location at Muncie, Ind., with H. L. Warner as manager.

Ferro Foundry Banquet—The Ferro Machine & Foundry Company gave a banquet to its foundry organization to celebrate a record of 1,100 castings a day, which is thought to be a noteworthy feat. The company has built an entirely new machine shop and a new core room, and has enlarged other departments; the working force has been increased from 700 to 1,100 men.

American Trucks Abroad—There seems to be quite a demand for American-built commercial cars abroad. The Grabowsky Power Wagon Company, of Detroit, reports the sale recently of three Grabowsky sight-seeing or passenger cars in Corunna, Spain, and says there are a number of other prospects which may be favorably closed up soon.

Wright 'Planes in Germany—Wrights, Ltd., Berlin, are busy turning out aeroplanes at the works at Reineckendorf, which will be extended as soon as occasion permits. The motors are being manufactured at various German plants, an order for ten having been placed with the Neue Automobil Gesellschaft at Marienfeld.

Meteor Plant Sold—The Bettendorf Axle Company has bought the factory and land of the Meteor Motor Car Company in Bettendorf, a suburb of Davenport, Ia. The building, which was badly damaged in a fire last Summer, will be used temporarily for storage purposes.

IN AND ABOUT THE AGENCIES

Speedwell Agencies—George L. Baker, sales manager of the Speedwell Motor Car Company, of Dayton, O., has secured the following agencies: The Speedwell Company of Cincinnati, 228 East Sixth street, Cincinnati; Electric Construction & Motor Company, Findlay, O.; Central Motor Company, Hamilton, O.; Canton Motor Car Company, Canton, O.; S. Siegert & Sons, Coshocton, O.; Park Motor Car Co., 10215 Superior avenue, Cleveland, O.; Kimmel Bros., 170 North Fourth street, Columbus, O.; Frank Hilt, Tenth and Madison streets, Toledo, O.

Continental Tires, Los Angeles, Cal.—The Continental Caoutchouc Company has arranged for an agency in Los Angeles, Cal. This will be in charge of the E. A. Featherstone Company, 1018 South Main street. The territory will include Southern Colorado, Arizona and a portion of Nevada.

Palmer-Singer, Detroit—The Palmer-Singer will in the future be represented in Detroit by the Bemb Motor Sales Company, which was recently organized. Walter Bemb, who for many years has been connected with the J. H. Brady Company, is general manager.

Rainier, Georgia and Alabama—Paul N. Lineberger, vice-president of the Rainier Motor Car Company, announces the appointment of W. H. Johnston and H. H. Tift as Rainier agents for the States of Alabama and Georgia, respectively, with headquarters at Birmingham and Atlanta.

"Times Square," Philadelphia—The Times Square Automobile Company, of New York, which deals in second-hand automobiles, has opened its fifth branch house, this one in Philadelphia, at 238 North Broad street. The show rooms and repair shop have some 9,000 sq. ft.

Ford, Pittsburg—The Ford Motor Company has opened temporary branch headquarters in the Rittenhouse block on North Highland avenue, with F. E. Weir as local manager, and is seeking a permanent location.

Premier, Reo and Sterling, Pittsburg—The Premier Sales Company, Ltd., which handles the Premier, Reo and Sterling cars, moved December 1 to its new garage at Beatty and Mignonette streets, East End.

Buick, Syracuse, N. Y.—Strait & Shaw have succeeded to the business of the Syracuse branch of the Buick Motor Company, at 223 West Genesee street, with seven counties in central New York as their territory.

Studebaker, Warren, O.—Vanwye and Hitchcock, of Warren, O., doing business under the title of the Hitchcock Motor Company, have secured the agency for the Studebaker cars in Trumbull County, O.

Mercer, Philadelphia—Frank Fanning has secured the Quaker City agency for the Mercer, built by the Mercer Automobile Company, of Trenton, N. J., and is looking for a "row" location.

Hupmobile, Houston, Tex.—J. F. Sigmond has been appointed agent for the Hupmobile, and for the present will be at the Palace Automobile, Company, Rusk and Louisiana streets.

Stoddard-Dayton, Chicago—The McDuffee Company, Chicago, agent for the Stoddard-Dayton, will remove December 1 to a new building at Twenty-third street and Michigan avenue.

Cole and Paige-Detroit, Philadelphia—The Colt-Stratton Company will within a few days establish an agency in Philadelphia to handle the Cole and the Paige-Detroit.

Austin, Atlanta, Ga.—The Atlanta Motor Agency, of 91 North Pryor street, has been appointed local representative for the Austin, manufactured in Grand Rapids, Mich.

Pullman, Philadelphia—While awaiting completion of its building at 257 North Broad street, the Longstreth Company has opened an office at 912 Chestnut street.

Courier, Philadelphia—The Stoddard-Dayton Company, of Philadelphia, has contracted to handle another Dayton product, the new Courier.

Parry, Philadelphia—The Continental Motor Car Company, agent for the Speedwell, will also represent the Parry in Philadelphia.

PERSONAL TRADE MENTION

S. L. Nicholson has been appointed general sales manager of the Westinghouse Electric & Mfg. Co., with direct charge over the sales policy of the entire company. He has been with the company for 11 years, in various capacities.

A. B. Cordner, formerly the head of the A. B. Cordner Motor Car Company, has been appointed New York manager of the Rapid Motor Vehicle Company, and will open an office at Broadway and 64th street this week.

"Billy" Crawford, known in Philadelphia through his work in various endurance runs, in which he drove Franklins and Cadillacs, has signed with the sales force of the Jackson Motor Company.

Eugene R. Mertens, for eleven years associated with the Columbia Motor Car Company and the Electric Vehicle Company, has left for Detroit, where he will continue in the industry.

"Wally" Owen, who drove the Rainier No. 8 in the last Brighton 24-hour race, has signed a contract to sell Rainier cars at the Rainier New York branch, Sixty-fourth street and Broadway.

Frank F. Weston is now manager of the automobile parts department of the U. T. Hungerford Brass & Copper Company, of New York, which makes novelties in brass and copper.

G. Brewer Griffin is now manager of the detail and supply department of the Westinghouse Electric & Mfg. Co., of which he has been assistant manager for six years past.

A. N. Bentley has been made manager of the Southern sales office of the Electric Storage Battery Company, of Philadelphia, in place of H. H. Seaman, resigned.

Charles Robbins, who for several years has been in the industrial motor section of the Westinghouse Electric & Mfg. Co., has been appointed manager of this dept.

GOODYEAR CONTROLS DOOLITTLE RIM

AKRON, O., Nov. 27—The Goodyear Tire & Rubber Company has secured the exclusive American rights to sell the Doolittle demountable-detachable rims, which have shown up well in several racing events of the past season. It is said that during one of the Brighton Beach 24-hour races, in which two cars were equipped with these rims, 54 tire changes were made, some of them taking as little as 28 seconds.

The feature of this rim, which is the invention of Dr. Perry E. Doolittle, of Toronto, is the ease with which tires can be changed on it; an advantage not often found in connection with a demountable rim. The steel rim proper is divided at one point, and is arranged to be expanded or contracted by means of turnbuckles, the first operation removing the rim from the wheel and the second removing the tire from the rim.

As a result of its investigations the Goodyear Company concluded to adopt the Doolittle rim. Negotiations have been finally completed, and within a few days the rims will be on sale at all the Goodyear branches and agencies. Demonstrating wheels are being prepared to show the operation of the rim. The Goodyear Company will also exhibit the rim at all the shows this winter.

RETIREMENT OF W. HILDRETH

CHICAGO, Nov. 27—After seven years of close application to business as vice-president and manager of the Holsman Automobile Company, W. Hildreth has resigned to take a long-deferred vacation. He expects to spend several months in travel and recreation before taking up business again.

Mr. Hildreth's retirement was the occasion of a farewell banquet given at the Chicago Automobile Club to the directors and office employees of the Holsman Automobile Company last Monday. In the photograph Mr. Hildreth is seen at the head of the table, with Mr. Holsman at his right hand.

Seven years ago Mr. Hildreth helped organize the Holsman Automobile Company, and has been its vice-president and general manager ever since. He has always been a firm believer in hill-climbs and reliability runs, and has entered machines in them whenever possible; he has also been a strong advocate of advertising. As a member of the ways and means committee of the Chicago Association of Commerce he was a delegate to the National Tariff Commission convention in Indianapolis, and served on the "foreign trade" and "automobile" committees of the same body. Mr. Hildreth has always carried membership in the various automobile clubs and trade associations.

ANOTHER SYRACUSE, N. Y., FACTORY

SYRACUSE, N. Y., Nov. 27—Unless some unanticipated hitch occurs in the final construction work or the installation of machinery, the new automobile factory, built by Harvey A. Meyer at Wolf and Park streets, will start operations with 100 men soon after January 1. Mr. Meyer has planned to market 200 automobiles next year, and the working force will be increased by degrees with that end in view. The site and buildings involve an investment of $50,000.

The main building is 150 by 60 feet, four stories high, and the smaller one 117 by 30 feet, one story high. Both are of brick and modern in every way. Mr. Moyer has some vacant property adjoining which may be used in the future for more buildings.

NEW CAR TO BURN KEROSENE

DAYTON, O., Nov. 29—Business men here are forming a new concern known as the Kero-Car Motor Company to build an automobile driven, as the name indicates, by a kerosene engine. The new engine is said not to be a freak, either in appearance or operation, closely resembling the standard automobile engine. It will burn, however, either gasoline, kerosene or alcohol.

Farewell Banquet Given by Manager Hildreth to Holsman Office Staff

Information for Auto Users

U. & H. Dual Ignition System—In connection with the latest U. & H. magneto intended for dual ignition, as imported by the J. S. Bretz Company, a coil box and switch for the battery circuit is furnished, to be mounted on the dash. With this magneto practically two systems of ignition are secured. Both use the same set of plugs, thus simplifying the wiring and avoiding the fouling of the idle set, which often occurs when two sets are used.

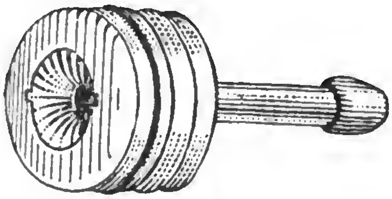
The magneto, like all U. & H. magnetos, is of the true high-tension type; the coil is used only in the battery circuit. The battery timer is incorporated in the magneto, as an integral part. The distributor handles both magneto and battery current, and is of a type which

NEW U. & H. COIL BOX AND SWITCH

prevents the burning of the insulation by sparks playing across when an attempt is made to start the motor on the spark.

The magneto is furnished with the regular U. & H. design circuit-breaker, which is said to require no adjustment, and with the U. & H. timing-pin device, by means of which the magneto is set in correct relation with the motor when first being attached, preventing any likelihood of error in this little understood operation. The magneto shafts are mounted on ball-bearings. This dual system is particularly valuable for motors which are too large to be easily cranked for starting, allowing as it does the motor to be started on the spark even after stops of considerable length.

New Pump Attachment—The lack of universality in pump attachments has at various times been the cause of much confusion, not to say profanity. This trouble will be obviated by a new device just placed on the market by H. K. Austin & Company, Reading, Mass. It is called a patent flexible coupling, from the fact that it is used to couple the pump to the valve of the tire to be inflated. The construction is such that it



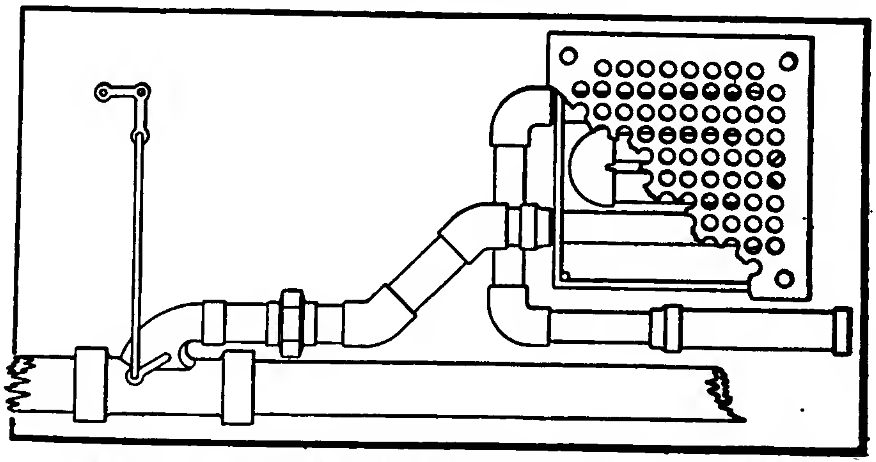
AUSTIN FLEXIBLE PUMP COUPLING

fits all tire valves, and may be used with any make or size of pump. This makes it universal in two ways. This universality is obtained by the use of a rubber nipple, which has a peculiar opening through it. The outer end of this nipple has a rounded or beveled hole leading to an interior hole of apparently one size. This is not the case, however, as the inside expands again, forming a Venturi-shaped interior chamber. Beyond this the aperture is of one diameter through the rubber and the brass cap holding it. The object of the expanded chamber and peculiar shape of the interior is twofold. First, it slips over the tire valve readily, and, second, it not only grasps the latter tightly, but in locking over it the hole is constricted so that air may not escape through it. In this way, if the tire valve was leaking, the sides of the air chamber would lock and hold the air.

New Light Type Front Axle—To go with the light weight rear axle, suited to the lightest types of cars, and described in these columns recently, the Long Arm System Company, Cleveland, have brought out a front axle of similar light weight which incorporates a number of most excellent features. This, as the cut shows, is forged up in a single piece with the spring seats forged integrally. The latter are given a broad space for the spring to rest upon. The thrust of road shocks is well taken up by this construction, while the load stresses are sustained by a single ball of very large diameter. Though shown with ball bearings, this axle may be had with rollers or any form of bearings preferred. The reach rod is placed in the rear of the axle to protect it from inequalities of the road, but on special order they may be had, without additional expense, placed at the front.

"American" Auto-Heater—This is a device for heating the car in Winter by the exhaust gases. It consists of a receptacle 10 inches square by 3 inches deep, fitted in the floor of the car, which contains a coil of radiating tubes. One end of the coil connects to the exhaust pipe, in front of the muffler; a valve is provided which is clamped over a small hole cut in the pipe, without disturbing the fixtures at either end. The valve flap which, when the device is out of use, covers the opening into the coil, swings down into the main exhaust pipe when opened, so as to deflect more or less of the gases into the coil. The other end of the coil has a small muffler to deaden any sound. The heater valve is operated by means of a small hickey which is usually placed on the riser of the front seat.

In any of the closed types of automobile bodies the temperature in zero weather can be brought up to 70 degrees in a few minutes. In an open car, of course, the heat is not so well retained, but by keeping the heater constantly turned on the car can be made quite comfortable. The heater is sold by Flavius C. W. Sudrow, 15 West Swan street, Buffalo, N. Y.

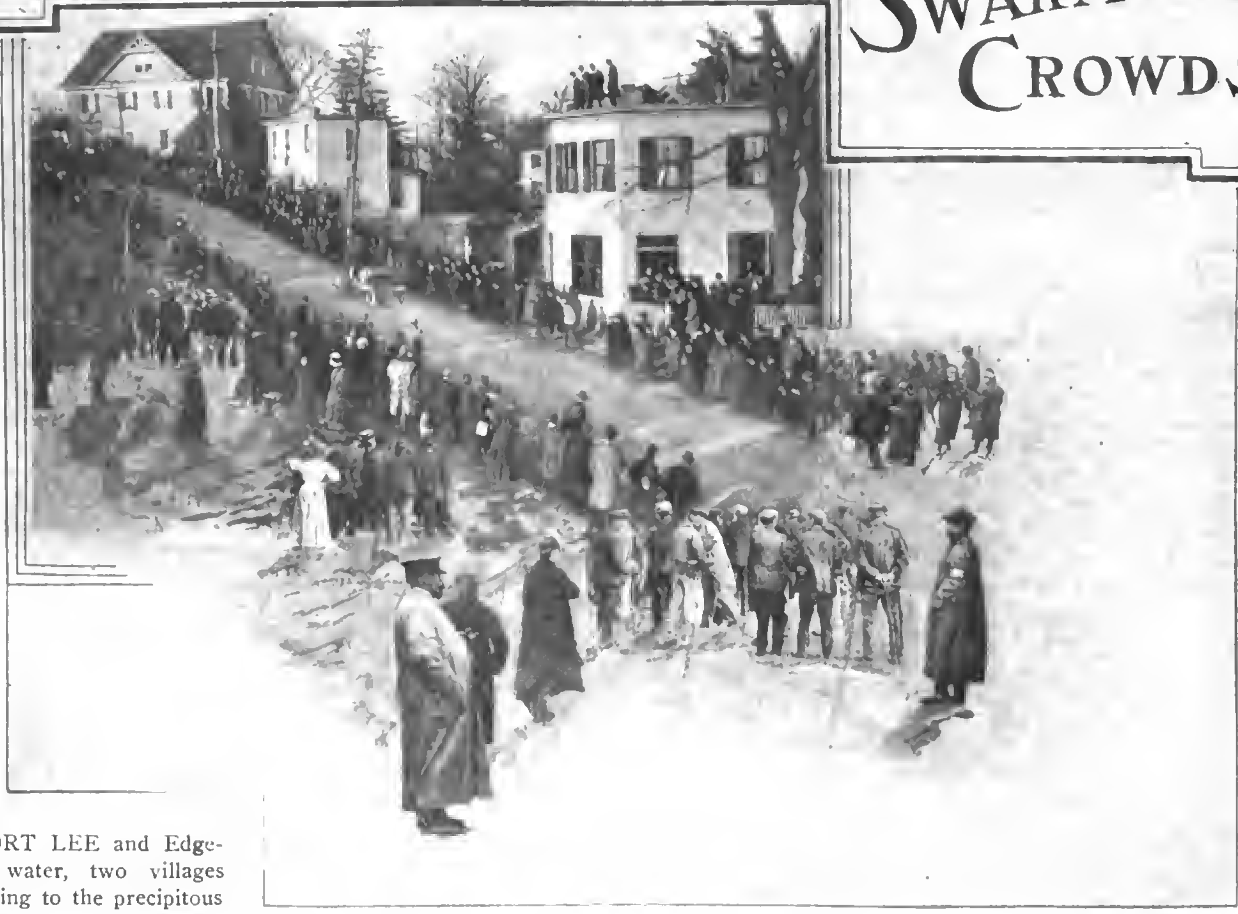


AMERICAN CAR HEATER FOR USE IN WINTER UTILIZES EXHAUST GASES

VOL. XXI NEW YORK—THURSDAY, DECEMBER 9, 1909—CHICAGO NO. 24

THE AUTOMOBILE

FORT LEE'S CLIMB ENDED BY SWARMING CROWDS



FORT LEE and Edgewater, two villages clinging to the precipitous slopes of the Palisades opposite up-town New York, made their appearance on the automobile map last Saturday. The steep and winding road between them, some seven-tenths of a mile in length, proved the best hill-climb course that has yet been discovered on the lower Hudson. Unfortunately, the haphazard management was unable to obtain the exclusive use of the course, and the unruly crowds forced the calling of the event before the higher-powered cars could show their mettle.

When the contest was started, the hill was crowded with spectators attracted by the alluring press notices sent out from the office of the promoter, and also by the clear Winter afternoon which invited outdoor exercise. These spectators were all over the road, and of course in plenty at the most dangerous turns. In such numbers did they overspread the course that those whose business it is to attend automobile races freely predicted a serious accident before the competition concluded. There was slight attempt to keep people off the road, and every car, in climbing the grade, passed through lanes of humanity apparently wholly unconscious of danger.

The hill is a public highway, and there was no way of preventing those who desired to use the road; the contestants say they were told that the hill would be closed to traffic during the contests. It was a foregone conclusion soon after the start that the events could not be completed before dark. Interspersed with the climbing drivers of horse-wagons would come along, and knowing their rights, would insist on going up or down the road. Then everything would come to a standstill until the course had become clear again.

One saving feature of the afternoon was the ingenious time arrangement devised by C. H. Warner, of the Warner Instrument Company. This mechanism automatically indicated the start and finish of each car, and without it, it would have been impossible to time accurately the few cars that did go up the hill.

One driver, after waiting around for several hours, voiced the

Ford, Winner of the Smallest Class, Took the "S" Turn at Speed

On the other side of the road steep slopes led down to the Hudson, glittering under a brilliant Winter sun. From across the river the dwellers in the big apartment houses which line the crest of Washington Heights might have watched the scene through field glasses.

Above the starting line the road swings away from the river into a deep ravine which leads it toward the top of the Palisades. Here a dangerous S-turn, bordered by a stone wall, gave zest to the competition. The grade of this part of the course was said to be 12 per cent. High banks on each side offered vantage points to several thousand spectators, and here and there were perched automobiles, which had made their way to apparently inaccessible crags.

opinion of the rest of the contestants when he said: "I have contributed my last dollar to this sort of thing; they are all alike, no head nor tail. Get the entrance money, and let your friends do the rest. I'm through."

Of the thirty-five cars, including the delivery wagons and trucks, which made timed trials over the course, the National with Kincaid at the wheel was easily the star. The red and black machine, in touring trim, made the ascent in 56.57, the only time recorded under the minute mark for any of the four-wheelers. Chappelle, however, on a little Indian motorcycle, secured a record of 50.15. With the big Fiat and the Simplex trio eliminated by the early close of the competition, the most interesting climbs were undoubtedly those of the commercial cars, which went up loaded to their full capacity. The composition of the loads ranged from pig-iron to pianos.

New York Trade Well Represented—Although held in New Jersey, a good half of the spectators, both *en auto* and on foot, crossed over from the big city opposite via the Edgewater ferry, which plies between One Hundred and Thirtieth street, just above Grant's Tomb, and the village of Edgewater. The salesrooms on "Automobile Row," which nowadays is all Broadway, between Times Square and Seventy-second street, closed their doors early, and their population led the general exodus.

Half a mile north of the ferry house at Edgewater the timers for the start set up their apparatus. The timers' box was a vacant lot, marked off from the road by a wall of rough stone. Finally the road takes a sharp right-angled turn, on a grade of 20 per cent., and leads into the main street of Fort Lee. Fifty yards further on the officials watching the finish line had established themselves on the front porch of Dr. Hueger's residence.

The road surface, of macadam, was generally in good condition. The only noticeable bad spots were at the turn just before the finish line. These might have troubled the big cars, but made little difference to the lighter ones.

Seventy Entries Made Good—The scene just below the starting line left little doubt that the promoters' claim of seventy entries had been fulfilled. The only place for the contestants to line up was the road, by no means capacious. By 1 o'clock, the available margin had been pre-empted by a double line of cars, and the few policemen were hard put to it to maintain a passage for traffic. The big Fiat, which was to have been piloted by Frederick K. Burnham, was the center of attraction. The lifting of the hood over its engine quickly drew a crowd.

The commercial cars turned out in good number, and divided attention with the stripped racers. The Walter truck had four pianos on board, but declined to provide any music. The American was loaded with sugar in barrels, and the two Couple-Gears carried huge crates, supposed to contain furniture, the size of small houses. The operation of the latter was the cause of much speculation, as the driver had at his side a contrivance exactly resembling the controller-box of an electric trolley car. As a matter of fact, these cars were driven by gasoline engines, connected to dynamos; the electric current thus generated runs motors located one in each wheel of the cars.

There was one newcomer which even the denizens of automobile row failed to recognize; it turned out to be the Simons, a one-ton steamer but recently put on the market.

Motorcyclist Bumped a Wall—The motorcycles led off, and put up some fast times. Goerke, on an Indian, was spilled at the final turn, and lost a pedal off his machine. A few minutes later Kledes, on a Reading Standard, came up at a fast clip—so fast, indeed, that he could not get around the turn, and shot off at a tangent. The crowd scattered just in time, and Kledes went head-on into the stone foundation wall of a house on the opposite corner. He managed to slip backward off the machine just before it struck, and escaped with a bad shaking-up. His

Cameron Featherweight On the Stretch Before the Final Turn machine smashed a section of sewer pipe which was lying against the wall, and this probably helped to break the shock.

The commercial cars were the first of the four-wheelers to tackle the climb. Their progress was naturally slow, but by no means uninteresting, as few of the spectators had ever before seen such a demonstration of weight-carrying ability. Owing to some blunder on the part of the starting officials, the Renault and Buick got off at close intervals, and had a neck-and-neck race. The Buick finally caught up and passed the Frenchman just below the final turn. As the timing device could not handle more than one machine at a time, the Buick alone was clocked. Its figure of 2:34.48 turned out to be low enough to win. The Simons, in the same class, was slow on the lower part of the hill, but finished in good shape. For some reason its time, too, was not forthcoming.

Kincaid, Whose National Made the Record, on the Final Turn

The Walter, American, and two Couple-Gears furnished good competition in the heavyweight class, although the former was an easy winner in little more than half the time of the runner-up, the American. The last Couple-Gear was steaming badly at the finish.

Little Cars Made Good Time—Owing to the lateness of the start, it was 2:20 o'clock before the first pleasure cars got their signals. The Ford, driven by J. J. Berthoff, was first away, and its quick dash up the course showed everyone that it was a dangerous competitor. It took the final turn so fast that its outer front wheel could be seen to bend under the strain, yet the car held the road with scarce the semblance of a skid. F. F. Cameron then took up his little air-cooled namesake, but could not equal the Ford's mark of 1:07.15. The Empire apparently went the whole distance on middle gear, and was half a minute slower.

Cameron tried again in the next higher class, and clipped six seconds off his former time, which proved good enough to win. Easter, the featherweight of the drivers present, brought a Buick in second, and Ainslie placed his Hudson with a run in 1:16.20.

After the Auburn and Petrel had made consistent, though not particularly fast runs, Arthur Warren driving a Buick 30 made a dash up in 1:02.70. He skidded badly on the final turn, and gave the spectators assembled there a fright that sent them tumbling back in confusion. Another member of the Warren family drove a Selden into second place, and two Pullmans got the next berths.

In the stripped chassis class four Lancias got a corner on the good places, and crowded the Nagant, a newcomer to the metropolitan market, into fifth position. The little Italians all made good runs. F. Strobel turned out to be the winner. Harry Fosdick was the slowest, and in accordance with an ante-race agreement was forced to set up the dinner for the other members of the team.

Kincaid Set the Best Mark—James Westervelt, with a Knox, was the leader-off in the $2,001-$3,000 class, but could not place himself. Tom Kincaid, the next up, electrified the crowds with a dash that was clocked in 56.57. His driving was the prettiest performance of the day, and he seemed to be able to hold his car on the road no matter how great the speed or how sharp the turn. After several slower machines had made the climb, Richard Carter with a Selden and Frank Hurmance with another National made trials which netted them third and second places respectively.

During the progress of the meet conditions had been steadily getting worse. The police force was entirely inadequate to hold the crowds in check. At the final turn into Main street, Fort Lee, two lone policemen attempted in vain to keep spectators from invading the road. To add to the confusion at this point, two men from the lighting company attempted to replace a carbon in an arc-light suspended over the middle of the course. After several ineffectual attempts, they broke the globe of the light and scattered fragments of glass on every side.

Drivers of trucks and wagons insisted on crossing and traveling up and down the course from time to time, often narrowly escaping collision with the competing cars. Between nearly every trial one or more non-competing cars would attempt the climb. When the turn of the fast cars came, therefore, Referee A. H. Whiting and Alden McMurtry of the Technical Board decided that it would be courting danger to allow them to start, and the climb was accordingly declared off.

As soon as this decision was announced a dozen of the cars which had been waiting their turns began a mad free-for-all scramble and accidents were narrowly averted. Summary follows:

Confusion Reigned Supreme at the Starting Line in Edgewater

Couple-Gear Gasoline-Electric Three-Ton Truck—Loaded

Car and Driver.	H.P.	Time.
GASOLINE STOCK CARS, SELLING AT $850 OR LESS		
Ford, J. J. Berthoff	20	1:07 15-100

Knox, J. Westervelt	38	1:26 90-100
Walter, W. Walter	24	1:43 50-100
GASOLINE STOCK CARS, $3,001 TO $4,000		
American, L. C. Howard	40	1:04 47-100

AGAIN SAVANNAH

Savannah, Ga., Dec. 6—Savannahians feel so confident now of having another big race that the convicts are being put to work to put the course in better condition. If another race is held a whole new course will be found here, and much faster time will be possible. Instead of having twenty odd turns only seven are now to be found. The lengthening of Ferguson avenue straightaway to LaRoache avenue offers a five mile stretch. This also allows the worst turns of the old course, at Isle of Hope, to be done away with. Then the loops around the County farm will be eliminated and some of the curves in Whitefield avenue will be cut out, making this practically a straightaway, while an even more radical change than any other will be in leaving out the White Bluff road and using Waters road instead. The change will shorten the course from twenty-five miles to eighteen or twenty miles, which is long enough.

It has been decided by the Savannah Automobile Club to have the endurance run to Jacksonville the latter part of next March. The Jacksonville club and a local paper will cover that end of the run. It has also been decided to run to Columbia, S. C.

WORCESTER WILL HAVE WINTER RUN

Worcester, Mass., Dec. 6—The date of the second annual endurance run of the Worcester Automobile Club has been fixed as December 17. The rules will be substantially the same as last year, which called for five runs of about 40 miles each over rough and hilly Massachusetts roads.

Penalties are imposed for lateness at the Worcester control, for road repairs, adjustments or replacements, and for the repairs necessary, as judged by the Technical Committee, to put the car in perfect condition after the finish of the run.

AWARDS IN FLORIDA ENDURANCE RUN

Tampa, Fla., Dec. 4—The contest committee of the Tampa *Times* has officially announced the winners in the recent Tampa-Jacksonville-Tampa endurance run. First prize in the touring class goes to Mr. Williams, who drove an E. M. F., and second prize to Perry G. Wall, Chalmers-Detroit. In the baby tonneau class Dr. J. S. Helms with a Premier won the first prize, and Henry E. Snow, Chalmers-Detroit, the second. Ambrose Davis and V. A. James, with Maxwells, took the runabout prizes.

REPUBLIC CO. LICENSED BY SWINEHART

Youngstown, O., Dec. 6—The Republic Rubber Company, of this city, has taken out a license to make crosswire truck tires under the patents of B. C. Swinehart. These tires will be made in all sizes, and will be fitted to the wheels by clincher side flanges bolted on. This will permit a driver to change tires in a few minutes, without the use of special tools. B. C. Swinehart, formerly vice-president of the Swinehart Company, will take charge of the Republic Company's new truck tire department.

Where the Timers Officiated at the Finish Line, Fort Lee

James J. Jeffries and Carl Fisher Took a Spin Around the Indianapolis Speedway in the Latter's Stoddard

INDIANAPOLIS SPEEDWAY NOW READY FOR ITS REOPENING

INDIANAPOLIS, IND., Dec. 6—The initial meet over the new brick course of the Indianapolis Motor Speedway will be held December 17-18. Sanction has already been granted for the meet by the A. A. A., and plans for the program are progressing and will be completed this week.

It is expected that the brick pavement will be completed Wednesday or Thursday of this week, and after standing two or three days, will be thrown open to practice for the drivers who are to compete. The completion of the pavement will be marked by sealing it with a gold-plated brick, which incidentally, will mark the last of a total expenditure of about $700,000.

In addition to the brick pavement, many other improvements have been made since the August meet. A three-foot concrete wall, twelve inches thick, has been built around the course and the stands have been enlarged, while others have been built.

Ernest A. Moross, director of contests, states that the coming meet will include speed trials of practically all usual racing distances from one-fourth to 1,000 miles. They will include one-fourth, one-half and one mile, as well as one kilometer trials. In the match events, there will be races for cars of all classes coming under the rules of the A. A. A.

The coming meet will not be held in the expectation of it being especially profitable from the standpoint of the speedway management. The management, however, hope to close the year with the record of holding all of the records recently established at Atlanta.

Lewis Strang has shipped his 200 h.p. Fiat and Walter Christie his Christie car to this city, and these drivers will be among the first to practice over the course. Harroun, Aitken, Oldfield, Chevrolet, Burman and other well-known drivers are expected to compete. Attractive prizes will be hung up and the meet promises to be of more importance than was the August meet.

During his recent visit to this city James J. Jeffries had a tryout of the new course in company with President Carl G. Fisher, who gave the champion pugilist the fastest journey he has ever had in an automobile, equalling Jack Johnson's best records.

QUAKERS ABANDON NEW YEAR'S RUN

PHILADELPHIA, Dec. 6—At a meeting of the contest committee of the Quaker City Motor Club last week it was decided to abandon the annual New Year's run, which it was decided had become more of a test of the endurance of drivers and passengers than of the competing cars themselves. A number of entries had already been received, but so many of the ease-loving Quakers expressed their preference for warm firesides that the committee decided to spend New Year's day at home.

The $7,617.34 balance remaining after all expenses were paid was last week handed over to the four beneficiary institutions by the committee which managed the recent Fairmount race.

Now that the Quakers have abandoned their New Year's run, the Century Motor Club, Philadelphia, infant automobile organization, has decided to have a single day's roadability run on Saturday, January 1. The route selected will include Wilmington, Chester, Norristown, and Doylestown—about 150 miles.

CHALMERS WINS A $1,000 MATCH

PHILADELPHIA, Dec. 6—Leading from the start, Harvey Ringler, in his Chalmers-Detroit, on Saturday last at Point Breeze, easily won a 50-mile thousand-dollar match race from Ira Brown, president of the Brown Auto Top Company, who drove a Buick. The latter was in trouble almost from the start, first a balky magneto and then a leaky radiator keeping him back. The numerous stops necessary to remedy the trouble put the Buick so much to the bad that at the completion of his thirty-fourth mile, when nine miles behind the Chalmers-Detroit, Brown withdrew, hopelessly beaten, and abandoned the prize.

CADILLAC WINS OKLAHOMA RACE

OKLAHOMA CITY, OKLA., Dec. 1—The cup offered by the Oklahoma Automobile Association for the run from Oklahoma City to El Reno and return was won by Norman Smith, driving a Cadillac, who covered the 67 miles of rough roads in 1:53:13. A Franklin driven by Colcord finished second in 1:57:00, and an Oldsmobile with Baird at the wheel took third in 2:02:00. There were several accidents. The Ford entry turned turtle, and its driver, Fred Winkle, is now in the hospital. The Velie and Salters were ditched and put out of the running early in the race.

Indianapolis Dirigible Shed, 290 by 80 by 75 Feet

LOCAL ORDINANCES YIELD TO STATE LAW

PHILADELPHIA, Dec. 6—Where a local automobile ordinance conflicts with the new State law, the latter takes precedence, is the opinion handed down by Judge William B. Broomall, in the Delaware County Court at Media, in the case of Borough of Swarthmore vs. Wilmore B. Taylor. At about 7.45 on the evening of July 21 last, Mr. Taylor was operating his car in the borough mentioned, when he was arrested by a constable for driving without lights. Taken before Justice of the Peace Charles W. Burnley, Mr. Taylor was fined five dollars and costs, which he paid under protest and took an appeal. He contended that under the State law, which provides that lights shall be carried "from one hour after sunset to one hour before sunrise," he was not guilty, as the sun had set but half an hour.

The prosecution insisted that the borough ordinance, which required that automobiles operated on Swarthmore's streets and roads shall carry lights "from sunset to sunrise," had been violated. Attorney J. B. Colahan for the defense, cited the State law on the subject, and further called the attention of the court to that section of the act which reads: "No city, county, borough or township shall have power to enforce or maintain ordinances, rules, or regulations inconsistent with .... this act, ... and all such local ordinances, rules or regulations now in force shall expire and shall be null and void."

In his opinion Judge Broomall calls attention to the confusion and trouble which would result if each borough and municipality had different and changing regulations on the subject, and says: "That the State has the power to legislate upon the police regulations of its highways is without question." He then quotes the State regulation as to carrying lights from one hour after sunset to one hour before sunrise, and says: "This confers upon drivers of vehicles the right to proceed without lights during the remainder of the 24 hours. . . . Therefore, the (borough) ordinance, in imposing a longer time for the display of lights than that which is imposed by the (State) act, is manifestly inconsistent with the spirit of the statute and is consequently invalid.

CHICAGO COUNCIL MAY REGULATE TAXICABS

CHICAGO, Dec. 6—An ordinance drawn at the suggestion of City Sealer Kjellander has been recommended for passage by the judiciary committee of the Chicago City Council. The ordinance eliminates the hour rate, except by contract, and directs that the taximeters be inspected annually. The text follows:

"In the absence of a contract to the contrary, no person, firm or corporation owning, operating or controlling any taxicab shall let the same for hire or reward for a fee or charge to be fixed and determined by the hour or fraction thereof, but the fare demanded shall, excepting for waiting time as herein provided for, be computed by the distance traveled and according to the following rates: "For the first one-half mile or fraction, 40 cents. For each four minutes of waiting, 10 cents."

WATCH YOUR TAIL-LIGHT IN HARTFORD, CONN.

HARTFORD, CONN., Dec. 6—According to automobilists residing in other towns who have been arrested in this city for not properly illuminating the rear number at night, Hartford is about the only place in Connecticut where this feature of the new State automobile law is enforced. But Hartford means to curb the speeders and intends that everybody shall know it.

MASSACHUSETTS WILL INSPECT TAXIMETERS

BOSTON, Dec. 6—Acting under the provisions of the law relative to the testing and sealing of taximeters, passed by the Legislature last June, Daniel C. F. Palmer, State Commissioner of Weights and Measures, has made preparations for the inspection and test of the meters on motor cabs throughout Massachusetts. The law (Ch. 541 Acts of 1909) provides that the testing and sealing of such devices shall be performed by the commissioner of weights and measures of the commonwealth and not by the sealers of weights and measures in cities and towns. All such devices shall be tested as to the correctness of measures and values indicated by them, and the commissioner is empowered to make such rules as he may deem necessary.

To carry out the provisions of the law the State Commissioner has had laid out three measured courses of a mile each in Boston and will have similar courses laid out in the other cities where taximeter cabs are in operation. The Boston courses are on Beacon street, Massachusetts avenue and Columbus avenue.

They are marked permanently by metal plates in the curbing, these plates showing the beginning and end of the mile, the thirds, quarters and sixths. It is his plan to start a taxicab at the beginning of one of these courses and run it over the full mile, noting the tariff registered at the half mile, and at the quarters in what is known as the first tariff, and at the thirds and sixths in the second tariff. Under the first tariff the charge for the first half mile is thirty cents and for each succeeding quarter mile ten cents. Under the second tariff the charge for the first one-third mile is thirty cents, and an additional charge of ten cents is made for every succeeding sixth of a mile.

If the meter proves to be correct the commissioner will place upon it a lead seal in such a manner that the meter head cannot be removed or detached without breaking the seal.

It is believed that Massachusetts is the first State to undertake the testing and sealing of taximeters, although New York and some other cities have undertaken their supervision and testing

MILWAUKEE MAY TAX ALL VEHICLES FOR ROADS

MILWAUKEE, WIS., Dec. 6—Erich Cramer Stern, Milwaukee's youngest alderman, has issued an interesting defense of his proposed ordinance to tax all classes of vehicles. If the people of Milwaukee want better streets, more pavements and a better maintenance of existing pavements, he says, a vehicle tax is necessary, because the sources of revenue for this purpose now produce too little. The abutting property owner pays for the initial improvement of making a new street, but after that he should not be made to contribute or bear the entire cost of maintenance until a permanent pavement is laid. The property owner usually gets very little use for his contribution, says Alderman Stern, and it is fair that those who use streets should maintain them.

WISCONSIN UPHOLDS FINE FOR ROAD OBSTRUCTION

RACINE, WIS., Dec. 6—The circuit court at Racine has upheld the Racine municipal court in its action of fining a man for obstructing a roadway. Ernest Nowak, a Caledonia farmer, held the center of a narrow road for more than an hour when asked by Henry Plow, of the Mitchell Motor Car Company, for room to pass, keeping a pace of about four miles an hour. Plow brought suit for malicious obstruction of the highway, and Nowak was fined $10 and costs. This decision has been upheld.

LATHAM AGAIN BREAKS AEROPLANE HEIGHT RECORD

RHEIMS, FRANCE, Dec. 1—In a forty-mile gale Latham to-day piloted his Antoinette monoplane to a height of 500 meters, or over 1,600 feet. The record was officially observed by the Aero Club of France, which makes it a world's record. It equals, and probably surpasses, Orville Wright's unofficial record

Latham's Graceful, Birdlike Machine, in a High Flight

at Berlin on October 2. Paulhan is unofficially credited with having attained a height of 600 meters, nearly 2,000 feet, on November 20, but was not officially observed. Latham's Antoinette has been purchased by Hayden Sands, an American amateur, who has been taking lessons in flying for some time.

The rivalry between Latham and Paulhan is very keen, and some method of automatically determining the height attained will have to be invented. The present system, under which army officers observe the machine and take its altitude by triangulation, has many possibilities of error and is inaccurate at its best. It is thought that some form of self-recording barometer can be devised, to be carried on the aeroplane, and calibrated with reference to an official barometer on the ground.

Aviator Fernandez a Victim of His Imprudence

NICE, FRANCE, Dec. 6—Antonio Fernandez was instantly killed to-day by the collapse of a biplane of his own construction, in which he was making his first long flight. The accident appears to have been due to the inexperience and recklessness of the aviator, who, despite the objection of his mechanic, patched up a defective part of the machine with twine before attempting the flight. After going 200 meters, he took a turn too sharply and the machine tipped over, striking the ground with terrific force. The aviator was crushed beneath the motor.

The Fernandez machine had points of resemblance to the Wright and Curtiss biplanes. It was present at Rheims, and was later exhibited at the Paris Aeronautical Salon.

SANTOS-DUMONT TRIES BIGGER MOTOR

PARIS, Dec. 2—Since his record-breaking cross-country flights a few months ago not much has been heard of Santos-Dumont. He has not been idle in the meantime, but has been preparing his diminutive flyer for still more important performances. In place of the two-cylinder opposed engine that Darracq supplied and afterwards made the subject of a lawsuit, a four-cylinder Bayard-Clément of 45 horsepower has been fitted. In proportion to the supporting area it is the most powerful motor ever carried on an aeroplane, and should give remarkably high speeds. The first trial, though ending rather badly, tended to prove this. The aeroplane was taken out at Issy-les-Moulineaux, rose immediately and set off at such a speed that it had to be brought down quickly in view of the smallness of the ground. Being in danger of running into a fence, Santos-Dumont braked the wheels with his feet, causing the aeroplane to stop so quickly that it stood up on its nose, breaking the propeller and damaging the wings. Repairs will be made in a few days and flights continued at Saint-Cyr, where the aviator will have abundant room.

Paulhan Takes His New Farman Biplane Overhead

The Bayard-Clément engine is a four-cylinder in one casting, with valves on one side, and a one-piece copper jacket for all but the valve pockets, the jacketing of which is cast with the cylinders. The engine was never intended for such a small aeroplane as the Santos-Dumont, but as it has been found that this aeroplane is capable of lifting it, the fastest flying machine in existence has been secured. With the Darracq engine of 25 horsepower a very high speed was obtained, with the Bayard-Clément of 45 horsepower an increase of ten m.p.h. is counted on.

News of Aviators in Many Parts of France

Louis Blériot has fixed upon the Southwest of France, three miles from Bordeaux, as the best place on which to establish aeronautical headquarters. He opens school on December 1 with twenty pupils, who will be taught to fly the little monoplanes over a six-mile course. The district is a vast heather-covered plain with a mild climate and an atmosphere that is rarely disturbed by air currents and boisterous winds.

Sheds and rooms for the pupils have already been erected, but during the Winter a complete factory capable of accommodating 400 workpeople, will also be put on the edge of the plain. At present the Blériot machines are being built in the Blériot workshops in the suburbs of Paris, where the maximum output is one a day. As there are several hundred orders on hand, and the number is likely to increase, it is necessary to look for larger quarters. Blériot has already signed contracts for the erection of buildings for his aeronautical school to the value of $30,000.

Many Prospective Meets Next Summer

The plain, which can be cleared to make it suitable for aeronautical work, is open to other aviators, and will doubtless shortly become as important an aeronautical center as Mourmelon, in the Chalons district. Bordeaux has already decided on an aviation week over this plain next September, when there will be a Grand Prix of $20,000 and other prizes totaling altogether $100,000. In all probability Bordeaux and Rheims will be the two great aviation meetings of the year, the one held late in September, and the other early in August or late in July. Rheims has decided to repeat its program of last year, with an addition to its prize money which will carry the total to $80,000.

French Army Officers Observing Height of Aeroplane

WASHINGTON INCLUDES AERO EXHIBITS

Washington, D. C., Dec. 6—A striking feature of the automobile show to be given by the local dealers at Convention Hall during the week beginning January 24, will be a comprehensive exhibit of aeroplanes. The matter was discussed at the last meeting of the dealers who are promoting the show and the suggestion to have such an exhibit met with instant favor. The Government has a number of aeroplanes in the Smithsonian Institution and a request will be made for their loan.

BALTIMORE'S GROWING AERO FUND

Baltimore, Dec. 6—The Finance Committee of the Baltimore Aero Club has raised $20,620 of the $50,000 guarantee fund for the next international aviation meet. This fund was given a boost by a subscription of $5,000 from the Baltimore and Ohio Railroad Company. The committee further announced that it has several large subscriptions in prospect. Many of the proposed subscribers have been out of the city for some time and this has caused a delay in the committee's work.

WANTED—AVIATORS, CHENANGO, N. Y.

Norwich, N. Y., Dec. 6—By voting to admit aviators on equal terms with automobilists, the Chenango County Motor Association believes it has put one over on other similar organizations in the State. This action was taken at the annual meeting. No aeroplanists have yet applied for membership.

ADVERTISING MANAGERS ORGANIZE

Fourteen representatives of the advertising departments of A. L. A. M. makers held an organization meeting at 7 East Forty-second street, Monday, with the result that a trio consisting of Arthur N. Jervis, Charles W. Mears, and K. P. Drysdale were designated as a committee to perfect permanent plans. It was made clear at the outset that nothing should be done to restrict the initiative or the freedom of action on the part of any of the members. It is the belief that much good can be accomplished by an interchange of ideas and period discussions of problems of mutual interest. R. H. Johnston was elected temporary chairman, and C. A. Stein was named as secretary. The roll call was as follows:

Arthur N. Jervis, American Locomotive Company; K. P. Drysdale, Cadillac Motor Car Company; H. W. Ford, Chalmers-Detroit Motor Company; Guy Hutchinson, Corbin Motor Vehicle Corporation; B. Rockwell, Maxwell-Briscoe Motor Company; H. L. Foote, Peerless Motor Car Company; George H. Davis, Pierce-Arrow Motor Car Company; H. A. Linehard, Pope Manufacturing Company; C. W. Wooster, F. B. Stearns Company; C. A. Stein, Stevens-Duryea Company; E. Leroy Pelletier, Studebaker Automobile Company; F. L. Faurote, E. R. Thomas Motor Company; R. H. Johnston, Waltham Manufacturing Company, and Charles W. Mears of the Winton Motor Carriage Company.

Colonel Frank Marston, of San Francisco, in His Locomobile

WISCONSIN WANTS COBE RACE

MILWAUKEE, WIS., Dec. 6—President M. C. Moore of the Wisconsin State Automobile Association has submitted to the racing board of the Chicago Automobile Club two proposed courses for the next Cobe trophy race. Both are in Walworth county, which touches the Illinois line at its southern boundary. Whitewater, the nearest city, is approximately 85 miles from the center of Chicago, and 45 miles from Milwaukee.

One course, as laid out by President Moore and H. L. Halverson, vice-president of the W. S. A. A., who resides at Whitewater, is practically square and four and one-half miles long, with an extra-wide and recently improved road-bed. The other course is six miles long, one leg of which touches the southeast limits of the city of Whitewater.

The road-beds are wider than the ordinary Wisconsin country road and are particularly free from gullies and deep ditches at the sides. Another good feature is that there are no villages or cities to interrupt the free use of the road, every part of the distance being in the country.

Janesville, Beloit, Elkhorn, Fort Atkinson, Delavan, Jefferson, Burlington, Racine, Kenosha and numerous other towns and cities of pretentious size are within easy striking distance.

The Wisconsin association is anxious to get the Cobe race and will do everything in its power to arrange the details, so the C. A. C. will have only to hold up its end. Even if the Cobe race should go elsewhere, the association plans to hang up a valuable cup for competition on one of these courses.

WHERE THE AUTO DEMONSTRATED

MORRISTOWN, N. J., Dec. 5—A fire that started in the general store of John M. Allen in Peapack, this morning, destroyed two other stores and two residences before it was checked. The Peapack Fire Department, unable to cope with the fire with its gasoline pump, asked aid of neighboring towns. The fire companies of Far Hills, Bernardsville and Mendham responded. Chief Engineer J. Fred Runyon, of the Morristown Department, was asked to aid. He took the automobile chemical engine to Peapack, covering the 13 miles to the fire in 21 minutes.

The Morristown men relieved the country firemen, who were almost exhausted, and took a stream into the residence of Philip Todd, and after a hard battle stopped the flames.

Western Canadian Life has one feature that rather surprises the newcomer, and that is the popularity of automobiles. In the Winnipeg district alone there are 800 cars on the register. Splendid new highways run for miles in every direction. Even the prairie trails make good running for a well-sprung car. Calgary has 350 cars to its 25,000 population, and Edmonton 270. At present cars of American makes predominate, mostly of four cylinders and between sixteen and twenty horsepower.

BLUE BOOK SALES THREE MILES LONG

An enthusiastic statistician in the office of the publishers of the Official Automobile Blue Book recently compiled some interesting figures to present on the sales of that well-known work for 1909, showing how great has become the popular demand for this exclusive and very complete, to say nothing of accurate, road guide, covering as it does the whole "navigable" part of the country.

He ascertained that it required the skins of 1,950 cows to supply the leather for the 25,000 books which have been sold. He also figured that if all of these books were placed one on top of the other it would make a column 2,833 feet high, or over four times the height of the Metropolitan Life Building, the highest building in the United States. Placed lengthwise, these books would make a path three miles long, running from Lincoln Square, Sixty-sixth street and Broadway, to Grant's Tomb.

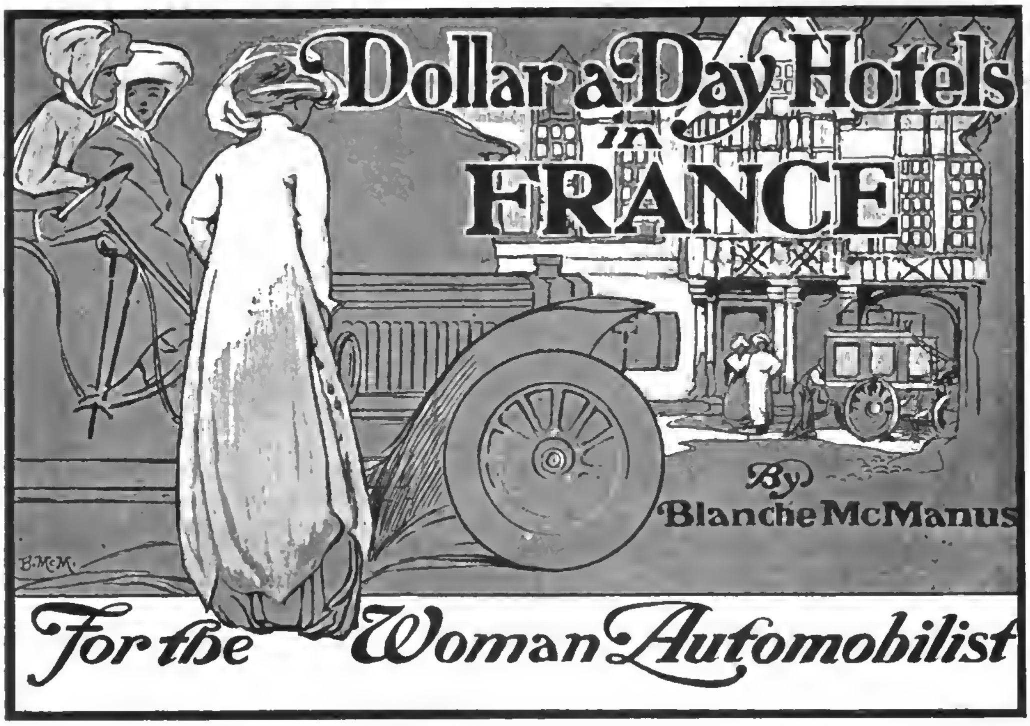
The Blue Book Company says:

"These figures show the interest which has been taken in touring in the past year, and it is estimated that they will be doubled during 1910. The amount of touring which will take place next year will be enormous. The cars being purchased have greater reliability than those of the past, and the increasing enthusiasm for country traveling will bring about, it is expected, a constant procession of cars on the country road next Summer. That the hotels and garages all over the country anticipate this is evidenced by the number of new enterprises of this character which are stretching out.

"Many of the hotels who cater to the wants of the motorist are making additions to their buildings, and many garages with up-to-date equipments are being built in nearly all the prominent cities."

The publishers of the Blue Book, in preparation for the big demand which the work will receive next year, intend to make the book the most complete road guide ever issued. A new system of indexing will be adopted, new maps will be prepared and many new routes which the Blue Book cars are now preparing will be worked up in a most interesting manner.

President Taft Boards a Stoddard-Dayton in Pueblo, Colorado



innkeeper more likeable than its patron, Thiriet. Tastes vary, of course, but all who have come to Hotel Bellevue, sooner or later come back again, as we find ourselves returning there year after year, declaring that in all France there is no place like it.

Hotel Bellevue is built on the vine-surrounded courtyard plan, as is so frequently the case with the country hotel in France. Several odd-sized buildings make up its mass, all of varying heights, with red tiled roofs, and enclosing in a casual sort of a way a little square of ground with a grand old lime tree, throwing out a grateful shade, in the center of the garden court. The cobble-paved Grande Rue of Petit Andelys runs before the door, and the Seine glides swiftly past the rear windows. Above towers a white chalk cliff crowned with the majestic ruins of Chateau Gaillard, built by the romantic yet energetic Richard Cœur de Lion more than a thousand years ago.

The hotel has aristocratic antecedents, too; the main portion was once the seigneurial manor house of a noble French family, the Beauforts, and Monsieur Charles, as we always familiarly think of the hotel's kind patron, points out with pride their arms still to be seen graven over the *porte cochère*. He shows one, too, with quite as much pride, that there is running water in the large front guest rooms with moulded ornamented ceilings, a most unusual thing to find in a country hotel in France, or, indeed, anywhere in Europe.

Hotel Bellevue is no common caravansary, dating only from the degenerate times of Louis Philippe. No, indeed, it has its own cachet and character, and so also has its owner.

M. Charles (though how we ever came to call him Charles, since his patronymic is Auguste, no one seems to remember) is representative of the best type of the French small hotelkeeper that one may expect to find in a lifetime of travel. Fair in his dealings, trustful with the stranger, content with a small turnover in business, and intensely conservative, Thiriet of the Bellevue has a personality one can but admire. He comes from Lorraine (that lost child of France), leaving his beloved *pays* as did so many others rather than remain longer in the shadow of the eagles on the German helmet.

M. Charles worships old traditions and old things, and scorns imitations with an *art nouveau* twist. Nothing gives him greater pleasure than to show his collection of "Old Masters." Are they "Old Masters"? That is the question many have often debated. Perhaps they are not; wiser men than the genial patron of the Bellevue have been deceived in such matters before now. Anyhow, it's a good guess that he has a Wouvermann and a Cuvo, unless signs fail. What matters it after all, so long as they give an air of dignity and antiquity which well becomes the long corridors of the hotel. All about the house there are pieces of old furniture and bits of rare china at which no critic can carp, and many an American with a long purse has tried to wheedle, unsuccessfully, M. Charles into parting with them for cash.

Last Spring, according to custom, we arrived

WHERE are they? What are they? How are they? we are invariably asked when we unconsciously descant on some case of the charming little artists' hotels we have known in France.

Well, they are not to be found everywhere, and not everyone who lodges beneath their spreading gables get the *prix de faveur* that is granted men and women of the palette and the brush. You must be properly presented to come within the fold, or at least show tangible credentials; the mere carrying of a paint box and a white umbrella will do this, even if you arrive in an automobile; otherwise you may pay seven or eight francs for the same fare. There are many, many of these unpretentious, but altogether lovely, haunts, but the following in Normandy, Brittany, and Provence are sufficiently wide apart and varied to suit the most catholic of tastes.

Hotel Bellevue, Les Andelys—We came first to Hotel Bellevue to stay a day; we remained three years. Those were the days when the author-chauffeur essayed to tour with a *tri-car,* that English automobile abomination, a sort of voiturette on three wheels, with one seat in front of the other, a species which fortunately never found its way to America. On the particular occasion when we fell upon Les Andelys we were proceeding by easy stages up the valley of the Seine via Caudebec and Rouen. Something was more than ordinarily wrong with this obstinate automobile in miniature, and we made our entrée into the lovely twin Andelys, pushing the wretched thing of a tricar before us.

Really we were bound for the Grand Cerf at Grand Andelys, starred by Baedeker, and two kilometers from the Seine, and only the mere accident by which Petit Andelys happened to be within a shorter pushing distance caused us to turn into the portal of the Hotel Bellevue, snuggled closely beneath the haunches of Richard Cœur de Lion's "Saucy Castle." This was the only good service that miserable "*tri-car*" ever did for us.

We have journeyed in a real automobile up and down and around France many times since then, and know intimately many pleasant resting places of all ranks within its borders, but none, in charm of situation and old-world simplicity, is the equal of Hotel Bellevue, nor have we ever come across an in Normandy from the South in apple-blossom time and turned our auto into the garden courtyard of the hotel as naturally as though we had left but yesterday. M. Charles met us all smiles, cracking the joints of his fingers, as he always did when pleased and excited. Besides M. Charles, equally beaming and gracious, was Louise, Louise who had come to the Bellevue five years ago, the very day we first entered its shadowy courtyard. Our rooms, "on the quai" overlooking the river, were always ready for us, no matter how much this desirable location might be wanted by any one else. For some days we were treated with greatest distinction, after which we fell into our old position as "one of the family" and suffered with the rest of the household when occasional attacks of "*mal à la tete*" or "*mal au dos*" ruffled our otherwise always good-natured patron.

The Hotel Bellevue of Petit Andelys is doubly delightful; besides being a very good hotel, its price is low, and lower still if you are an artist. What a cosmopolitan Summer colony we have often made there, and what discussions on art and literature and on automobiles have held forth around the long table set beneath the *tilleul* tree in the garden of a Summer's night.

Ever since we had been coming to the Bellevue we had been exercising our utmost ingenuity to induce M. Charles to add some needed modern improvements. It was not that we would in the slightest manner mitigate the hotel's charm, nor that of its genial patron, though true it is that there was sometimes a lack of proper service, and M. Charles himself would frequently let an automobilist who sought shelter late at night go away again because he would not go down and open up the *porte cochère*, and this even though there were vacant rooms on hand.

Besides land automobiles there come frequently parties of from three to a dozen or more by automobile boat down the Seine from Paris, often unannounced, and usually at an unseasonable hour. The automobile boat is seemingly a more capricious piece of mechanism than the land variety. M. Charles would stow away all as comfortably as possible, so long as they did not arrive in the middle of the night or some abominably early hour and everybody would be perfectly content.

The Hotel Bellevue's accommodations for automobiles had always been limited, and this year we succeeded in getting M. Charles to turn the stable into a garage. For years we had been agitating this question, while our own auto had suffered the indignity of being housed among the tubs in the wash room. M. Charles, in spite of the sign of the Automobile Club de France displayed on the front of the hotel, refused to put out the now sole occupant of the *remise*, the cart horse of the butcher opposite, and make room for the automobiles which, under existing conditions, had to stand on the flower beds or overflow into the narrow streets.

It was a matter of sentiment; he recalled the days when the green painted stable tucked under the courtyard gallery sheltered the relays of horses for the coach from Paris to Trouville, whose ribbons were handled by Gordon Bennett. It was as if he were purposely holding the stable in readiness for the hay motors which now came no more. This coaching craze was a wealthy man's caprice, but it was really he and no other who discovered Hotel Bellevue, perhaps twenty years ago, and thus gave its patron his start, and one has but to mention the name of the owner of one of America's greatest newspapers to open the floodgates of M. Charles' reminiscences.

It was only when Isabel and I painted a sign as beautifully as we knew how, a big red lettered "garage," a silhouetted automobile and a big red "danger spot" on a white ground, and presented it to M. Charles to hang out, that he bowed to the inevitable. It was a desperate measure, but it opened the *remise* of Hotel Bellevue to the modern usurper of the road, the automobilist.

The Hotel Bellevue has changed its aspect and its attitude mightily of late, but to those who are habitués it remains ever what it has been in the past, the most delightful and satisfactory dollar a day hotel in the Seine valley, if not in all North France. Of course you have to be one of the "elect" to fall in with M. Charles' good graces, but anyway two francs fifty for *déjeuner*, three francs for dinner and a franc and a half for a room is not dear.

Giverny: "Baudy's"—Twenty miles above Les Andelys, following the Seine towards Paris, is a little artist colony, mostly Americans, and mostly automobilists. Years ago "Baudy's" was but a little grocer's shop in the village which sold salt, matches and tobacco, all of them monopolies of the State, and some other things besides. Gaston, the younger Baudy, married a Parisian, but neither prosperity nor his wife have spoiled him. Gaston is always obliging and courteous, and has an amazing conception of the wants of his clientèle.

Giverny began its career as an art center by being a little painting place for artists who did not want landscape effects that were too exciting. Monet started it, when, to indulge his taste in gardening, as well as painting, he first made his home there years ago. But the real boom struck Giverny and Hotel Baudy with the American invasion.

How it came about no one can explain, least of all the invaders themselves, for so far as natural beauties go Giverny is one of

One Dines Much Outdoors—Hotel Bellevue's Vine-Surrounded Courtyard the tamest places in France; but this little collection of Norman farmhouses (one can hardly dignify it by the name of a village) has become one of the most Americanized spots in Europe.

The little colony is now something of a close corporation, with Hotel Baudy as a head center, for even the "residents" are more or less dependent upon Baudy's for coal for their stoves and gasoline for their automobiles. We never lived at Hotel Baudy at Giverny; it was too near Les Andelys to beguile us into leaving the Hotel Bellevue often; but we used to run over for *déjeuner* in the garden, and Giverny was just a pleasant afternoon's ride if we wanted to take a friend over to show them the house of Claude Monet, he who first made impressionist painting popular and the *vrai maître* of the art to-day.

Artists being much like sheep flock together, and now that Giverny has become a center and Baudy's has so greatly increased its accommodations the throng which descends upon the village during the Summer months is simply another inflowing wave of prosperity to the neighborhood, to "Baudy's," and to the original inhabitants and bids fair in the course of time to change the face of nature itself.

At Giverny itself the maiden from over seas who demands a whiff of the art atmosphere which surrounds the great, even if she gets no further, can look through the gateway into Monet's acres of garden, and can be sure of meeting the white-bearded painter himself driving about in his automobile, for he is an enthusiastic automobilist.

Frederic MacMonnies' house and studios are show places, too, and the slender painter-sculptor is one of the most constant figures on the tennis court. Rumor has it that Giverny is to lose this celebrity who, after a lengthy residence here, has finally decided to return forever to the land of his birth. At Giverny one can easily get five francs' worth in a day at "Baudy's," and it is still possible to get that price if you are properly credentialed, though the specially conducted travel parties for young ladies who are beginning to drop in once and again, and regard Giverny as a possible center for culture may not always know it.

Chez Julia at Pont Aven—We had slept many times beneath Julia's roof in the past and had come again to Pont Aven to see for ourselves just what had taken place in the "Ville des Moulins," as it is affectionately called by those who know it. Julia's, in times past, was the biggest nursery for art in France, and we wondered what it was like now.

It is a long pull by highroad and byroad across country from Les Andelys in Normandy to Pont Aven in Brittany, and "Julia's," as the "Hotel des Voyageurs" is always called, and we started from the Hotel Bellevue at an early hour one May morning and set out for Finistère, knowing full well that the itinerary, via Alençon—where the lace comes from—Mayenne, Vitré Ploermel, and Quimperlé, would be a delightful one.

After a singularly faultless three days we arrived at Pont Aven and entered the little town by an unprepossessing back street and drew up in the tiny place in front of what we had formerly known as "Julia's" modest establishment. We fully expected to find that "Julia's" had changed from the old days, but were hardly prepared for the overpowering many-storied edifice of brick and stone and steel beams which rose before us. The change was even more apparent when we entered and were taken up to our rooms, furnished on the department store plan, with brass bedsteads, rocking chairs, electric lights, electric bells, and bath tubs, too, on each floor. On the ground floor there was an imposing salon and a private dining room where dinners were served to order to real tourists. It is not easy to explain after all why these things should so completely spoil a place, but "Julia's" is certainly an example of how signs of progress can do harm, albeit it means profits to Mlle. Julia.

The original "Julia's" had its beginning years ago in the modest little Hotel des Voyageurs, which still stands in the shadow of the present imposing "*annexe.*" "Julia's" was then run, as it is now, by Mlle. Julia, a capable, strong, sound-headed, hard-working Breton peasant woman. Then all was simple and excellent and full of what is fondly called character. Now "Julia's" is still excellent when it comes to food and drink and a well-kept house, but simplicity has gone with the old clientèle.

In the old days there came to the little hotel a coterie of artists each year, Americans, Englishmen, and a scattering of Frenchmen, drawn there as much by the charm and comfort *and price* of the *pension*, as by the picturesque water-mills and quaintly coiffed peasant girls which offered such appealing subjects for the artist's brushes.

Julia, level-headed business woman, saw the possibilities ahead and succumbed to the pressure from without. How can she be blamed? Who of us has the courage to raise the umbrella which will ward off a golden shower? One dresses for dinner now at "Julia's." There are bridge parties in the salon, and automobiles are in each other's way in Pont Aven's small Place, and completely overrun the *remise* of the hotel at times.

Is Julia content? She has made and is making money, and making it fast. Julia is one of the self-made wealthy women of Brittany to-day, but she complains bitterly that the artists—the real artists—have left her. Prices have risen at "Julia's" to the height of the new hotel, but, it is said by those who know, that there is not one of the old crowd whom its *patronne* would not gladly welcome back at five francs a day, or less, if they would only come.

The Père Chabas—When Autumn leaves begin to turn in the North it has been our custom for many years to turn the prow of our automobile towards Martigues and the Hotel Chabas.

Martigues is one of those unspoiled places that certain people are always longing for and looking for, but never really like when they find them. In reality this class of travelers chiefly want big hotels in gay centers, and such will do well to give the Hotel Chabas at Martigues a wide berth. But for those who want to see the most beautiful corner of Old Provence, a *petit pays* with a character all its own, and would receive one of the "warmest welcomes at an inn" possible to conceive will do well to drop into Hotel Chabas, which sits at the entrance to the little village of Martigues, coming from Marseilles by road.

Provence is much more than an old name for a number of the *départements* of modern France which border the Mediterranean, but boundary lines are vague and shadowy to most travelers. It is recognized by the French as a region with its own traditions, its own language, its own customs; and with respect to these things, as with many others, one which bears little resemblance to the rest of France, while a Provençal is as unlike a Parisian as a New Yorker differs from a Terra del Fuegian.

Provençal hotels are different, too, from hotels in other parts of France, are more primitive, for instance, which adds to their interest, but not much to their comfort. And Hotel Chabas is a typical Provençal hotel, though if one will but put up with its obvious discomforts for the sake of its warm-hearted, kind Provençaux who run it, and many other things besides, they can pass some delightful weeks in Martigues, the "Provençal Venice," the painter's paradise.

Hotel Chabas may lack many things that most people want, or at least would appreciate, but it has for us a great attraction in the comfort and ampleness of our studio apartment. An American artist (one of the few who ever got to Martigues) came along one day and persuaded the Père Chabas to put in a skylight in a great room on an upper floor, and lo! the studio grew into being. It's the only forward step in the march of progress that the hotel has ever taken. In all other respects it is as it was a hundred years ago. It was built for a convent, and remained one until the Revolution forced on it a secular existence. Its long, dark corridors, off which open the small rooms, are reminiscent of conventual seclusion, and its lack of fireplaces suggests a régime of religious severity. This is one of the hotel's handicaps, for in spite of the fact that the sun shines more days in the year at Martigues than anywhere else in France, it can be cold enough in Winter by the very contrast.

One's automobile is stabled comfortably enough in the ancient chapel of the convent, now the *remise of* the hotel, which is still crowned by an empty bell-tower, and the small, wiry Provençal ponies now munch hay where the high altar once stood. What an interesting travel book an automobile could write if only it had the genius of Rudyard Kipling's machinery. "Garages I have known!" In France and elsewhere an automobile has some strange bed-fellows once and again.

Changes have come over Martigues, but it is not yet spoiled, and only automobilists with a spirit of adventure latent in their breasts, or a good bump of location, ever seek it out as they are bound from Paris to the Riviera. They keep chiefly to the great Route d'Italie and pass it by forty kilometers distant as they turn off at Aix-en-Provence leaving the road to Marseilles to the right at Orgon. These indications of the exact location of Martigues are all sufficient to the serious minded; let others who might not like it stick to the main route and make "la vitesse" to their heart's content.

The Grand Hotel Cendrillon—At the name "Riviera" one's thoughts leap at once to Nice, Monte Carlo, and the other luxurious resorts of that brilliant galaxy of Mediterranean playgrounds paralleling the coast from Marseilles to the frontier.

How many of the world of pleasure seekers who for the Winter months annually flock to the famous Cote d'Azur—as the Riviera is better known to the French—have an acquaintance with, or have ever heard of, Cassis?

Cassis is simply an obscure, tiny port, three kilometers from the railway, and as far removed from the glitter and gaiety of Cannes, Nice, and Monte Carlo as its small, enigmatic Hotel Cendrillon is unlike the palm-shaded, palace hotels of "la Cote."

Hotel Cendrillon owns to a dozen rooms, and is but an outgrowth of a *maison bourgeoise*, recently come into being as a hotel. It has, too, a strip of walled garden, planted with a couple of stunted palms and overhung with two towering pines. On top of the garden wall is a "terrace," or belvidere, overlooking the busy port, with the open sea beyond, and the unkempt Place or Square at its feet.

Cassis' nineteen hundred inhabitants divide their time between fishing and hauling crushed stone and cement from the mountains roundabout down to the port, there to be loaded on to the picturesque Mediterranean craft of all shapes and sizes which crowd the *darse*.

The only real excitement and hilarity for Cassis, its inhabitants in general, and those who live under the roof of the Hotel Cendrillon in particular, is on Sunday when an excursion steamer ties up to the quay, having brought out a crowd of Marseillais to eat *bouilla baisse* and play bowles. This, or an automobilist, strayed by accident from the great "Route National," are the only real dissipations of Cassis, so far as mingling with the outside world goes.

Hotel Cendrillon may be modest and retiring enough, but its proprietors are not. They think their hotel second to none on earth. The Ferauds are a typical Provençal couple, good-natured, warm-hearted, boisterous, and romancers, vivid and unblushing, all this overlaid with a childlike simplicity. Neither has ever been twenty miles away from their own *petit pays*. They had risen from being proprietors of a small wayside house of call, a halting place for the drivers of the heavily-laden *charettes* on their climb up out of Marseilles over the Estaque Mountains, to what they fondly imagined was a resort hotel. The transition has left them a bit dizzy and uncertain. At the time we happened on Hotel Cendrillon they had just prefixed the word "Grand" to their hotel sign, and had printed Cassis-Sur-Mer on their letter heads. These little things attended to, they sat down to wait for the golden stream of prosperity to roll their way. We broke rudely into this golden dream when we coasted down the mountainside into Cassis one Midsummer's day and drew up in front of Hotel Cendrillon.

The Ferauds had never come into contact with vagabond travelers who journeyed by automobile; they were expecting a gilt-edged clientèle only, and had arranged their prices to suit (as they fondly believed) this exclusive trade with which their hotel was to be inundated. Our modest automobile deceived them for the moment into thinking that the vanguard had arrived.

But our author-chauffeur and "business manager," without leaving his seat behind the wheel, firmly, but dispassionately, argued the matter out with the excited little couple who were dancing around us in a perfectly irresponsible manner. Five francs a day was our limit, and the price usually given to people of our proclivities for a stay throughout the country.

The mere fact that we arrived as automobilists through necessity, not wealth, and not as artists with white umbrellas was against us. Finally, upon convincing the couple that we knew our French well, and that there were many places even more attractive (with a contemptuous wave of the hand at the "Grand" Hotel Cendrillon) where, at this price we would be welcomed, literally, with open arms, the chauffeur prepared to move on.

How far the Ferauds believed all this is doubtful, but the prospect of a party of four driving away under their eyes (we were all still in the automobile) shook their nerve. They capitulated. And this is the true story of how the Grand Hotel Cendrillon fell from its high estate and became a dollar-a-day hotel. Those who come after us and pay more than that cannot possibly get more value. That is the difficulty with the resources of the hotel in the small French town. It is not possible to cater for you differently, whether the price you pay be the four or five a day charged a *pensionaire* or the ten or a dozen put on because you are an automobilist. With all its good points, and there are some, the Grand Hotel Cendrillon at Cassis-Sur-Mer is, frankly, not worth any more than five francs a day, whether you arive on foot or in an automobile.

We did not fare so badly at Hotel Cendrillon after all. But what virgin soil in which to plant new ideas! So we thought, and tried it, though we never got further than teaching the proprietor how to make toast—it was he who made our "little breakfast." This, and cleaning the knives (a job to which he could sit down) formed the bulk of his work. On Sunday, in his best clothes, he stood on the lookout for automobiles.

The mere sight of an automobile threw the Ferauds into a delirium. At the first sound of a horn way up the mountain Madame would rush from her kitchen to the window in the garden wall which commanded the little place, abandoning her cooking to any sort of charred fate that it might befall. Out of this window she hung, like a fat spider in its web, and with sweet smiles and words would try to entice the automobilist to enter, who, to speak truly, is usually as gullible as the traditional fly. Not all of us are, though, and no one really likes to be thought such, so these words of warning.

It was Madame who did the cooking. Also Madame was the intellectual head of the house. She was acquainted wtih Dumas' novels, and all the time we knew her she had in hand a "yellow-back," which she was always offering to lend us, entitled "Mignonette." It was one of those flimsy French things.

Madame Feraud was a poet, too. She could turn out a poem while you waited, written on a corner of the kitchen table in the Provençal patois. Meals were good enough, but problematic. There were days when we rolled in abundance, and there were days when we went out and bought things and cooked them ourselves. Those were the days when Madame conceived a new poem or "Mignonette" blocked the ordinary course of household affairs.

Still, both Monsieur and Madame felt much hurt when we left to take up our Winter quarters at Martigues, where we had a little *pied de terre* always awaiting us. Madame wept at parting, and Monsieur sped us on our way with a gift of half a dozen bottles of the famous white wine of Cassis.

Let us hope that nobody will be so cruel as to send the proprietors of the Hotel Cendrillon a translation of this, as has been done by officious persons with our written remarks on things French in times past, thereby causing coolnesses between us and some of our friends. We hope again to listen to another of Madame's poems, while slow-footed Felicie spreads the table in the shady garden of Hotel Cendrillon, before the Cassidiennes wake up to the knowledge that they are a part of the "real Riviera" and begin to plant palm trees on the quay.

One-Car Garage of Squared Field Stone, Which Appears Well and Is Very Well Arranged Inside

SO MUCH has been said about concrete and cement in the previous chapters of the story of the private garage that a note of warning must here be sounded. It is not necessary to use either in order to have a well-built, well-arranged garage; in fact, many of the very best garages are of stone, brick, or wood in combination with either of them. This is, of course, not said to deprecate cement, but simply to present the other side of the question, namely, the stone and brick side.

Even in the stone and brick house, there will be much cement used for floors, wash racks, foundations, and otherwise, but in the main, houses built chiefly of brick and stone, and having that external appearance, will be described.

Thus, the illustration at the head of this article shows a good example of squared field-stone construction. This is not laid up in courses, but as broken ashlar, the mortar or cement joining the individual stones being "pointed out" for the sake of appearances. In size, the whole building measures about 17 feet wide by 27 feet long. Of the total length, about one-third is given up to rooms for the chauffeur.

Adequate Provision for Driver Important—This matter of providing quarters for the driver is one that has a considerable influence upon the other matter of employment of chaffeurs. This latter, always a troublesome point, is greatly simplified and the chances of getting a first-class man and keeping him much improved, if proper provision is made for housing him and his family. The family need not always be counted upon, as in the present case, for instance, the quarters provided are large enough for but one. This, of course, presupposes an unmarried man as chaffeur.

The quarters provided in this case consist of but two rooms, if the bathroom be not counted. These are a bedroom and a small living-room. When the size given over to the rooms is considered, 8 feet x 16 feet inside, it is apparent that the rooms are small. However, this may be offset by the fact that a single man would be likely to use them very little. For the bedroom, as an example, only room for the bed would be necessary, namely, 7 feet by 5 feet.

Similarly, with other rooms, the need for space is small.

More liberal is the space allotted to the one car owned, this measuring 16 feet wide by 18 feet long, inside. These are the gross dimensions, as the door subtracts something at the front, while at the two sides are placed the workbench and cupboards. The latter are unusually complete and well-suited to the purpose, being built with doors for the upper part and drawers for the lower half. The doors open for access to a series of shelves, about five in number, and perhaps 3 feet long, two sets being located side by side.

These shelves begin about 3 feet 6 inches off of the ground and extend upward to about 8 feet. Below them the cabinet, if it might be called that, is widened out from 18 inches to about 2 feet in depth. In this wide part are located the drawers, three high, and two wide, as in the case of the shelves. This outfit provides more space than could possibly be used for the repair parts and tools of a single car, so that there is opportunity for "a place for everything and everything in its place," to paraphrase an old saying.

On the near side, the workbench provides plenty of room for ordinary repair work, being about 8 feet long by 2 feet wide. A pair of vises, one for large and one for small work, give ample provision for the driver to show his mechanical ability, while the several drawers below the bench provide space for the tools he would use. A skylight above of an area equal to fully one-fourth of the floor space, lights up the whole interior, assisted by the window shown and a duplicate on the other side, as well as the open front doors when the weather allows.

Another One-Car Garage of Glazed Face Brick

Heating System Very Important—Of great importance usually, when the chauffeur and his family or the chauffeur alone is housed in the same building, the heating system assumes a position of greatly increased importance. In fact it becomes *the* problem. In this case, a happy solution was effected. The garage is close to the rear of the house, unusually close. The rear in this case is the windy side of the place, and so, is cared for more than is usual. The heating means is steam. To heat the nearby garage was then a simple problem, a mere matter of connecting pipes.

It was effected as follows: The steam pipes for the rear of the dwelling were continued (underground) into the center of the side of the garage nearest to the house. Then a large radiator was placed in the center of that side and connected to the steam supply. Its position is such that it is against the wall of the driver's bedroom, thus furnishing plenty of heat for that. In actual location, however, it is in the automobile room, so that there is plenty of heat to prevent the water in the circulating system from freezing, no matter how low the temperature gets.

Aside from those described, this garage shows no other unusual features of interest. The oil and gasoline tanks are both outside of the building, buried under the ground. The top of a barrel of oil, waiting to be put into the underground tank, may be seen in the foreground, just above the stone wall.

Glazed-Face Bricks Give a Good Appearance—In the second garage shown on the first page, cement, studded with small round field stones, is used for the portal and foundations, or at least that portion of the foundation which is above ground. The rest of the house is constructed of brick with a glazed face. As the picture brings out, this gives the whole structure a very clean, neat appearance. Around the lower part of the outside is carried a water table of concrete slabs, which, dividing the pebbled surface from the smooth finish, gives the house an improved, not to say, finished appearance.

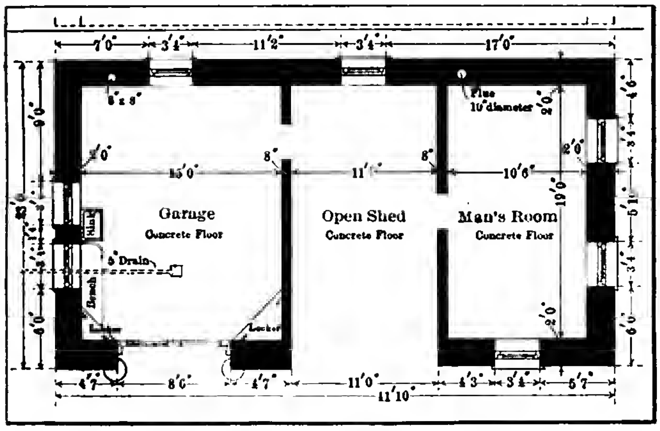
At the front, the portal which serves but for a door compartment adds very materially to the looks, as do also the overhanging wooden eaves. Speaking of the roof, the combination of three different shapes—the peaked, the square, and the mansard—adds very much to the *ensemble*.

This car space is nearly square, if anything, a little longer than wide. In the center, the washstand is placed, so that the car is driven right onto it, in coming in. In the picture the car is shown on the wash stand. The back door allows driving right through, although the interior is large enough so that the car may be turned to come out of the same door by which it entered.

At the right, nearly hidden behind the bush, is the door by which the owner may enter, this being near enough to the main or car doors to allow of entering by the small door and opening the car doors from the inside without much time wasted in either time or distance traveled.

Although none are shown on the side picture, the number of windows on the other sides is ample, and the interior lighting is very good. This garage, just recently completed by the owner, A. B. Harmon, is located at Frankfort, Mich. The upper part, above the automobile room, is finished off and furnishes plenty of room, either for storage of tops, robes, etc., or for chaffeur's quarters, should it be desirable to use it in that manner. The chimney, which may be seen very faintly to the left and above the roof, provides means for heating.

Field Stone Construction Popular—Elsewhere on this page is to be seen a slightly larger garage built of field stone. This form of construction is gaining favor every day, particularly



Plan of Unique One-Car Garage in Stone

This Garage, Large Enough for Six Cars, Houses but Two

for cases like this. The place is located in the country, so to speak, being about 20 miles above New York City, and really far from any other city. The house occupies the top of a high knoll, overlooking the Hudson River, of which a magnificent view is obtained. The knoll is of rock, and before any building can be done on the premises blasting must be resorted to in excavating for foundations. The result is that plenty of stone is handy, the railroad station is far away, so that it is no wonder that the stone is used for the walls instead of cement.

In form, the building is slightly deeper than wide, the depth being 30 feet against a width of but 22 feet. The picture is taken of the width, and gives scant idea of the much greater depth. Like all of the other buildings on the estate, this is of field stone laid up as broken ashlar, with shingle roof and concrete floor. Probably the most apparent feature shown in the picture is the front door arrangement.

This consists of a pair of doors, hinged in two places. This allows of folding up each door into a very narrow compact unit, one-third the width of the door when full open. But one of each pair of hinges opens toward the inside of the structure, so that latches to prevent it being pushed in at times when the owner is not around are necessary at but those two points. In the main, the door folds to the outside, and when closed normally rests against a metal strip which projects above the floor.

Within there is a large clear central portion, which the car occupies. At the sides of this are placed, respectively, the workbench on the left and the tools on the right. The latter consist of a hand drill press, mounted upon a post let into the wall, an anvil and fire, while the gasoline pump and washstand are located on this same side. The last named is a small affair intended for the owner's personal use, and should not be confused with the wash rack for the car, which is in the middle of the cement floor. It is located close to the door, so as to be convenient on leaving. Thus, having completed a dirty job on the car, everything is cleaned up, and just as the owner is about to leave, the last thing he wants to do is to wash up.

Some Slight Provision for Heating—Since the automobile should not be left without any heat in the winter, slight provision is made by the fireplace at the far end. This was built in at the time the building was constructed, and is connected to a very large, wide chimney, the top of which may just be seen in the picture. The latter would provide plenty of draft, but it would seem as if an open fire of this sort would be dangerous where much oil, gasoline and oily waste were unavoidably present.

Including the windows in the door, six in number, the light provision is ample, as there are ten other windows, three on each side and four at the far end. The size is such as to require considerable light; in fact, in spite of the numerous windows the interior appears very dark. Another feature of this garage worth speaking of is the maneuvering space left in front of the building. This has a tapering shape, from the very narrow neck, where the car must enter, to the very wide part just to the left where the car may be seen. Its shape and size are

Garage Which Was Stretched from One to Two Cars' Capacity

such that the longest car could make the full turn in one change of direction. The other cut on the previous page shows the plan of a stone garage of some merit. It is not large, but more space is provided than the one car would seem to call for. The first thing to be noticed is the open center portion, located midway between the automobile room and the driver's room. The latter is like the one previously described, somewhat small, and evidenty intended for a single man.

Inside it measures 10 feet 6 inches by 19 feet, slightly larger than the other one. The entrance in the middle of the side would give the impression that it, also, was divided into two parts, a living-room and a sleeping-room. The size and arrangement, too, would seem to carry out this idea, two being placed in the front living-room, where light was more desirable, and the single window in the bedroom, where light is not so needful.

In the automobile room little of novelty is found, the usual arrangement being followed. This gives the double doors, the drain for washing purposes close up to the doors, the workbench fairly close to the drain, so that work can be done on the car when being washed. Close to the workbench is the sink, where the driver could wash up, this also being close enough to the car position to be handy for filling the radiator.

Small Frame Building for Two Cars Unique—At first sight the unique features of the small frame garage for two cars, shown at the top of this page, are not apparent. In fact, it looks just as one would expect any well-designed frame garage of that capacity to look. The shape of the roof gives a slight clue to the peculiarity. This lies in the fact that this garage was originally built for but one car and was enlarged to accommodate two by cutting the building in two along the center line, widening out to two-car size by moving one-half over, and then filling in the missing portions. The two changes in direction of the slope of the roof indicate where the parting was made, the left-hand part being the older, or first-built, part, are also the right-hand wall and the first part of the right-hand roof.

The mansard part of the roof, the center portion, was added, the door at the left was duplicated, and the front and back walls sided up to match the other parts. One window at each side and one at the rear afforded scant light for the enlarged building, so when the changes were being made another window was added in the back and a skylight on each side of the roof. The garage is short and gives little room behind the car, or in front of it, for that matter. This determines the position of the car in the garage with some accuracy, and the skylights were located so as to afford overhead light on the engine of the car.

Another feature of this garage is, like the first, unique and also invisible in this picture. To understand it at its full worth the statement must be made that the whole building, first for one car, and later, as shown, for two cars, was built with the utmost economy. The floor is of wood, spruce being used except directly under the right-hand portion, where the Cadillac car shown is kept. There the floor is of concrete. This concrete floor is very small, exceeding the wheelbase of the car in length by but a few inches, and the tread in width by a similar amount. Like the various other parts of the building previously described, this was dictated by economy, the concrete floor being too expensive to use for the whole width and length, so all of its advantages were gained without its disadvantages.

Aside from the economy of space and money, the interior shows up with marked excellence; the light is good; the arrangement is even better, there is a place for everything, water, oil, and gasoline are provided in the proper places; tool equipment is complete and well selected, etc. The inside size is 20 feet wide by 18 feet deep. In this space the two cars, a four-cylinder Cadillac and a six-cylinder Ford, share equally, each having 10 feet in width. In depth, however, the workbenches, clothes closets, and other things congregated at the back reduce the available depth to about 14 feet. There is a source of water supply at each outer corner, so that each owner may use water at the same time without bothering the other. The gasoline tank is buried outside in a convenient place in front, and holds three barrels.

Three-Car Frame Garage—When it comes to a multiplicity of cars of high power, which usually spells long wheelbase, the garage requirements go up very fast; that is, the size must be unusual, particularly when the land provided is such as to call for a narrow building.

This is shown in the garage at the bottom of this page, which houses three big Thomas cars, two of them "sixes." The view was not taken to bring out the length, but, on the contrary, to reduce the apparent length as much as possible. The actual inside measurements were 24 feet wide by 60 feet long.

This great length was lighted by means of seven large windows on each side, as well as three equally large ones across the back, and whatever light entered at the front end from the one window there or the open door. The wash rack was at the front, just inside of the door, but in fair weather the cars were washed outside on the big cement platform provided as a runway. This measured 25 feet by 25 feet, so that it would be easily accommodate several cars at once.

Gasoline was furnished by a 500-gallon Bowser tank located at the left side of the building near the front road. The interior was heated by a large stove located just behind the stairs and toilet, in about the center of the length of the first floor. As the area to be heated was great, and as this one stove heated the living-rooms upstairs also, it was very large in size.

At the rear end extending clear across the building was a large workbench fitted up in the customary manner. The building, although frame, is made as nearly fireproof as possible by the inside sheeting, which is of ornamental sheet steel, as is also the ceiling of the lower floor. The floor is of concrete. The living-rooms above are unusually complete, comprising six large-sized and very conveniently arranged rooms for the chauffeur.

(To be continued.)

Automobile Vibration and its Physiologic Effects

By André Gonthier

CONSIDERED from the point of view of means of locomotion, the present age has been decisive. Important inventions have revolutionized that branch of human knowledge and have contributed powerfully toward the advancement of the world in the process of evolution that is being carried out. We live in the century of speed. In the present organization, a simple stoppage—a mere falling off in the means of communication—brings in its train great disruption. Present relations and exchanges between individuals and populations are so intense and so necessary that their continued maintenance is a matter of life or death.

Where are the peaceful trips of other days? The berlins of long ago, the diligences, and the good old times when no one was in a hurry? What a veritable revolution has been brought about in means of transport! And when their importance is considered, the character they have taken, the changes, transformations in habit which their use imposes, even to the extent of making necessary a new method of living to a constantly growing number of people, it will be evident that questions of hygiene are also involved. Swift steamers, railways, submarines, automobiles, dirigibles and aeroplanes are all means of locomotion imposing new conditions of existence, involving special accidents and bringing in their train a new pathology which is becoming more and more important. If automobile travel be considered, it will be seen that the organism of those devoted to it is subjected to multiple influences. The speed of the car, the blast of air striking the body, the cold, the dust, the prolonged immobility, the gas from the motor, and the concentration necessary are some of the factors capable of producing an entire gamut of physiological and psychological effects, which may even attain to morbidity.

The skin, certain organs of sense, the respiratory apparatus, the circulation, the oxidation of the blood, the nervous system and digestive organs are all more or less influenced. If these organs be normal and the causes in question act progressively, the individual will become inured, and, by the habit of resistance to exterior agencies, the organism will acquire a particular power of endurance in addition to that of the normal state. If certain organs be already diseased, they will also react, but in a manner aggravated or lessened by their defects.

Medicine and the Automobile—The relations which unite automobiling with medicine, while not established in a precise manner, exist none the less, since here is a means of locomotion becoming more popular from day to day, which bears upon important questions of hygiene, which may be the cause of pathologic affections, and also, it is true, be a therapeutic means —a valuable aid to the physician. It has already been noted that vibration is one of the factors by which the automobile acts on the system. Vibration, which in the automobile is regarded only as a disagreeable inconvenience to be remedied to the greatest extent possible, is also a therapeutic aid, resorted to in various cases, such as gynecology, nervous affections and the like. The patient is subjected to general or local vibration, applied either manually, or by means of special apparatus, mechanically operated.

Are the physiologic effects produced by the vibrations of the automobile comparable to those which it is sought to obtain therapeutically? What are the relations of the analogy, what resemblance can there be between the vibrations applied to the patient and those to which the chauffeur is subjected? What conclusions can be drawn therefrom? This is what we have attempted to study out.

In making a research of vibratory medicine, curious facts have been brought to light, demonstrating that for a long time past, medicine has occupied itself with a study of the effects of locomotion. If vibratory medicine be of rather recent origin in its scientific application, massage, of which it is a variation, has been known and employed since the most remote times. The medical literature of the Chinese and Hindoos show that these people had a thorough knowledge of massage. In the Graeco-Roman age, instruments had been perfected and mechanical vibration, which now interests us, was employed.

Astruc, the famous professor of the Faculty of Medicine of Montpelier, in an article appearing in *Le Mercure de France,* in April, 1735, enumerates the experiments made with this method of medication in the Greek and Latin epochs. According to him, Ovibase, Hippocrates, Coelius, Aurelian, and later, Bernard de Gordon, had all shown the benefits to be obtained from this practise. Since the beginning of the eighteenth century, works on mechano-therapeuty have become more numerous. In 1711, Hoffman, in Germany, prescribed gymnastics for hypochondria, phthisis and other ailments. In France, Chirac, the physician of Louis XV, recommended trips in a poste chaise for neurasthenia. He remarks that hypochondriacs are much benefited by riding over the block pavements of those days, of which, unfortunately, only too many evidences remain.

The success due to the somewhat special therapeutic treatment imposed by the romantic poste chaise of our ancestors inspired the Abbé de Sainte Pierre, the celebrated Utopian and author of the "Project for Universal Peace," to construct a sort of rocking chair of which the occupant was subjected to a shaking analagous to that experienced in the poste chaise, and from which, according to him, similar benefits were to be obtained. In *Le Mercure de France,* of 1734, appeared an announcement of the Abbé, unveiling his invention. The claims made are so interesting and naïve as to warrant a detailed citation.

"The Poste Rocking Chair"—"Machine for curing and removing maladies arising from an excess of nourishment, oversedentary life and lack of perspiration. M. Chirac and other skilled physicians have observed that the movement to which the body is subjected in a poste chaise, rolling rapidly over the pavement for several days, may be regarded as an excellent remedy for many of the evils attributed to melancholy, vapors, bile, etc."

He goes on to explaint in his own manner, in the physiological ideas of that day, which to us appear vague and ridiculous, how the shaking of the rocking chair would act in all classes of maladies—somewhat *a la patent* medicine panacea of our own time.

"The majority of these evils are caused by obstructions of the glands and other parts of the viscera, and these obstructions are found most frequently in those whose blood has become thickened or poverished by lack of air, which gives animation and increases the elasticity of the blood? Obstructions in the small canals of the glands are dissipated simply by the shaking and the rapid trembling of the entire body caused by the poste chaise, while, on the other hand, this sharp and continued shaking compeles stronger and more frequent respiration, thus passing more air through the blood. These effects of the obstructions happen most frequently to those who overeat and who

* Translation from the French of "Omnia," by Charles B. Hayward.

take less exercise than is necessary for the blood, of which there are a great many, particularly in the cities."

Have we not here the advice of hygienic exercise, which the modern practitioner does not disavow?

"But as the poste chaise remedy is costly and above all, embarrassing, I have invented a substitute in the shape of a rocking chair affixed to a frame which subjects it to strong and lively shaking."

Wealthy and sedentary people who are particularly subject to obstructions and lack of perspiration, may have such a machine, or trembler, at home, while others may be treated at apothecarics and by surgeons. So was launched *Le Tremoussoir*, and it raised a great furore in its time. Voltaire, writing from Champs, to the Comte D'Argental, September 14, 1744, says "I departed for Champs, instead of dining. Placed myself in the *tremoussoir* of the Abbé Sainte Pierre and here I am, a little better, etc." But in spite of its success and its illustrious clients, the novel rocking chair was soon lost in oblivion, like so many other inventions. The fact to be drawn from it was that the idea for that original device was taken from the poste chaise. It will also be seen that later, means of locomotion were responsible for the famous trembling chair of Charcot. The experiments of Zander and Nycander, both of whom invented special vibratory devices may be rapidly passed over, as well as many more of comparatively recent origin, a recital of which would form quite a lengthy chapter—more on medicine than automobiling. The prinicipal results of vibratory treatment are said to be an augmentation of the secretions, particularly of the intestinal tract, quieting of the nervous system, and the facilitation of digestion.

The Automobile Produces Similar Results—The use of the automobile and certain other forms of transportation, in which the vibration is violent and continually produces analagous results, and it seems that the physiological action of the vibrations affords an occasion to explain certain of the advantages and disadvantages of automobiling in this connection.

In a paper read before the Academy of Science, Mouneyrat has shown that in persons devoted to automobiling, there is an increase in the rate of formation of hemoglobin, as well as in the number of cells in the blood, which is explained by the action of the greater amount of air inhaled and its oxidation of the tissues. Is this not a close approach to the experiments of Colombo, who demonstrated the secretory effects of vibration? Dr. Legendre has also shown that the automobile, by reason of its vibration, affords a remedy for several forms of congestion affecting various organs. But it is hardly necessary to drag out further the catalogue of benefits or ills. It has been shown that medicine must contend with the new form of locomotion. On the railway, as on the automobile, the simple shaking, to which one is loth to attach any importance, may in certain cases, and according to the manner in which the subject reacts, mark the starting point of certain pathologic affections. On the contrary, it may also be a therapeutic aid, of which our forefathers long since took advantage.

FRANKLIN TRUCK UPKEEP REDUCED BY PNEUMATICS

SYRACUSE, N. Y., Dec. 6—An innovation in the construction of motor vehicles is the use of pneumatic tires on the tracks built by the H. H. Franklin Manufacturing Company of Syracuse. Though an innovation, this has been tested long enough so that the company is able to announce that their use results in a very low cost of up-keep. The company also states that to the fact that in their construction unnecessary weight is eliminated, is due the possibility of successful use of pneumatic tires on the wheels of the Franklin trucks.

In discussing the results secured and the use of pneumatic tires for trucks, the following statement is made by W. F. Kneip, engineer of the commercial car department at the Franklin automobile factory:

In the operation and manufacture of motor trucks the great question is the cost of maintenance and up-keep. This subject is of greater importance than reliability; indeed, reliability is actually involved in it. For example, it would be possible for us to conceive of operating a motor truck which was absolutely reliable but which, at the same time, cost an excessive amount to maintain. Of course, in spite of its reliability, its operation would have to be discontinued as it could not compete with others which could do the work more cheaply.

We will confine this discussion to trucks of 3,000 pounds' capacity and under. For such trucks or delivery wagons to show increased earnings over horse transportation their speed must be much greater. In delivery service such a truck must displace from two to three horse-drawn wagons.

In the past designers acted upon the assumption that reliability was the real key to success. With this in mind they pounced on our long-suffering and overworked friend, the pneumatic tire, and threw him out, bag and baggage. The idea was that a half hour lost now and then, due to a puncture, constituted an insurmountable barrier to the use of pneumatics. So far, we will all admit that, other things being equal, the puncture-proof tire is the best to use. But it was soon found that in order to make a satisfactory showing against horses the trucks would have to run at an excessively high speed when equipped with solid tires.

The result was that the trucks began to come apart quite rapidly, and spent considerable of their time in the repair shop. This interfered with reliability, and, in addition, greatly raised the sum of the items of repairs and tire cost. This was not all, as it was found that these high speeds had a tendency to loosen tires so that they would come off on the road. To apply one of these tires generally necessitated the removal of the wheel and the use of a huge, clumsy mechanism which took a man and a helper to operate. Thus when a tire came off on the road it was a case of either coming home slowly on the rim or waiting for a new wheel. These things interfered quite decidedly with reliability, besides costing money. The position of the operator of a single truck in a small town where there was no tire-applying machine was particularly unenviable.

To overcome this tires were finally developed that would stay on till worn off. This last kind was worse than the first, because the operator, in order to save money on tires, would let the tire wear down until it had practically no cushioning effect. His expense for repairs would be two-fold.

In the meantime, makers of pleasure cars were studying the pneumatic tire problem. It was found that there was a relation between size of tire used, weight carried and speed at which it was carried. Given a certain weight and a certain speed, larger tires would lower the tire cost per mile, at the same time assuring greater reliability from the tire point of view by eliminating the danger of blow-outs and minimizing the danger of puncture.

In a sense the problem is analogous to retail and wholesale buying, for when tires are bought it is simply a case of buying so many miles. When larger tires are bought larger packages of miles are purchased, and the rate is cheaper. The only objection to this arrangement is that it makes the first cost look high. That is one reason why so many so-called cheap cars are unsatisfactory to their purchasers. By the use of large tires, however, we have eliminated lost tires, the wasted time installing new tires and most of the lost time and money spent in repairing the mechanism. Therefore, the reliability is actually increased about one hundred per cent., while the sum of tire cost per mile, plus repairs to mechanism, is reduced.

At the same time, by increasing the safe available speed, the capacity of the truck per day has been increased about fifty per cent., and all this at the expense of an occasional puncture which can be easily remedied by the cheapest sort of help in a half hour, at most. We must not lose sight of the fact that cutting down the cost of repairs on mechanism also insures a far lower depreciation charge, so that, summing up the question of the use of pneumatics in place of solids, we find that with them:

1. Tire cost per mile is about the same or a little greater.
2. Earning capacity is increased about fifty per cent.
3. Depreciation is decreased about fifty per cent.
4. Repairs to mechanism decreased about fifty per cent.
5. Reliability, or total number of hours worked out of total number of chances, is increased wonderfully.

In fact, the use of pneumatics confines the troubles of the boss of the repair shop to minor adjustments and to the repair of punctured inner tubes.

ENGLISH DOUBLE-IGNITION SYSTEM OF UNQUESTIONED MERIT

NO longer is it necessary to apologize for the use of a double-ignition system, or to make excuses for the inclusion of a magneto, the necessity for the battery-coil-timer system having been granted some years ago. Far from it, in fact, the need for the magneto may be said to be more generally granted to-day than is the necessity for the other or alternate system.

With the growth of the magneto system, however, and the popular demand for it, has come about the almost universal fitting of both systems on the same car, the manufacturer being unwilling to take any chances, putting on both, and usually as two separate and distinct groups, each complete in itself and well able to ignite the engine satisfactorily for a prolonged period of running.

This, to look at it in a critical way, means not alone the parts of the two systems, but their placing and sufficient space to accommodate them in a workmanlike and accessible manner, to say nothing of the driving means. Since both must be driven positively, the latter requirement means a gear drive. In many engines the gear drive of two separate ignition mechanisms, coupled with the other requirement for a workmanlike and accessible manner of placing them, has resulted in an unsolved problem.

The meaning of this is that the problem, having been found too difficult for solution, has been dodged, and the result is a loss of some of the desirable quantities. Either one or both systems becomes inaccessible, or are located far apart, so that the engine is covered with wires.

New System Eliminates All Faults—With a new and decidedly different system, just brought out in England, all this is avoided. Not only is accessibility promoted, simplicity evolved, length and cost of wiring reduced materially, but by combining the two systems, or, at least, the parts of greatest importance, into one unit, while at the same time retaining the individuality of both, the desirability of having both is increased 100 per cent.

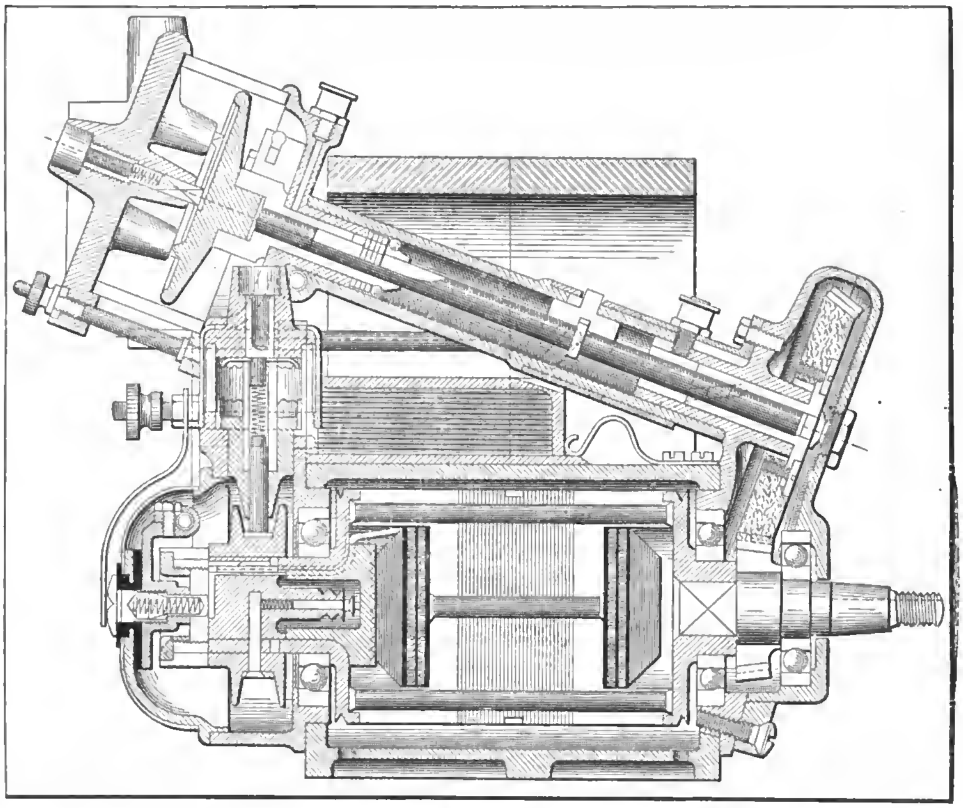
Hall-E. I. C. Double Ignition is the name given to it by the makers, the Electric Ignition Company, Ltd., Sampson road North, Sparkbrook, Birmingham, England. It consists of a magneto constructed with a distributor for the low-tension current as an integral part. Not only is this made in this manner, but it is made in two different ways, to allow an opportunity for choice on the part of the car designer. The two, both illustrated on this page and the next, differ in having the secondary distributor placed either inclined or vertical.

Inclined types lend themselves better to the placing of the magneto-timer at the rear end of the engine, close up to the dashboard, yet possessing a maximum of accessibility. The vertical type, on the other hand, while available for use anywhere, lends itself to the forward location in a better manner.

Two Contact Breakers, Two Distributors—As exemplifying the pains taken to have this system contain only those points which are good, and more—all that being good are necessary—may be noted the use of individual contact breakers and separate distributors for each system. That is to say, the high-tension magneto system has its own contact breaker, located at the front end of the driving shaft and readily removable by simply turning the spring aside. Strictly aside from this point of accessibility, absolutely without tools other than the hands, is that the magneto contact breaker works ahead of the coil which boosts the current, thus being strictly a low-tension current device.

Another distinct, yet exclusive, feature in relation to contact breakers is that the low-tension contact breaker for the battery-coil-timer system is exactly the same in all details, being interchangeable one for the other, either wholly or in part. The details of the one, then, will also be the details of the other, so it will suffice to describe either.

In appearance this is not entirely unlike the well-known La Coste timer, although there are some minor differences. The curved arm carrying the roller is used, but the spring to hold the roller in contact with the actuating cam differs. The latter is a flat spring instead of a coil, and is attached to a link which pivots on the lower end of the roller arm, rather than the arm itself.



Section Through Inclined Type Hall Magneto, Showing Ball Bearing Shaft and Distributor

The cam is regular in outline, a perfect circle, with four circular notches cut out of its periphery, equidistantly spaced. The roller rides on the inner surface of the notches normally, the rise to the outer surface making the break at the contact points. The latter are of platinum. A large adjustment is provided, with a locking screw to hold it. For the two differing uses, however, the makers recommend differing adjustments of the maximum distances apart as controlled by the adjustment. Thus, for the magneto 1-2 mm gives the best results, while for the battery system 1 mm is advisable. Expressed in English units, these distances are, respectively, .019 in. and .039 in., or a little more than 1-64 in. and 1-32 in.

Marked Difference in Unsupported Armature Length—As the two sectional drawings show, the construction follows standard practice in the main. Thus the armature is of the H slot type, the windings being concentrated in the interior of the slot. This rotates on ball bearings composed of 1-4-in. balls. The whole armature is very short and stubby, the distance between

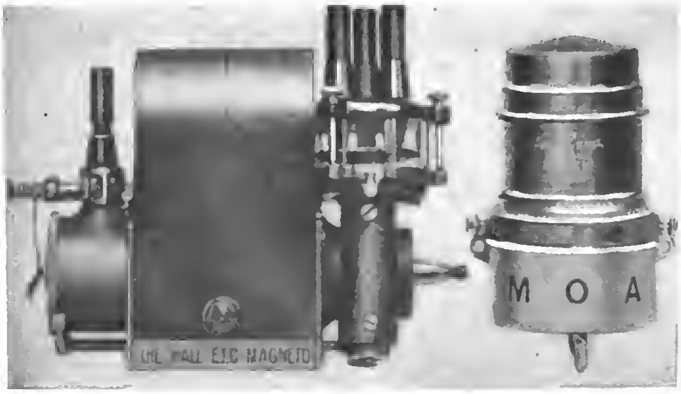


Illustration of Magneto and Special Combined Switch and Coil

the two bearings being much less than in the ordinary case. This is done by shortening the space given to the armature proper, although without any sacrifice of wires. Additional length is gained by the placing of the gear outside of the bearings, an extra bearing being provided beyond that, so that the gear driving strains are taken up by it. More than this, the high-tension collector ring—usually located close to the armature—is located just as close in actual distance from the end of the armature wiring, but actually beyond the bearing. This totals to a reduction of the usual center to center bearing distance of 6 1-2 in. down to an even 4 in. Not only is this a reduction of nearly 40 per cent., but in its bearing on the stiffness, resistance to springing and consequent rubbing against the pole pieces to cause wear, it is an improvement of more value even than that.

Accessibility is carried forward in the construction and placing of the condenser. This is made rectangular in shape, with the connection projecting on the left side as a small circular bar. With the contact breaker and safety spark gap off, the condenser may be lifted out bodily without touching anything else, not even disconnecting anything. With the two parts mentioned in place, however, it is necessary to turn the condenser up on edge, the space within the magneto being sufficient to allow this. It is then lifted out as before, without disconnecting anything.

Safety Spark Gap Useful at All Times—The high-tension collector ring is placed at the front end of the magneto, just in front of the ball bearing. Its location there is such as to allow of ready removal. This latter operation is brought about by holding the collector ring with the left hand and using the right to loosen the ring. This is done by means of a coin applied as a slot wrench to free the aforementioned ring. Then the contact breaker cam and high-tension collector ring may both be removed for inspection. Just above the ring, and bearing upon it, is the carbon collector brush. This leads the current up to the vulcanite terminal to the high-tension switch. Between the two is placed the safety spark gap. This serves the most important function of acting as a protector or safeguard against the armature burning out or breaking down. To facilitate its usefulness it is surrounded by a glass cover, through which the size and condition of the spark produced may be observed at any and all times. The gap is unusually substantial, being provided with a number of serrated spark points of steel. These act to make it long lived. The ability to see when the earth spark is working, thus locating or detecting faults, is of inestimable value to any one conversant with magneto ignition. More than this, the gap may be made useful in tuning up and otherwise. The proper space varies between 6 and 7 mm, or between 1-4 in. and 9-32 in.

To remove this, it is only necessary to turn it with the fingers, the connection being by means of fine threads. Like the other parts, the distributor, whether on the inclined or vertical type, may be removed by taking out three small screws. Then the top may be lifted off, the glass protector removed, the distributor disc lifted out, and, if desired, the contact breaker and low-tension cam, also.

Differential Spark Advance for Two Systems—A point which is often brought out against the dual ignition is that the advance for the two should be different. As this entails complications it is usually omitted, the same amount of advance being given for each. In the Hall magneto the correct amount of advance is given to each system, the coil having this movement in an advancing ratio to the magneto. This results in a greater amount of movement being given to the coil contact breaker than to the magneto contact breaker, thus compensating for the small amount of lag in the coil system. It operates on both advance and retard.

As brought out in the two drawings, the drive for the coil-timer-battery system is through the medium of either bevel gears for the inclined type or worm gearing for the vertical. These are constructed with a view of bringing out the noiseless feature, the worm being notable for this, while the bevels are of a material which reduces noise to a minimum. Both run in a bath of oil at all times. In the cut below, the whole construction is made apparent, this being a longitudinal section along the center line of the vertical type. The worm drive and provision for taking up its thrust may be seen clearly at the right.

In Vertical Type, Worm Driving Is Utilized, and Distributor Carried Up Above Magnets

GOOD ROADS: MODERN REQUIREMENTS—AN ENGINEER'S VIEW

By H. TIPPER

THE question of good roads is a vital one to the automobile owner and manufacturer, and it is also a subject of very deep interest to the general public. The automobile is responsible for the problem of revised construction of roads on account of the increased wearing effect which fast-moving traffic has upon a road constructed in the manner usually adopted for highways up to the last year or two. Consequently, the roads engineers are after a more lasting highway, as well as a cessation of the dust nuisance.

The general opinion of road engineers in the Eastern States, and in those parts of the country most largely subject to automobile traffic, is that the old method of constructing roads must be abandoned to a considerable extent, and that brick, cement, and other like materials involve considerations of cost and of doubtful efficiency in this regard, which practically eliminate them from consideration. The result of the investigations of engineers is that the proper surface for the future road will be produced with the incorporation of an elastic material with stone which will eliminate dust and, at the same time, resist the shearing effect produced by the fast-moving automobiles.

Further investigations are necessary to decide the most durable construction of this character, though it has been demonstrated that a most efficient material for this purpose is an asphalt produced in semi-solid form, which can be very economically applied to the road and which will, unquestionably, prevent the dust evil, and, if properly constructed, to a large extent eliminate the excessive deterioration caused by the high-speed traffic.

To Produce the Best Binder—Much difference of opinion exists at the present time as to the exact qualities which are necessary in the asphaltic material to produce the best binder, and a good many contradictory statements are made on this subject. A very general agreement, however, is shown among engineers as to the necessity for using some character of asphaltic material for the purpose of binding the road. This method of construction naturally involves an extra cost over and above the construction of the ordinary macadam road, and it is on the question of how far it will be possible to go in the expenditure of the extra sums of money on the highways that the decision will rest as to what method of construction will be finally adopted.

At the present time there are practically only two methods of construction which are used in this connection, and the relative value of these constructions as a permanent method of surfacing has yet to be decided upon from a point of view of cost and durability. There can be no question, however, that both these methods of construction are a considerable improvement over the ordinary macadam road, and are very much more adapted to the needs both of the automobilist and of the general public.

One of these methods is the pouring of the asphalt material while hot into the broken stone surface of the road, spreading the small screenings on the top and rolling the whole into the broken stone surface until it is all thoroughly bound together.

Another method is accomplished by mixing the broken stone and the asphalt together, laying on the road and then rolling in place with a very heavy roller.

The principal difficulty, and the one which engineers are busily engaged in attempting to solve, is the best character of asphaltic binder to adopt. There has been so much material of a doubtful character thrown on the market with the rapid extension of the problem and the enormous requirement developed, and so many absurd claims are made for materials which have yet to be proved of value, that there is considerable difficulty in deciding upon the best character of material to use.

Complaint in Regard to Oil—A great deal of complaint has been made regarding the use of oil, and much trouble has been experienced by automobilists with the application of this character of oil on the road. The trouble is that oil has been bought without any idea as to its suitability for the purpose and much material of a practically useless character has been dumped on the market merely because it was cheap. This application of cheap oil, to the detriment of the users of the road and those who live near it, will undoubtedly continue for some time until the authorities become much better educated as to the requirements imposed by the conditions of traffic.

It should be remembered, however, that an oil of the proper character, properly laid, is a very efficient dust layer, and when trouble is experienced in this direction it can very usually be traced to the poor character of the oil and, not infrequently, to the poor method of application.

Surfacing an Asphaltic Binder—The same criticism applies to the method of surfacing with an asphaltic binder, and the principal investigation to be carried on is in the direction of standardizing the material and the method of construction so that something of the same general result can be obtained.

As to the greater cost of roads built with the new method of construction, the additional cost for the method usually adopted in the Eastern States runs from $1,500 to $2,000 per mile on a 15-foot road. The maintenance charge, however, on ordinary macadam roads, where there is much automobile traffic, is so heavy—amounting to from $700 to $1,200 per mile per year, according to conditions—that the extra cost of the new method is frequently less than two, and usually less than three, years of the maintenance expense required for ordinary macadam roads, and, at the same time, the road is free from dust and suitable for the traffic.

Experimental Roads—There is a great cry frequently for the laying of strips of experimental road for the purpose of showing what material is best to use. The trouble with laying experimental roads lies in the fact that it is possible to build a road with almost anything, and it will show up fairly well for a month or two, or possibly a year. The real tests of a road lie, not in the way in which it stands up for a few months or a year, but the way in which it answers to the conditions for three or five years, or a longer period.

Experimental roads which have been built for the inspection of various conventions of good roads people and others are subject to the criticism that they have not been built and watched for a sufficient length of time before the inspection to warrant any definite conclusion being drawn for their appearance. The consequence is that the conclusions drawn on these occasions have been very frequently misleading, and roads built after construction of the kind prove to be of little value as a permanent proposition.

It is evident that if the heavy maintenance charge for roads is to be eliminated, the dust nuisance to be prevented, and the road to be kept in something like condition, increased expenditure is necessary for it. It is also evident that a considerable amount of investigation will have to be made to show the best method of construction and to give proper evidence as to the qualities required in a material to suit the new conditions. It is, therefore, desirable and wise to avoid the hasty condemnation or approval of any scheme which is still in the experimental stage, and the most that can be said at the present time is that the road engineers are fully alive to the proposition and are working upon it as quickly as is possible.

The indications are that the road of the future will be a stone road with a practically smooth surface, the surface course being built with an elastic binder, and that the dust evil will, within a few years, be a thing of the past.

BLUE AND BROWN PRINTS

Editor THE AUTOMOBILE.

[2,109]—Will you please answer the following questions through your valuable column of "Letters Interesting, Answered and Discussed": Some time ago I ordered prussiate of potassium for blue printing and received instead, potassium dichromate, with which citrate of iron fails to give the usual results, making a very poor light brown background and very dim brownish white lines. What can I get in the way of chemicals to make a dark brown or black print with clear white lines, like negative paper, for instance? Please give the proportions of the chemicals and method of mixing them.

W. B. CUNNINGHAM.

Lansing, Kansas.

Blue and brown prints differ very much, the chemicals, mixing of them, and the way in which they are used being widely different. Thus, for blue printing, nearly all receipts call for ammonia citrate of iron and red prussiate of potash. These may be made up as separate solutions, and mixed later on, or they may be mixed at first and the whole made up as one solution.

A formula using them together, is: Dissolve 1 oz. of citrate of iron and ammonia and 1 oz. of red prussiate of potash in 8 oz. of water. Dissolve for 10 mins. To use, shake thoroughly and apply to the paper with a sponge or camel's hair brush. This paper may be used as soon as dry, being developed and fixed, all in one operation, simple washing in water.

In the line of black or brown ground instead of blue, there are many processes as follows: Black lines on white (nigrographic process), white lines on black (Willis' platinotype), black lines on white (gallic acid or Shawcross' direct positive process), white lines on black or black lines on white (argentic nitrate process), brown or grayish lines on white (uranium salt process), brown lines on white (Poitevin's gelatine process), dark brown lines on white (Cros & Vergeraud's ammonic bichromate process).

Some of these are very complicated and the chemicals very difficult to obtain, to say nothing of the expense, so that a couple of the more simple ones, only, will be discussed. Thus, the fourth or argentic nitrate, more commonly called silver nitrate, is similar to blue printing solutions and after operation, excepting only the addition of a toning process.

Dissolve 60 grains of silver nitrate in 1 oz. of distilled water, adding 10 drops of a previously made saturate solution of citric acid per oz. of the argentic nitrate solution. Coat the paper with this, dry, and expose in the ordinary manner. Then, after washing several times in clear water, tone for 15 minutes in the following solution: 1 grain auric chloride, 30 grains sodic acetate, 10 oz. water. Wash again not less than three or four times, then fix by soaking for 15 minutes in this solution: 4 oz. sodic hyposulphite 1 pint of water. Finally wash several times to clear off traces of hypo.

Brown or gray lines on white, the uranium nitrate process is easy to use. Sensitize the paper by floating for about 8 mins. in a solution of: 617.2 grains (40 grams) of unanic nitrate, 4.4 pints (250 cc) of distilled water. Expose this paper slightly longer than the ordinary paper, then for a brown copy, float it for 4 mins. in a solution of: 15.43 grains (1 gram) potassic ferricyanide, 2 drops hydric nitrate, 4.4 pints (250 cc) water, after that wash it in slightly acidulated water. For a gray copy, develop by floating in a solution of: 30.86 grains (2 grams), argentic nitrate, 3 or 4 drops acetic acid, .54 pint (40 cc) water. Finally, wash in running water.

Should you ever desire to make prints with blue lines on a white background, coat your paper with a solution of: 3 parts sodic chloride, 8 parts ferric chloride, 4 parts hydrogen tartrate, and 100 parts water. This is thickened by adding 25 parts of powdered gum arabic. After printing, wash in a saturate solution of potassic ferrocyanide, but do not immerse the paper in it, so as to wet both sides, simply float it in the liquid. Wash in water and fix in: 8 parts hydric chloride, 3 parts hydric sulphate, and 100 parts water. Finally wash in water and dry in the usual manner.

In this connection, you will find some interesting reading in the following works, which either touch on this subject in a thorough manner or else give exclusive receipts: Heliography or the Actinic Copying of Engineering Drawings, by B. H. Thwaite, page 312 and following, Proceedings Institute of Civil Engineers (English), Vol. 86; Blue Printing, Etc., Trautwine's Engineers Pocket Book, page 979 and following; Modern Heliographic Processes, Ernst Leitze; Modern Reproductive Graphic Processes, Lieut. J. S. Pettit.

NOISY GEARS DISAGREEABLE

Editor THE AUTOMOBILE:

[2,110]—If possible, will you answer the following questions in your paper, under the heading "Letters Interesting, Answered and Discussed." I have a———— Model F car, 1909 make, which develops a grating, grinding noise when running between 12 and 15 miles per hour. The car runs smoothly up to 12 miles an hour, and makes practically no noise. Beyond that, the gears will grind until 15 miles per hour is reached. Increasing the speed beyond 15 miles results in the noise disappearing again. I have adjusted the differential gears, all kinds of ways, but still the noise remains, and I can not tell where it comes from. The noise which is made is very disagreeable, particularly as I take pride in the quiet running of the car.

W. C. BALL.

Kalamazoo, Mich.

There is a compound made of boxwood sawdust and heavy grease as well as the sawdust in graphite, which will deaden the sound of the gear teeth running together as much as anything you can obtain. The particular noise which you describe, occurring between 12 and 15 miles per hour and at no other time, is, frankly, beyond us.

LIKES $500 CAR IDEA

Editor THE AUTOMOBILE.

[2,111]—The ideas of Mr. Laurie as expressed in his article on "The Possibilities of the Light Runabout" seem to me to be absolutely correct. Not because I have long had the same idea myself in regard to a factory making a good, small, low-priced car to be sold directly to the buyers, but largely because the plan would be so thoroughly cooperative that it must succeed.

Mr. Laurie puts the price of such a runabout at $500. I think that is about the best approximation now possible. To illustrate, there are now at least two fairly good 4-cylinder runabouts selling at $750. This is about $600 to the factory. If the makers can now put out a small number at that figure, certainly a factory making three or four times as many could sell them at $500. And the sales would likely be ten to fifty times the size of either factory now making the cars to sell at $750 list.

I agree decidedly with Mr. Laurie that the runabout should have no rumble seat. And I would likely not advocate the seat as far back as he. I think the rear of a runabout should have a large enclosed carrying space. There is no doubt but what the rapid growth of the automobile industry has stimulated and had parasitic competition, and that this competition has in many instances taken the form of factories making cars to sell to agents, or to users under the title of agents. Many people have bought obscure cars because they could get the agent's discount, whereas, even with the discount off, they were paying more than if they had bought a standard make of automobile at list price. A factory making a good low-priced runabout to sell at $500 and including fully as much real value as any $750 or $800 car on the market to-day, would get all this custom which has so far been a prey for the maker of the flimsy picture automobile.

It would be quite an item to a buyer on the Pacific coast if he could save more than the $100 to $150 freight charges on his automobile by buying from a maker whose prices, by an elimination of the usual expense of selling, were that much below the regular lines of agencied cars.

S. ROSS PARKER.

Seattle, Wash.

MORE ABOUT TWO BEARINGS

Editor THE AUTOMOBILE:

[2,112]—I was recently told that the Chalmers-Detroit "30," 1910 model, only has two bearings on the crankshaft. If this is true, do you consider it an advantage or a disadvantage?

E. E. A. S.

Cambridge, Ohio.

This matter was discussed at some length in the issue of THE AUTOMOBILE for Dec. 2, in answer to a letter. The writer of that letter, however, was not as specific as you, and asked as a matter of general principle. To answer your question directly, the construction as used on the Chalmers-Detroit "30" for 1910 is a good one.

The block cylinder construction possesses many undeniable advantages, and to have the use of them, this is one thing that must be had. In the case you cite, the shaft is made very short and stiff by the omission of the usual center bearing, while the diameter has been increased about 50 per cent. over the size which this motor would necessitate. This double stiffening of the shaft makes it practically unbendable by any strains that may be set up.

You are referred, also, to the letter on this same subject, namely, letter (2,106).

ANSWERED AND DISCUSSED

$500 IDEA IN FLORIDA

Editor THE AUTOMOBILE.

[2,113]—The article by Rolland C. Laurie in your issue of Nov. 18th on "The Possibilities of the Light Runabout," has certainly struck a responsive chord. That there is a large demand for the type of runabout, such as he mentions, there can be no question, and this demand comes not alone from the man of moderate means, but also from the owner of the large car who wants a light, natty runabout which he can drive to and from business and which will save his larger car both in tire upkeep and general wear and tear. A good many manufacturers turn out what they are pleased to term "Runabouts," but they cannot get away from the rumble seat idea and design the car so as to place either a single or double rumble thereon. This immediately opens the door of temptation for the owner to overload his car, and we all know that this is generally done.

I do not know that I could suggest any change in Mr. Laurie's prospective design other than to underslung the springs, so as to bring the runabout closer to the ground and then give the wheels as large a diameter as the general design could accommodate.

I believe that a four-cylinder runabout, thoroughly well built along these lines, and selling for between $500 and $700, would tax the capacity of our largest plant to supply the demand.

ROLLAND M. BARBOUR.
Jacksonville, Fla.

Unconsciously or otherwise, your suggestion hits one of the very few things which the car at $500 cannot have, namely, large diameter wheels. This means large tires, and the cost of tires runs up much faster than the simple ratio of sizes. That is, a 36-in. tire costs more than a 30-in. tire in about the ratio of 50 to 30 rather than 36 to 30. That being the case, very large tires would be out of question, or to put it as you did, very large wheels would be impossible. Even with the present very high prices of rubber, which mean high prices for tires, the chances are that they will go up rather than down, since the supply is not equal to the demand.

GARAGE EQUIPMENT COST

Editor THE AUTOMOBILE:

[2,114]—Will "The Automobile," through "Letters Interesting, Answered and Discussed," give me some idea as to the equipment of a small garage and the cost of the same? I want to know about one equipped for all kinds of repairs, including a vulcanizing plant. Also, what are the usual storage prices?

J. A. C.
San Antonio, Tex.

If you take THE AUTOMOBILE, it would seem as if you have been either away from home or asleep, for the last six or seven weeks an article on this subject has been running in the columns of the paper. As to giving costs, your question is too indefinite to allow of that. Small garage, you know, means so many different sizes. For instance, the writer knows of a man who speaks of his "small" garage, this building being about 60 by 90, and housing six or more cars comfortably. Another speaks of a house 14 by 16 as a "small" garage. Between the two, there is an endless number which might be called small.

A vulcanizing outfit alone need not cost very much money; in fact, these are now made in small sizes for private owners, small enough to be used on the road, and carried along in the tool box at all times. Naturally, the cost of this size is very modest, being less than $10. For a public garage of large size, and equally large capacity, a vulcanizing outfit might run to 50 or 60 times this. Storage charges, also, vary greatly according to location, service and amount of business done or size of the garage. We have heard of dead storage as low as $7 per month. Again, we have heard of storage charges as high as $70.

SELF STARTER DETAILS

Editor THE AUTOMOBILE:

[2,115]—I have read your article on the Winton automatic self-starting device in the issue of "The Automobile" for July 22, but it does not explain fully enough how the device works, that is, how the air is forced into the reserve chamber, and in general, the article does not go into detail. For instance, is a pump used in pumping the air?

A. J. HAGUE, JR.
New York City.

The reason why the complete details of this device were not given in the article to which you refer is because the same thing was used last year and the year before, being described very fully in these columns at that time. We think, too, that you were a little hasty in condemning the article in question as incomplete, since a perusal of the same seems to give all that you ask for. To repeat what was said at that time, "the arrangement is as follows: Tubes running from the first and sixth cylinders carry part of the combustion pressure to a storage tank under the body. Here it is stored until required for starting purposes. The driver then opens a push valve on the dash, and the compressed air rushes through a rotary distributor valve to the two cylinders just over dead center. This pressure pushes down these pistons and, on the occurrence of a spark, the motor starts. The entire mechanism has only one moving part —the distributor valve. An attachment permits tires to be inflated without pump.

Assembled on the dash are: (1) the gage, which shows the amount of pressure stored in the tank; (2) the push button, which allows a pressure to flow from the tank to the cylinders, and (3) a shut-off valve.

From this you will see that no pump is used, the first and sixth cylinders acting as pumps on the explosion strokes. As the compression pressure is about 75 pounds, and the explosion is roughly four times this, a pressure of 300 pounds is thus available, more than the average pump of small size would yield.

USE OF H-T DISTRIBUTOR

Editor THE AUTOMOBILE:

[2,116]—Is there in use, in automobile construction, an ignition system utilizing a single spark coil for two or more cylinders? What is a synchronized coil?

G. E. WARD.
Fort Atkinson, Wis.

Such systems are used very frequently; in fact, every magneto makes use of them. The idea may be briefly explained as follows: The high-tension current, of sufficient strength to jump between the points of a spark-plug, is generated in the outer winding of the coil by rapid pulsations of low-tension current, coming from the batteries or magneto, in the inner winding. When the low-tension current is turned into the coil, the pulsations are caused by the action of the vibrator. In the ordinary system, one coil for each cylinder, the timer turns the low-tension current into the coils in proper order, and the high-tension current from these coils passes directly to their respective spark-plugs.

In the single-coil system, the timer turns the current into the coil whenever a spark is wanted, no matter in which cylinder, and the high-tension current which results is sent to the spark-plugs in turn by a second timing device, usually known as a distributor. Such distributors are regularly on the market. That they are not in more general use for battery ignition is due to the difficulties encountered in properly insulating them.

Practically all magnetos use the single-coil system. If they are what is known as the 'true-high-tension" type, the coil is contained somewhere in the body of the magneto, often being incorporated in the armature. In others the coil is separate. On both types the timer and distributor are carried on the magneto and driven from its shaft. The only exception we know of is the Ford Model T magneto in the flywheel, which uses a standard timer and four separate coils.

By a "synchronized coil" is often meant one of this type, acting for all the cylinders through a distributor. The word "synchronized" has a Greek derivation, meaning literally "at the same time." Its applicability in this sense comes from the fact that with such a coil the spark must take place in each cylinder at relatively the same time on the piston stroke. It is almost impossible to adjust several coils and vibrators to deliver a spark in exactly the same length of time; hence with a multiple-coil system some cylinders are often firing ahead of or behind the others. With a single coil this is impossible.

The term synchronized is also often applied to a multiple-coil system using a common or "master" vibrator, which provides but one adjustment and gives each coil the same amount of current, so that it delivers its spark in the same length of time. This results in sparks regularly timed, just as would be the case with a single coil.

The advantages of the synchronous coil are well recognized, and it would be more used were it not replaced by the magneto.

Appearance of the Forty-Two Horsepower Six-Cylinder Touring Car Is Typical of the 1910 Franklin Line of Cars

CATERING to every need with a wide range of powers, values and bodies, the Franklin line for 1910 is unusually complete, comprising no less than 16 body forms on three separate and distinct chassis. With this universal line of cars, the makers, H. H. Franklin Mfg. Co., Syracuse, N. Y., expect to tax the capacity of the present immense factory to its utmost. To prepare for this widespread demand, the commercial cars have been segrated, and a separate factory obtained for their construction.

As has been the case in the season of 1909, the touring car is made in three models, the largest being a seven-passenger car of 42-horsepower, known as Model H, and the smallest a four-passenger car of 18-horsepower, designated as Model G. Intermediate in size and power is a five-passenger car of 28-horsepower, which is known as Model D. Model H has a six-cylinder and the other models a four-cylinder engine.

A change in construction is noted in the introduction of the car with the close-coupled body, or miniature tonneau, in the 42 and 28-horsepower classes. These close-coupled cars take the place to a considerable extent of last year's runabouts of the same size and power built with a double-rumble seat. The runabout type with a double-rumble seat, however, is retained in both of these models, and in the lowest powered class there is a retention of the runabout in three forms to the exclusion of the more popular close-coupled car, as in the higher powered models.

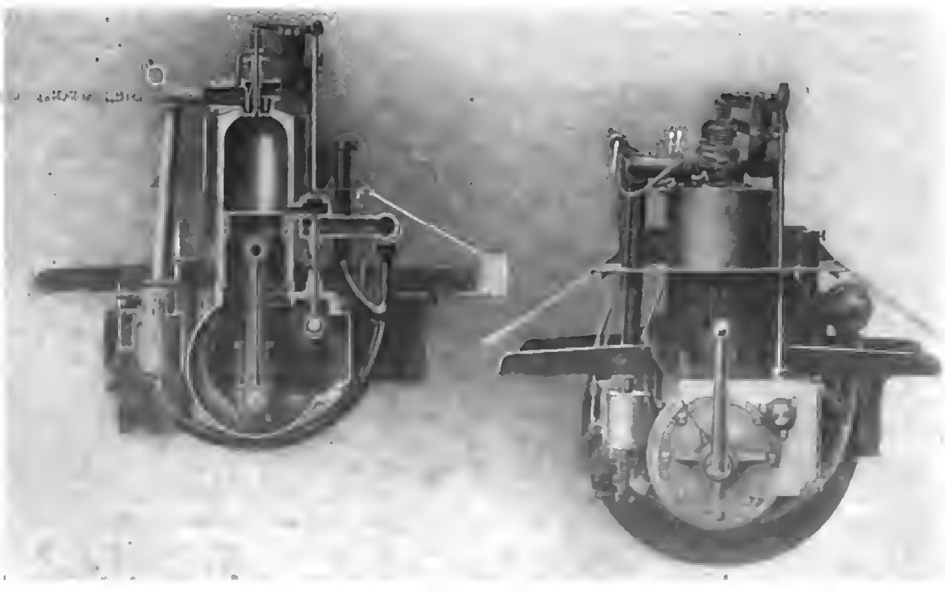
Closed cars appear in six forms, in the largest class being a seven-passenger limousine of 42-horsepower. In the intermediate class are another limousine, having 28-horsepower and carrying six passengers, and a six-passenger landaulet of like power.

Three closed cars are classed by themselves and not among the regular H, D and G models. They are all known as Model K, and each is driven by an 18-horsepower engine. They are a limousine, town car and taxicab, the two former providing respectively for six people and the latter for five. Both town car and taxicab have auxiliary folding seats. The driver's seat in the taxicab is single and the space beside it is large enough to be used for carrying baggage.

Most Noticeable Changes Made in Cooling Method—The changes most noticeable shown in the 1910 models are in the engine, but they are changes that are greater in appearance than in fact. Air-cooled like all its Franklin predecessors, the engine shows a new method of applying to the cylinders the cooling air current. Heretofore each of the cylinders has been encircled by a series of horizontal metal flanges of phosphor bronze shrunk onto the exterior wall. The same idea is carried out in the 1910 motor, but with this difference, that the flanges are vertical instead of horizontal, steel instead of bronze, and are cast into the cylinder instead of being shrunk on.

This makes possible the improvement in the way the current of cooling air is made to envelop the cylinders. In the previous engine the current of air taken from the front of the hood was sent back upon the cylinders by a gear-driven fan. This fan is eliminated now.

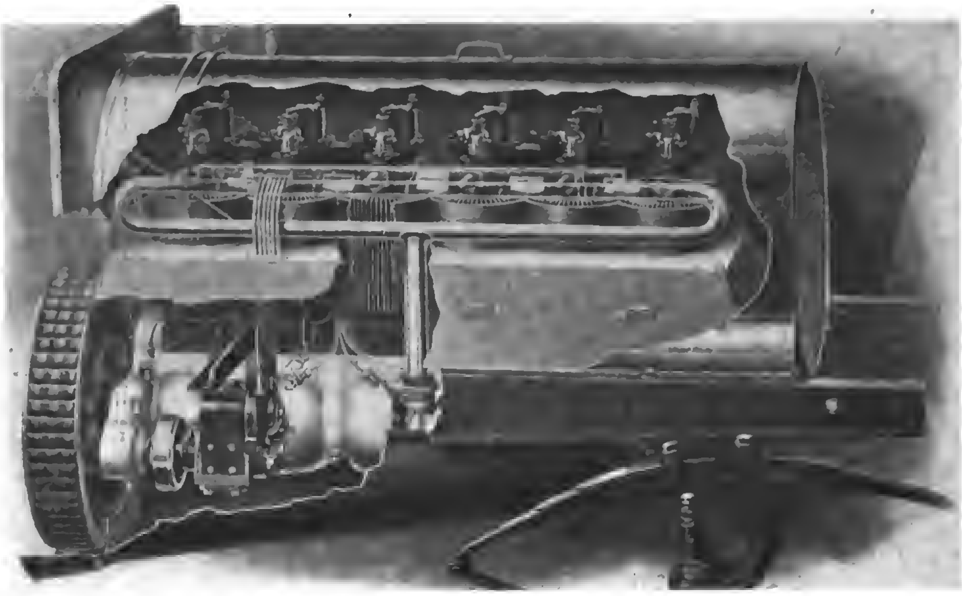
In the 1910 engine each cylinder, with its vertical flanges, is encased in a cylindrical sleeve of sheet metal, and through the tunnel-like opening thus formed, there is drawn from top to bottom a strong current of air by a suction flywheel at the rear of the engine. In order that the necessary suction may be effected, the entire engine base is given a housing of sheet metal. The top of this forms a



Section and End View of Engine Showing New Cooling Scheme

deck extending from the cylinders to the side members of the frame. This with the pan below the engine forms a chamber in which the air pressure is kept less than atmospheric by the flywheel, and thus is produced the partial vacuum necessary to the induction of the air current from above, and down the cylinders.

Powerful New Fan Creates Small Vacuum—This suction fan with its contributary devices creates a current of air far more powerful than that applied in previous engines. Increasing the amount of cooling air about the cylinders and doing it with less power, it increases both the cooling efficiency and the motor efficiency. Each cylinder, regardless of its distance from the opening in the front of the hood, is provided with an equal current of air, of equal temperature, and is equally cooled.



More Complete View of Six-Cylinder Engine Showing Cooling Details

Fan capacity is many times the capacity of the total area around the cylinders, assuring an equal distribution of the air. The air currents are fully controlled and accurately directed to those parts of the engine where they are most needed. Entering at the top, the air, while it is coolest, immediately strikes the valves and the hottest parts giving them a maximum of cooling effect.

Cylinders are cast separately, and each is equipped with the same number of flanges or fins. With the previous method of construction the number of fins was increased as the distance of the cylinder from the source of cooling air increased, this giving greater heat-radiating surface to those cylinders which felt least the effect of the cooling fan.

Rate of conduction is proportional to the area of the section through which conduction takes place, and the 1910 method of casting in the flanges increases this section and thereby aids in producing greater radiation of heat.

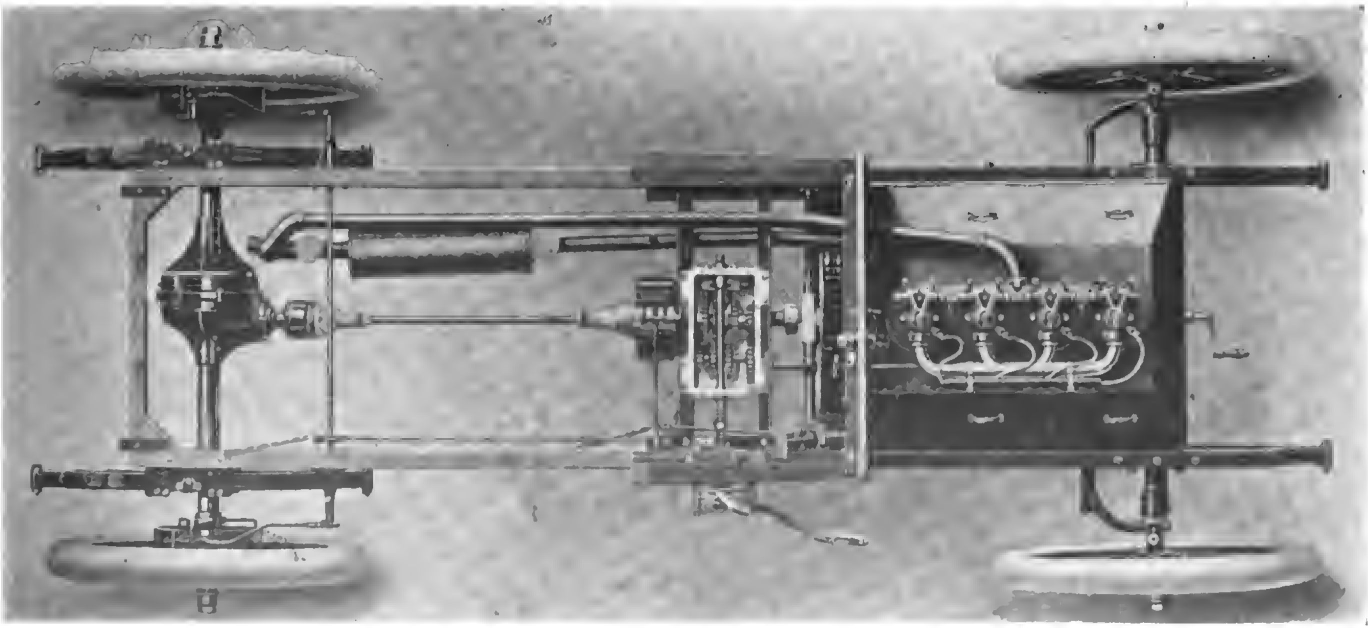
By the new directed or local cooling of the motor the cooling air is kept close to the cylinder wall from the time it enters until it leaves. The number of parts is lessened, the fan by means of which the air current is induced being made an integral part of the surface or rim of the usual flywheel.

In appearance the greatest difference of the new engine from the old is caused by enclosing in sheet metal all of the engine except the cylinder heads in order to produce the cooling suction.

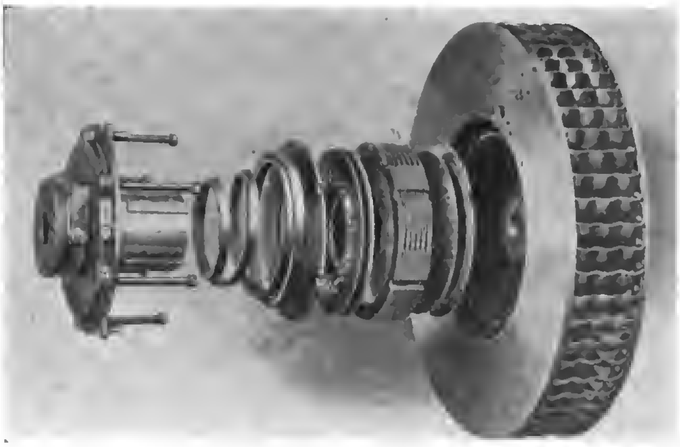
Three constructional features of the engine, which are retained from the models of previous years, are to be seen in an auxiliary exhaust, concentric intake and exhaust valves, and a dome-headed cylinder. Each of these is a considerable factor in the Franklin system of air cooling.

Of these three the auxiliary exhaust contributes most to efficiency in cooling. It opens at the base of the cylinder chamber immediately at the completion of the power stroke. The extent of the work done by it is shown by the fact that through it 71 per cent. of the hot, dead gas is immediately discharged and only 29 per cent. left to be carried out through the main exhaust in the cylinder head and there liberated.

Concentric exhaust and intake valves permit the use of larger valve diameters, which make possible a larger charge. The dome form of the cylinder head is largely made possible by the concentricity of the valves at the summit of the head. The dome form of the interior is a close approach to a spherical interior. The latter is a constructional aim of automobile engineers as it is productive of a minimum of interior or heat absorbing surface without lessening the heat-radiating exterior.



Chassis from above Displays Extreme Simplicity, Compactness, and Small Number of Parts of Franklin Car



Sirocco Flywheel Fan. Multiple Disc Clutch

Multiple Disc Clutch Retained Unchanged—The clutch shows a retention of the multiple disc type, phosphor bronze and steel alternating as the material of the discs. The clutch is within the fan flywheel. When it is engaged the discs are held firmly together by means of a spiral spring.

Carbureter is of the automatic, float-feed type. An improvement in its arrangement is shown in the removal of the primer connection from the dashboard and terminating it in a button at a lower corner of the hood front, where it is most convenient if occasion for its use arises when cranking the engine.

Another improvement in connection with the carbureter is a tributary pipe by which cool air instead of warm may be admitted. For cold weather driving, the air is taken by means of a pipe running from the auxiliary exhaust. In warm weather, this can be closed by a butterfly valve and air of the coolness of the outside atmosphere be taken through the tributary pipe which comes through the top of the engine jacket and which in cold weather is closed by a cap.

One Ignition System and No Spark Advance Lever—A single ignition system, that of the Bosch high tension magneto, is retained for a second year after a season's trial, which has shown it to be the most successful method of ignition. Spark control lever is abandoned on all models. The 18-horsepower cars were last season built with a fixed spark and are again so built for 1910. In the 28 and 42-horsepower classes, with the spark control lever now gone, the magneto is provided with a governor, which controls the ignition up to a speed of twelve miles an hour on the high gear, retarding it automatically at that point to take care of the motor's needs.

Simplicity has always been an aim in Franklin construction, and nothing before has gone farther in the direction of the elimination of complication than the 1910 control. The driver has nothing to handle but the throttle, unless he changes speed.

Throughout the rest of the mechanical part of the motor car the refinement is along lines already well established. There are some changes which serve to strengthen the construction and improve the performance of the car, but none of these is radical. Indicative of this sort of improvement is an increase in the size of the tubular front axle, together with new steering knuckles and arms, the latter being fastened to the knuckles with a taper key, nut, and cotter pins, thus eliminating brazing. Nearly every joint about this front axle is mechanical. The steering yokes on all these models are increased in size.

Progressive Transmission Finally Abandoned—A tendency toward uniformity of construction in the several models is evidenced not only in the ignition but in a number of other particulars. An instance is afforded by the transmission, all models for 1910 being equipped with a selective sliding transmission, whereas last year on the smallest model was used a transmission of the progressive sliding type.

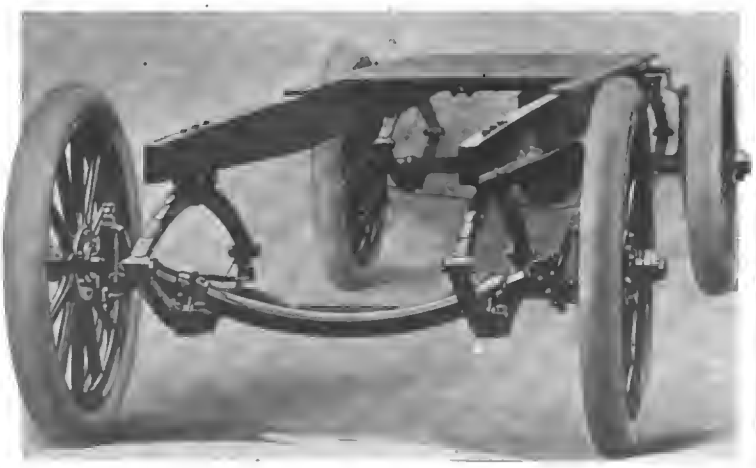
All of the 1910 models have a worm steering gear, which eliminates loss of motion and facilitates handling of the car. In addition the steering device shows a slight change, the steering arm being made to fit the larger steering yoke, and the diagonal steering tube being increased in diameter from seven-eighths of an inch to one inch. The steering wheel of the smallest model is increased in size, so that all are now 17 inches in diameter.

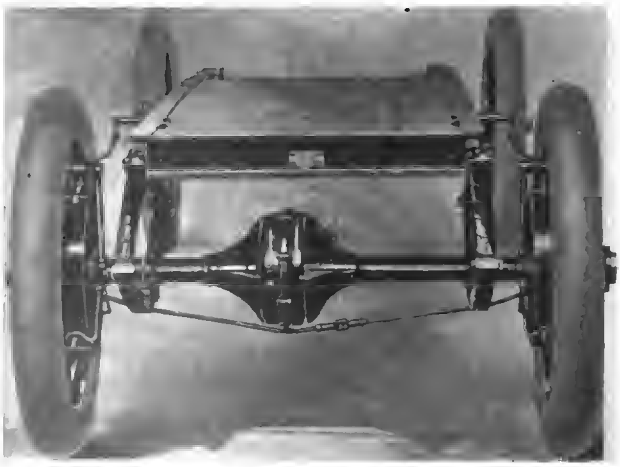
A new feature is an auxiliary oil pump on the dashboard for use in the event of extra oil being required in long stretches of hard going. In the general improvement of lubrication, small grease cups have wherever possible been substituted for oil cups, as at the base of the clutch lever and change-gear lever.

Larger Tires Have Undeniable Advantages—Larger tires are provided in accordance with the construction tendency of the past few years. The larger size serves both to prolong the life of the tire and to increase the riding comfort of the cars. In the securing of easy riding the effect of the large tires is greatly augmented by the laminated-wood chassis frame of all Franklin cars. This frame construction, of layers of selected, second-growth white ash, screwed and glued together, is shown by test to have a strength greater than that of steel.

Tires represent the owner's greatest item of expense of maintenance. The extent to which the makers of the Franklin have gone to eliminate this expense and prolong the life of the tires is seen in extra expense on their part in the providing of the first tires. These are without exception larger than are specified by the tire makers for the weight of car they have to support. The 28-horsepower, for example, weighs in the touring car type 2,200 pounds, but its tire equipment is that commonly specified for 3,300. Thus, this car is a third lighter than the makers would be justified in putting onto its tires.

Light shapely bodies are produced by the use of sheet aluminum. All the touring cars are finished in royal blue, with black running gear and hood and blue wheels. The close-coupled cars and runabouts are finished in red and black.





Front and Rear Axle Construction, Displaying Also Spring Suspension and Laminated Wood Frame

One of the Rainier Novelties for 1910 Is an Excellent Example of the Touring Body with a Torpedo Effect

FOUR touring car models and two enclosed bodies, all on the same chassis constitute the vital points; the meat, as it were, of the announcement of Rainier cars for 1910, as given out by the Rainier Motor Company, with factory at Saginaw, Mich., and offices in New York City. Chassis for all the models, except the baby tonneau, is identical, while the power equipment in all these models is the same—consisting of 45-50-horsepower engine of the four-cylinder, four-cycle type.

Of the models, one is a distinct innovation. This is the enclosed touring car. The plans call for the enclosure of the front seat as well as of the tonneau, with a door opening on the left side beside the owner's seat and a solid panel on the right side beside the driver. The panel is somewhat lower than the door line in order to permit the easy handling of the levers, but the extra door on the left-hand side is the same height as the tonneau door, making a very pleasing continuous straight line from the dashboard to the tonneau.

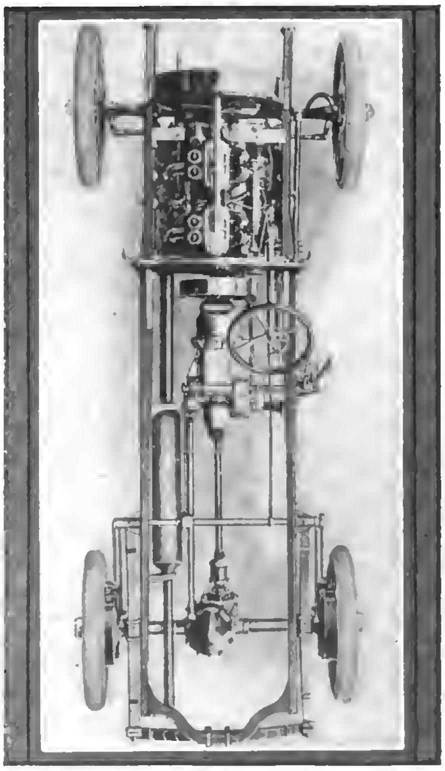
Advantages of the enclosure are obvious. It protects the occupants of the front seat from wind and weather, and makes the riding there as comfortable as within the tonneau. The regular touring model is also furnished, as well as baby tonneau and close coupled car.

Letters from owners, not only in the United States, but in Canada, South America and Europe, attest that the cars were singularly free from mechanical trouble. They were capable of high speeds, of great endurance, were wonderfully regular and reliable and have plenty of power on hills.

Recently in public contests the car has demonstated its reliability and endurance. Notably in the 24-hour race at Brighton Beach this year and in the New York-to-Atlanta run. In the last 24-hour race it covered 57 miles in an hour, breaking the one-hour record, and running a total of 1,115 miles, which broke the record for continuous 24-hour running.

Unusually Successful in Races the Past Season—In the race at Atlanta for the Atlanta Trophy, which was the most coveted trophy of the week, it ran 200 miles in 173 minutes, at the rate of nearly 70 miles an hour, and finished the race without a stop, with scarcely any evidence of wear on the tires and with no mechanical difficulty. In fact, the speed of the car for successive laps varied less than five seconds, while the second hundred miles was made 43 seconds faster than the first hundred, while all records in its class—over 150 miles—were broken. In fact, this speed has never been excelled in races of this distance except by high-power racing cars.

As a basis for this success was the correct design, careful workmanship and best materials. It is built in three units: the power unit, the clutch, transmission and universal joint in the second, and the cardan shaft and rear axle in the third.



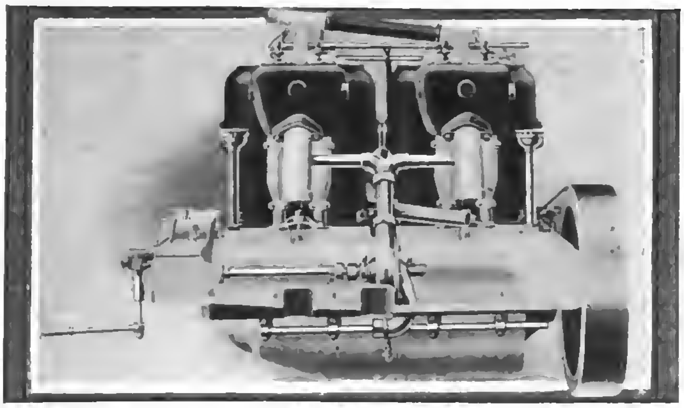
Chassis from Above Shows All Features

Very Few Changes Needed for 1910—Among the units the engine is unchanged, other than the lubricating system, which has been simplified, thus securing improved economy and more effective lubrication. The notable point about this unit is accessibility, as the chassis photograph shows.

A change has been made in the transmission unit to secure greater accessibility and slightly better distribution of weight, whereby the transmission and clutch are housed in a single case with a partition to prevent oil passing from one part to the other. The addition of the helix or screw thread to the clutch effects a notable improvement.

Changed also is the rear axle design in order to obtain greater accessibility, while the brake application has been altered to secure larger braking surface and greater rigidity. The front axle design has been modified so that the steering cross-rods are brought behind the front axle and protected by it from striking obstacles in the road.

Large-sized Engine Affords Much Power—The motor is of the four-cylinder type, 5-inch bore and 5 1-2-inch stroke. Cylinders are cast in pairs with liberal water jackets. The valves are of



Engine Has Distinctive Look, Due to Enclosed Valve Springs

large diameter, located on opposite sides, and interchangable.

Cams are integral with the camshaft. The camshafts run on special bronze bearings. The crankshaft is cut from a solid bar of nickel steel.

Main engine bearings and connecting rod bearings are bronze with babbitt interlining of the inserted type, the most durable bearings known. The oil reservoir is at the bottom of the crankcase, with a groove under each connecting-rod bearing. An oil pump secures circulation, while the system of lubrication practically eliminates all external pipes.

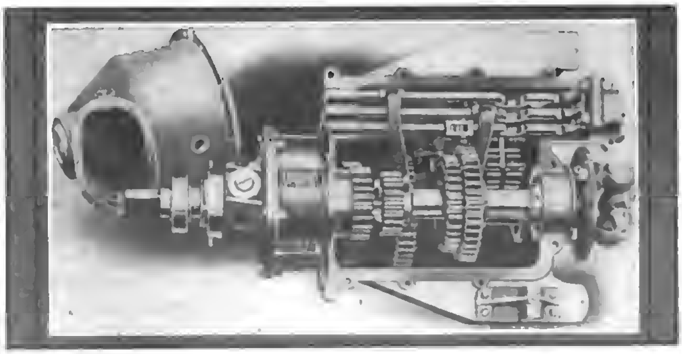
Water circulation is effected by a gear pump of the bucket type, while a fan assists in cooling. Make-and-break system of ignition, simplified, which has been so successful in the Rainier car for the past three years, is continued. This ignition system is believed to increase the efficiency of the engine at least 10 per cent. The spark is more positive and avoids the trouble with timing. It has been so reliable as to attract widespread attention.

Clutch is a multiple disc with alternate steel and bronze discs, operated through a helix which causes it to engage softly and increase its power as the load on the engine increases, so that the danger of slipping is impossible. A handhole at the top of the housing permits easy adjustment or examination.

Four-Speed Selective Gear Box—The transmission works of the selective plan, four speeds being provided with direct on third speed. The shafts and gears are of nickel steel, the latter being bolted up to integral flanges on the former. Shafts run on annular ball bearings, while removable covers permit ready examination or lubrication. The entire case is hung from three points.

Cardan shaft transmits the power practically in a straight line to the rear axle. Differential is the bevel gear and pinion type. Full floating rear axle is used. A live axle is carried within a tubular axle, on which the double ball wheel bearings are mounted, the tubular axle carrying the weight of the car. A double "V"-shaped torsion rod parallels the propelling shaft. Double ball bearings are used in the wheels and single ball bearings in the differential and propeller shaft.

The rear spring suspension is the platform type, with three springs supporting the weight of the body. The front spring is

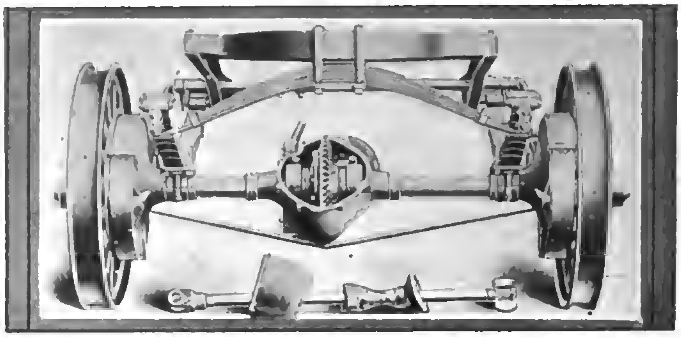


How the Four-Speed Selective Transmission Appears

the semi-elliptic type. This spring suspension coupled with the admirable weight distribution of the car produces very easy riding qualities.

Front axle is a solid drop-forging of I-beam section. The front wheels are mounted on double ball bearings. The brakes are very large; one external contracting and one internal expanding, both operated on drums bolted to the spokes of the rear wheel.

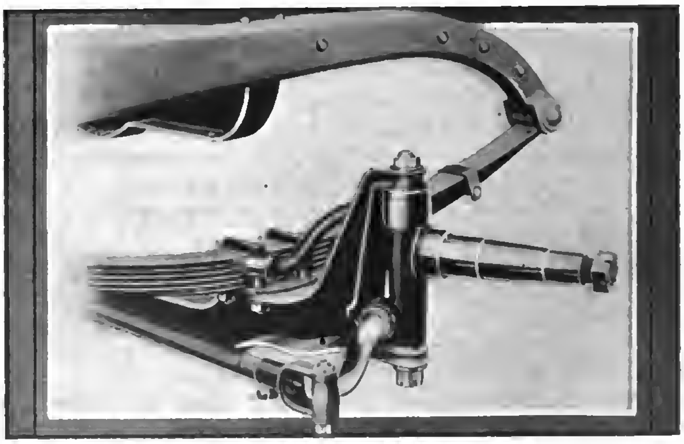
Steering mechanism is of the worm-and-nut type, with reach rods and knuckles of nickel steel. Wheels are 36 inches front



Rear End of Chassis, Showing Rear Spring Suspension

and rear, carrying 4-inch tires front and 4 1-2-inch tires in the rear. The frame is pressed nickel-steel and drops 2 1-2 inches forward of the rear axle. Has four cross-members. The weight of the car is 3,000 pounds, which is exceedingly light in view of its strength, and reduces wear and tear and tire cost to a minimum, giving also very low cost of operation and maintenance.

In the picture of the front axle below, will be noted the specially dropped front cross member of the frame, this acting as the support for the radiator, as well as stiffening the front



Front Axle and Steering Pivot Look Husky Enough

end of the frame. It is of pressed steel, channel section, with the open side turned to the front, and riveted to the main frame by hot riveting. Even should the rivets part, the shape and fitting of the member are such that it could not drop out of place or be deranged in any manner, but would continue in the same position, although the strength as a stiffener would, of course, be impaired.

Similar remarks apply to the rear cross member, which may be seen in the view of the rear part of the chassis above. This is of the same channel section, turned in, and is fitted into the open inside of the side members. This fitting is carefully done, so that the member really is a driving fit there.

Attention is called to the enclosing of the valve springs, as visible in the engine picture. This is in line with the modern demand for the ultra-silent machine, deadening as it does the noise of the valve motion.

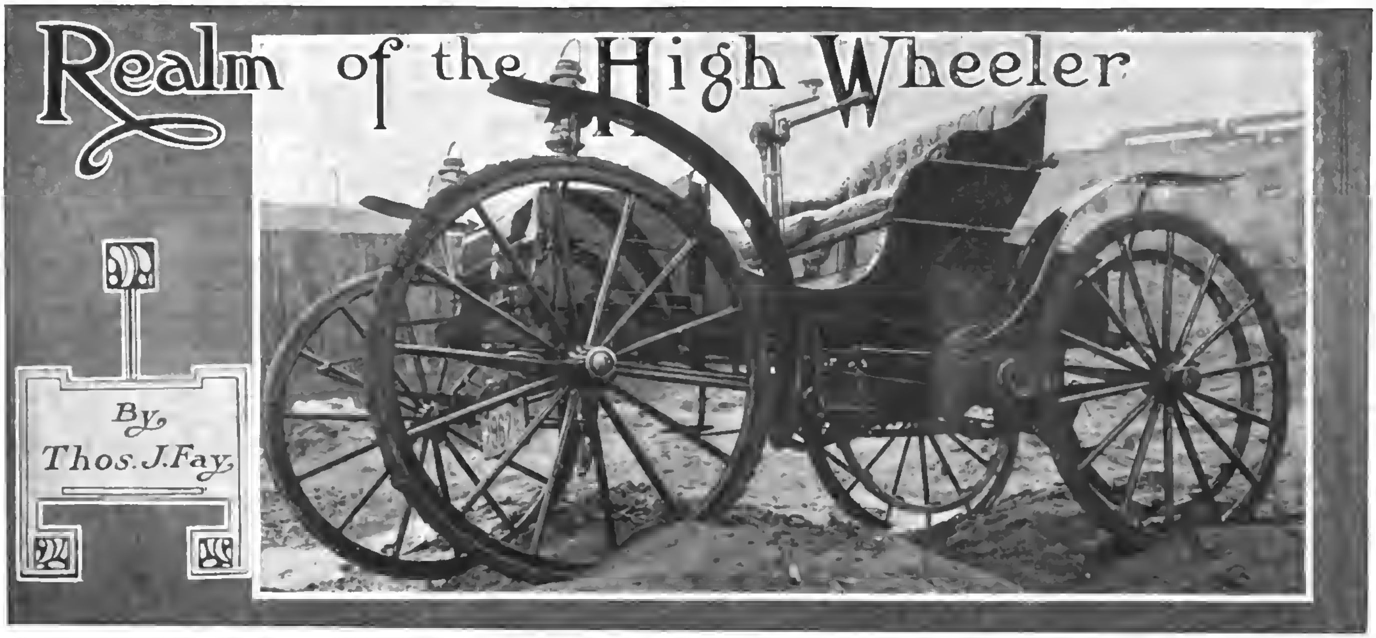


Fig. 1—Holsman high wheel car after doing stunts in a vacant lot which is being filled, making the going difficult

PRIOR to the introduction of pneumatic and solid rubber tires, during the long period of years when the cost of steel tires was but slightly different for the respective sizes of wheels, carriage and wagon makers resorted to the use of what is now dubbed "high wheels." Reasoning backwards, and it is plain to be seen that wheels, for carriages, in the absence of rubber tires, were made in the larger diameters simply because the service rendered by them was more in keeping with the requirements.

When pneumatic tires came into vogue it was found that they increased in cost enormously with diameter and the real question was: How small could they be and still do good work? At first they were made much smaller than after-experience indicated that they should be, and in late years the trend has been in the direction of greater diameter and a more liberal section for good and sufficient reasons, as follows:

Life of a Tire Properly Considered

(A) Is proportional to $2\pi R$;
(B) Considering S^2;
(C) Involving the sine of the angle of impact;
(D) Weight of car and its distribution;
(E) Square of the velocity of the car;
(F) Resistance offered by the impact medium;
(G) Quality of material used in tire;
(H) Manner of use of the material.

The conditions D, E, F, G, and H are not under the control of the maker of tires, but the designer of the car will be in a position to influence the situation by a proper display of skill. If the weight of the car is held within proper bounds, this circumstance will be nearly as important as the proper distribution of that weight; if the motor is of great power, the effect of speed, being a "square" value, it is at once apparent that life of the tires will be much more affected by power of the motor than it will be by properly distributed weight on the road wheels.

The condition F is neither under the control of the designer of the car nor the maker of the tires; this is a matter of road building pure and simple. The quality of material used in the tires may be controlled by the maker thereof, but this phase of the problem is not a matter that can be construed as an argument in favor of any type of vehicle; it is a tire maker's undertaking pure and simple. The condition H is partly up to the maker of the tires, and largely in the hands of the designer of the car, although the user is responsible for the ills of indifferent up-keep.

In view of what has been said it is self-evident that the conditions A, B and C (within limits) will dictate as to the best diameters of road wheels, but there must be a limit to diameter for reasons entirely beside the question of the life of the tires. In any case, since R is taken to represent the radius of the wheel, the angle of impact of the tread of the tire with a road obstruction is far from unfavorable after the wheels are brought up to a certain diameter, because the road obstructions, even under severe conditions, are limited as to height and abruptness.

The Wisdom of Selection Involves Diameter—Experience has shown that pneumatic tires will do the same service that may be expected from high wheels and solid tires, even when the pneumatics are considerably less in diameter, but they have to be of far greater section S in order that the value of S^2 will make up for the deficiency in the direction of $2\pi R$. If, however, the height of the road obstruction is excessive, increasing the section S, even to extremes, will not compensate for the deficit, due to the sine law involved; under such conditions, because of the wide angle of impact, high wheels are bound to do better work, and the higher the speed of the car the more marked will be the gain, although it must be remembered that flywheel effect may become a factor.

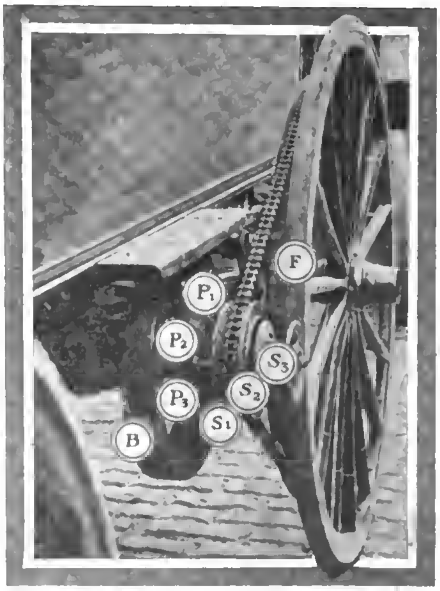

Fig. 2—Side chain drive, attached to a delivery wagon, showing chain of special construction running in shieves

Flywheel effect is just the same for one diameter of wheel as another, provided the peripheral velocity is constant, as it will be, for a given speed of the car in miles per hour; the possible difference in flywheel effect then will come in on account of difference in materials used in the respective tires—pneumatic vs. solids.

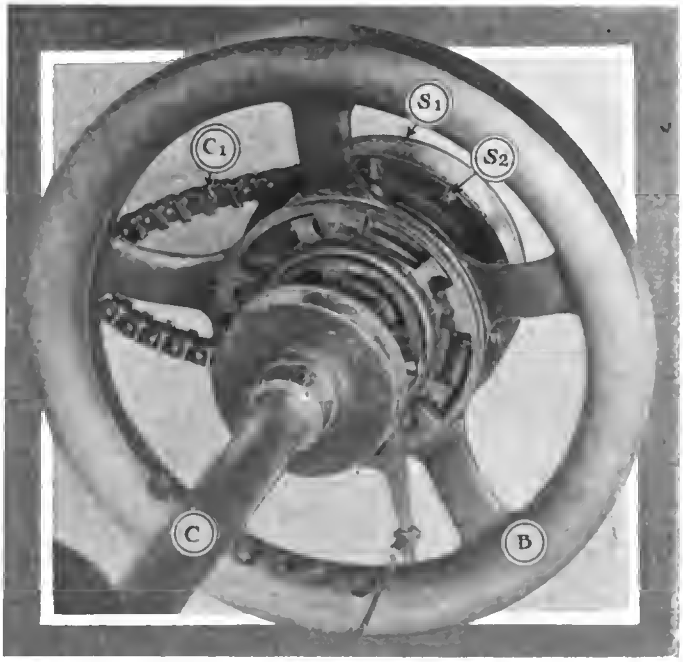

Fig. 3—View of side chain drive form back of flywheel showing how the control cable is attached to lever system

Stock Arguments Dictated by the Dollar Sign—From what has been said it would seem as if the cost of tires, since it increases enormously with diameter, is the prime reason for limiting the same, not forgetting that there are compensating factors:

(A) Pneumatic tires, because of the elastic properties of air, will render greater service per cubic inch of tire volume than will be possible when less elastic material, as when rubber compound, is used in the absence of an air cushion.

(B) With wheels of relatively great diameter, it is a detriment more than a gain, to employ tires of great section.

From the point of view of cost, then, pneumatic tires lend facility, since they will do good work even with a reduced diameter, and solid tires work better when the section is very limited, so that the increased diameter, which is a foundation for the better service, demands the use of a reduced section, which is, of course, followed by a reduction in cost.

Present Practice Seems to Be on High Ground—Disregarding, for the time, such attempts as involve trying to convert a horse-drawn rig into an automobile, it will be possible to review the situation and ascertain to what extent good mechanics adorn this branch of the industry. The process will, of necessity, require a concrete illustration, and the Holsman Automobile Company, Chicago, Ill., has consented to such an examination of the plant as will afford the desired amount of light.

Holsman products includes not only the type of car as shown in Fig. 1, but enclosed body work, as a coupé type and a line of delivery wagons and other commercial rigs as well. Fig. 2 is of a delivery wagon, showing the transmission, by means of a Holsman chain, and it is in this chain that much of the success of the system lies. An ordinary sprocket chain would not serve the purpose, for in Holsman cars the chain engages the sides of friction discs at an angle of about 15 degrees on high speed, and the chain must be so shaped as to afford contact, under proper conditions, with the faces (in juxtaposition) and referring again to Fig. 2, the shieve-plates *S1* and *S2* are so related to each other that they may be spread apart or brought into closer axle-wise relation, and in this arrangement is the facility for alter-

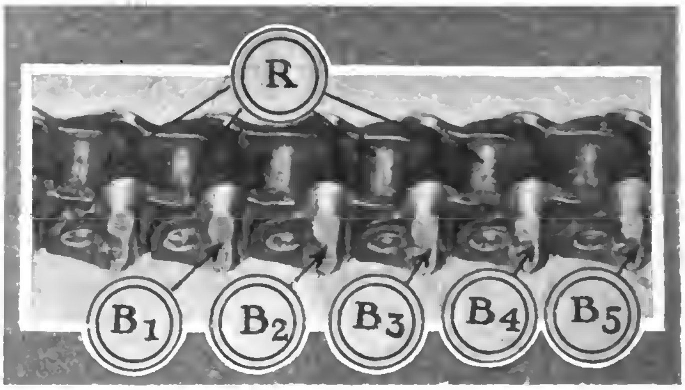

Fig. 4—Section of chain showing how links are bulged and so finished as to run in grooves of shieves

ing the lever advantage for the purpose of changing speeds when the car is moving in the forward direction. If the plates *S1* and *S2* are closed in, the chain will be crowded out toward the periphery and the speed of the car, for a given angular velocity of the motor, will be increased; likewise, spreading the discs will have the reverse effect.

This method of changing speeds is limited, and if low gear, so called, is to be let in, this is done by letting the chain down on a

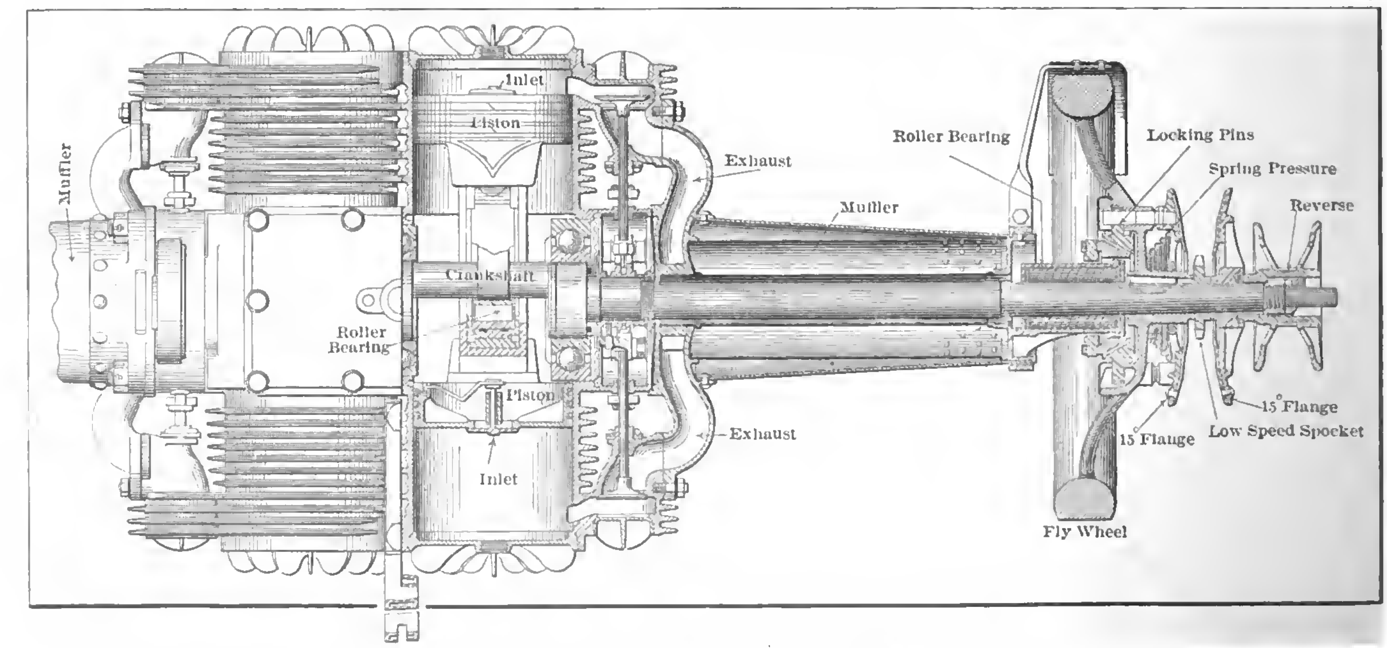

Fig. 5—Holsman type of motor in part section with one end broken off, but presenting evidences of use of ball or roller bearings at every point and other novel features

sprocket pinion, which lies under the chain, and is keyed to the shaft. The mere spreading of the discs *S1* and *S2* will allow the chain to settle down on the sprocket pinion, and the same motion of the lever system, under the control of the driver, pushes the motor forward on its ways, so that the chain will tighten up properly.

In going into reverse all that is necessary is to slide the motor in the direction of the rear wheels, when a set of forks (one of which is partly shown at *F*) will support the chain, while the shieve *S3* will engage the tire of the road wheel.

Both sides (for the side-chain drive) are symmetrical, and the motor is provided with two flywheels, one of which is designated as *B* in the figure. When the engagement is for high gear, so called, locking pins *P1*, *P2*, *P3*, etc., around the motor shieve, are thrown into engagement, and since they register with holes in a fixed member, the work comes on them and the shieve is positively locked. The reverse side of the motor shieve, including one of the flywheels, is pictured in Fig. 3, in which *C* is the extension of the crankshaft, *B* the balance wheel (on one end, there being two), *C1* is the chain, and *S1* and *S2* are the two members of the shieve plates, as referred to in Fig. 2.

How the Chain Differs from Other Sprocket Chains—Referring to Fig. 4, of a section of the chain, it will be observed that the side bars or links of the chain instead of being flat as they would be in regular sprocket chains, are bulged out at *B1*, *B2*, *B3*, *B4*, *B5*, etc., for each link, and the links on both sides of the chain are identical. These faces, produced by bulging the links out, in the manner as shown, are accurately finished and conform to the 15-degree angle of the faces of the shieves for the purpose of engaging, and the drive is made in this way. In all other respects the chain is identical with the more common forms of sprocket chains, excepting that the material is selected for strength and great hardness. The rivets are shouldered in the customary manner and the rollers *R* are of the right size to drop into the small sprocket pinion which is placed to afford a positive low-speed drive.

Unique Plan of the Power Plant—In any further consideration of the Holsman system it will be necessary to note the entire absence of a transmission gear, differential or other means of transmitting the power of the motor. Fig. 5 is of the motor, which is of the four-cylinder, horizontal, air-cooled type, which, in the chassis, is swung across beneath, and the distance from center to center of the shieves on the extensions of the crankshaft registers with the distance from center to center of the driven shieves on the rear road wheels of the car.

Ball or Roller Bearings Used Throughout—As Fig. 6 shows, in substantiation of Fig. 5, there are no plain bearings used, and one of the novel features lies in the use of an annular type of crankpin ball bearing, as, Fig. 6, placed to take the pressure of the crankpin. This bearing is placed on the crankshaft over the pin and presses against rocking shoes nested in the connecting member between the two pistons. The rocker is provided with teeth, engaging teeth on the connecting member, so that the rocker cannot displace, and the whole system, in view of the hard quality of the material used for the pressure faces, as well as accuracy of workmanship, works with a precision and so noiselessly that it is to be commended.

The exhaust, as will be observed in Fig. 5, makes its exit from each pair of cylinders to two mufflers, at the two ends, with the mufflers placed in concentric relation to the crankshaft extensions; this adds to the compactness of the power plant and lends facility to the system by which the motor is shifted back and forth on its cradle for the purpose of maintaining the right tension of the driving chains.

High Aims in the Process of Manufacture—It being the idea in this article to discuss the manufacturing problem rather than the details of rigs, many interesting features of the rigs will be omitted. Many autoists labor under the impression that the high-wheel industry is more or less impregnated with makeshift methods, and some of them claim that the industry is devoted to the adaptation of motors to horse-drawn vehicles.

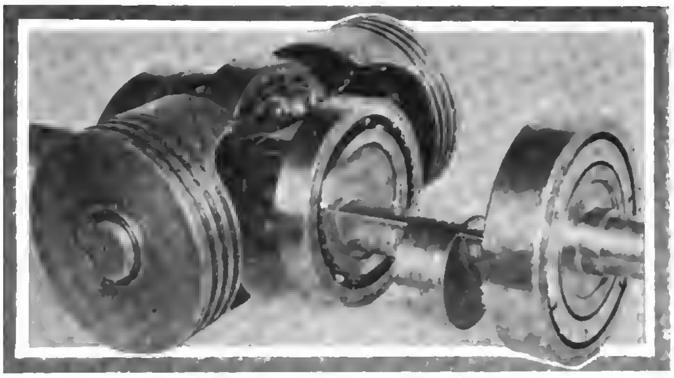

Fig. 6—Crankshaft, pistons and connections between, as used in four-cylinder type of motor

This method of reasoning, as we shall presently see, is contrary to fact, and what the real situation shows is a system of manufacture that carries with it every scientific device known to manufacture that can, by any reasonable chance, improve the product and assure interchangeability of parts. These methods also possess the advantage of reducing cost, and the designer, holding to the contention that high-wheeled rigs have a wide use, has kept uppermost in mind the class of men who prefer rigs of this character, and simplicity is the keynote.

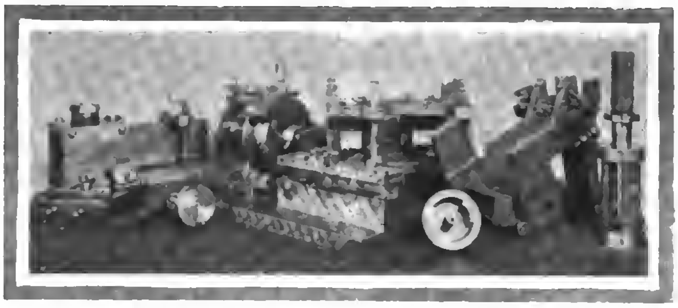

Fig. 7—Some jigs, picked out at random, from tool room, in which a jig will be found for every important operation

Special Grades of Steel Are Used—There would be no object in incurring the cost of a heat-treatment equipment were it not the aim to employ special grades of steel in the cars. Fig. 8 was reproduced from a photograph taken of a corner of the heat-treatment room, and the Brown and Sharp furnaces, as shown, are run under the guidance of a pyrometer which was taken out of its case and shows in the open to the right of the illustration.

Fig. 8—Brown and Sharp furnaces used in heat treating and a pyrometer to tell the tale of temperature

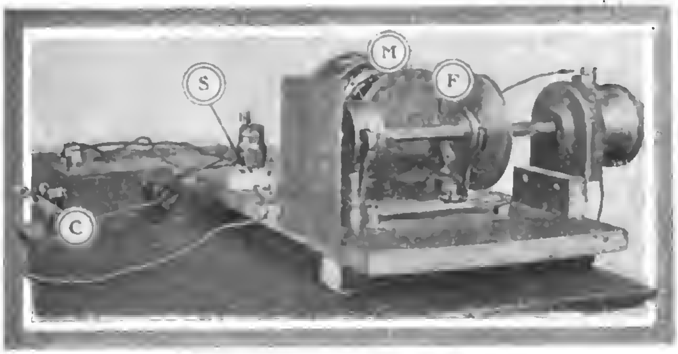

Fig. 9—Instrument devised by Holsman for determining the lag of spark coils

The equipment includes every facility for heating, quenching, annealing, tempering, and cementing the parts of great responsibility, as used in the Holsman cars, and it is only necessary to point out that the making of sprocket chains, roller bearings, and like parts can only be successfully undertaken in a well-equipped plant. In the laboratory, contrary to the usual expectation, means are at hand to examine into every detail of the work, and Fig. 9, of a testing equipment used to determine the "lag" in spark coils is a good indication of the extent to which testing is done in this plant. In this instrument means are afforded to test the lag of coils at speeds even above 3,000 revolutions per minute, and referring to the figure, *M* is an electric motor which furnishes the driving power and is capable of speeding up beyond the highest required range. Incidental speed changes are made through the disc transmission *F* by the simple expedient of sliding the driven friction disc across the face of the driving friction disc. The lamp socket *S* serves as a switch in the electrical system, and the coil *C* is undergoing test.

The lag of the spark is accurately measured, and Fig. 10 is a curve plotted from the coil, reaching the high point of 3,030 revolutions per minute. As the curve shows, the lag reached to a maximum of 49 degrees, as shown by the ordinates, when the speed was 3,030 revolutions per minute, after which the coil failed to work and the spark occurred at the timer instead. Up to 2,600 revolutions per minute the lag was almost in direct proportion to speed, as shown by the nearly tangent relation of the spark points on the chart.

Grinding Assures Accuracy of Finish Dimensions—It is not necessary to picture the whole shop and all the machine tools to indicate the nature of the process and the standard to which the artisans are keyed up to; Fig. 11, of a grinder, with divers crankshafts to the right, is ample indication of the process in vogue. Every part, if it has a concentric relation and can be set up in centers in the grinders, is rough machined and then ground; this grinding process affords a fine finish appearance, but it does more, it enables the workman to come down to a fraction of a thousandth of an inch with the same facility that a good man on a lathe can come within a sixty-fourth of an inch of the finished diameter.

The plan, then, in view of grinding as the final method of finishing, is to use rigid machine tools for roughing out, and they are intended to rip off metal at the highest possible speed, using alloy-steel cutters in rigid tool-posts, and such other necessities as experience dictates.

Some of the Material Specifications—Nickel steel is used to quite some extent, and it must conform to the specifications as follows:

Open-hearth, cold-drawn steel, special analysis:
Nickel, 3.50.
Manganese, .50.
Carbon, 30 to 40, aim at 35.
Silicon, about .01.
Phosphorus, under 0.02.
Sulphur, under 0.02.

Must test to 175,000 pounds tensile strength per square inch after heat treatment.

In parts to be cemented every effort is made to select a grade of steel that can be relied upon to take on a hard shell, and while the core must be relatively soft and dynamic in character, even so, it is considered necessary to afford a fairly rigid foundation for the shell. This material, while it is, in some instances, alloyed, is also in carbon steel, and the selections made are on a basis of well-regulated carbon in a definite and satisfactory field very low in metalloids.

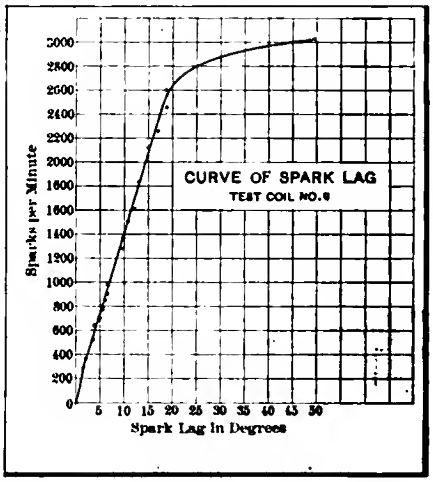

Fig. 10—Curve of lag of a coil that failed to come up to Holsman ideas of quality

All along the line, despite the ideas of those who have not looked closely into the question, the materials are carefully selected, and that it is necessary to do so is assured if the rigs are to perform in a proper and satisfactory manner. In view of the positive indications here included, it is not considered necessary to pursue this phase of the discussion further, on the ground that readers who take enough interest in the matter to appreciate the value of the processes exhibited will be satisfied

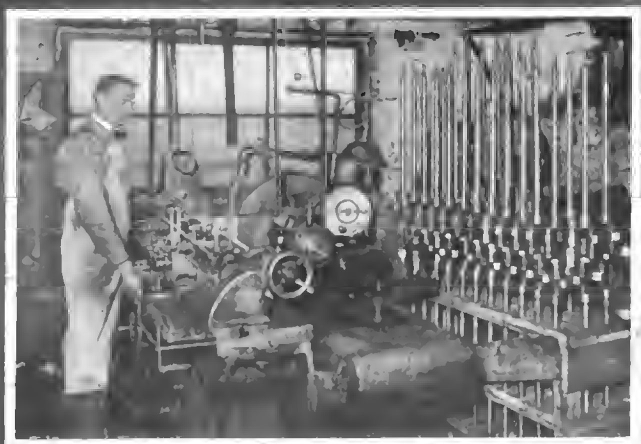

Fig. 11—Grinding crankshafts to within three ten-thousandths of dead accuracy

Fig. 12—Where motors are tuned up, showing two rows of test stands and fans to absorb power

that engineers who work along the lines indicated will hardly be likely to fall below the standard set when it comes to the minor particulars.

Every Motor Is Tested Before Entering the Chassis—Fig. 12 is of the interior of the motor test room, and with test stands in two rows, in each side of the room, with a capacity of 12 motors at one time, the work of testing is readily done and it is a relatively simple task to make a run under several conditions of load for each motor. The stands are cast from gray iron, and the load is put on the motors by means of fans *F, F, F,* etc., which are fashioned out of fairly heavy sheet steel, forming the vanes by the simple process of cutting around three sides and bending the metal over to a right angle from the plane of the discs of steel. These air propellers are riveted to hubs and keyed onto shafts to which the extension of the crankshaft of the motor to be tested is coupled in each individual case. The fans are so designed that they load the motors when the speed is that desired under normal running conditions, and by a system of calibration which has been devised, intermediate known loads are applied in order to be able to adjust the carbureters for the best average results, all of which is accomplished in the most simple and reliable way with evidences of stability.

WITH HIGH WHEELS THE WHEELBASE MAY BE SHORTER

By H. K. HOLSMAN, Engineer, The Holsman Automobile Company.

HIGH-WHEELED automobiles are often confused with that peculiar type of vehicle which belongs to neither the high-wheeled nor pneumatic-tired class, and is therefore lacking in the virtues of either, while possessing many salient faults belonging entirely to itself.

True high-wheeled automobiles must have wheels of sufficient diameter and resiliency to give the necessary riding qualities and to protect the machine from injury from road shock. It has been my experience that in order to gain these results it is necessary to use a wheel of at least 40 inches in diameter. The increase in diameter of a wheel not only furnishes a spoke of sufficient length to give the necessary resiliency, but also produces the effect of an increased wheel base, inasmuch as the vertical motion of the wheel in rolling over uneven surface will be found to be in about exact proportion to the diameter, so far as the motion affects the occupants of the vehicle, and therefore a car equipped with 48-inch wheels and having a wheel base of 60 inches would possess all of the riding qualities of 120-inch wheel base mounted on wheels of one-half that diameter. Of course, the machine itself is also relieved from the severe vibration which would be due to the greater vertical movement, and a little road experience is enough to establish the fact.

It is a well-known fact that it requires less power to drive a high wheel than a low wheel over the same road, the difference being inversely as the diameter. It is also true that the high wheel is much more easily steered, and that on account of its yielding qualities the side vibration is taken up.

Contrary to the general belief, rubber tires of small section are employed on this type of car, not because of their lesser cost but because tires of greater section are an actual disadvantage—first, on account of the disagreeable bounce of the wheel fitted with the large tire, and, second, because of the fact that small tires can be driven where it would be impossible to drive a larger one.

Present high-wheeled automobiles were originally designed for localities where the roads were so poor that the pneumatic-tired machine could not be used. It is the equal, if not the superior, of the low-wheeled type on well-paved streets, and, while the low-wheeled car is limited to highways in more or less good condition, the high-wheeled car may be operated over exceedingly rough roads, deep mud or snow, with little or no inconvenience. There is a perceptible lessening of prejudice in favor of the low-wheeled car owing to the gradual awakening of the public to its limitations, and the increasing recognition of the possibilities of its high-wheeled brother.

THE AUTOMOBILE CALENDAR

Dec. 25-Jan. 1....Columbus, O., Automobile Show, Columbus Automobile Club.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows' Building.

Jan. 17-22........Kansas City, Mo., Annual Automobile Show of the Motor Car Trade Association of Kansas City. P. S. Sutermeister, Secretary, Midland Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Jan. 24-31........Washington, D. C., Automobile and Aeronautical Show, Washington Automobile Dealers' Ass'n.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South Street.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Secretary.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 12-19......Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

March 21-30......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Manager, 760 Main Street.

Races, Hill Climbs, Etc.

Dec. 12...........Los Angeles, Cal., Six-hour Race, Los Angeles Motor Racing Association, Los Angeles, Cal.

Dec. 14-18........Dallas Endurance Run, The Implement & Vehicle Journal, Dallas, Tex.

Dec. 17-18........Indianapolis Motor Speedway, Race Meet. Ernest A. Moross, Director of Contests, the Motor Speedway, Indianapolis.

Dec 22-29.........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

Spaciousness Shown in General View of the Plant of the Mora Motor Car Company, at Newark, New York

MODERN FACTORIES, AS EXEMPLIFIED BY THE MORA PLANT

NEWARK, N. Y., the location of the factory of the Mora Motor Car Company, lies within a convenient distance of Rochester, affording all the facilities of a large distributing center, and at the same time the freedom and spaciousness of a small town. The factory site comprises seven acres, conveniently located on the Northern Central R. R. At present there stand on it four buildings, of various sizes; but these have been so planned that more buildings can be added when desired without serious disturbance of the existing layout.

The main building is of brick, mill construction, 406 by 60 feet, and two stories in height. Its architecture has considerable distinction, given by the prominent buttresses between each of the large windows. In the center is a tower, projecting and carried to a slightly greater height than the body of the building. The lower floor of the building is devoted entirely to machine work, and each department has a separate motor for supplying the required power. The upper floor contains first the reception room and offices, reached from a private entrance at the front end of the building. Back of these are the designing and drafting rooms. The remainder of the floor is occupied by the final assembly room and the painting and upholstering shops. The upper floor has a full skylight roof, giving an abundance of light.

Convenient Arrangement of Small Buildings—At the left of the main building is a long, low frame structure for the accommodation of cars undergoing the road test. It will house nine cars, as may be seen from the nine wide doors on its front. The cars may be driven directly in and out, without maneuvering. Five of the stalls have pits, over which the cars may be run for making adjustments. A large room, equipped with a complete lavatory, is set apart for the testing crew.

The heating plant, an isolated building of concrete block, is set near the far end of the main building. Its location, near the railroad, allows coal to be dumped direct from the railroad cars into the capacious fuel storage bins.

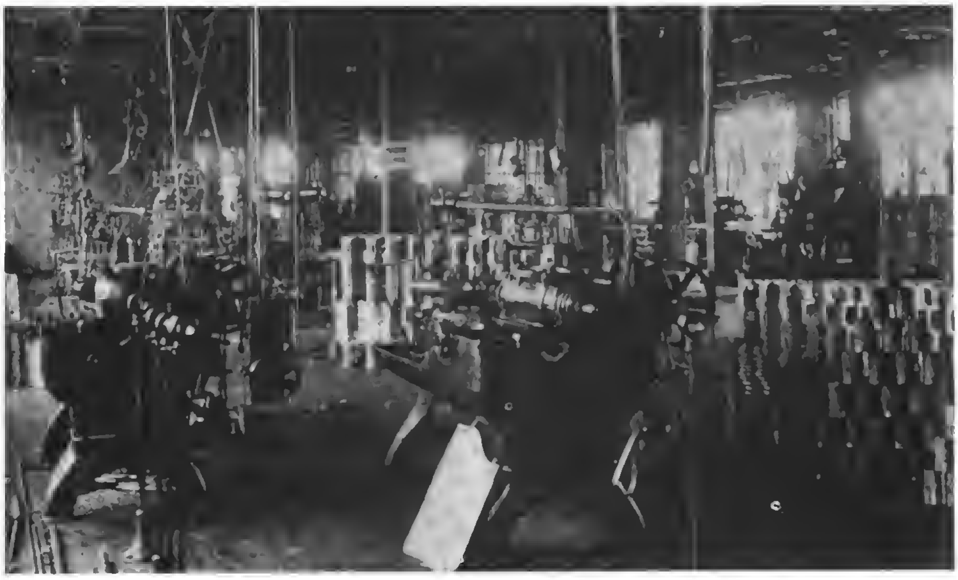
Just beyond this is located the blacksmith shop. All work of this kind is thus done at a sufficient distance from the main building, relieving the shops of the noise and dirt inseparable from blacksmithing. Such precautions, reacting in the contentment of the employees, are becoming a feature of factory design.

Paint Shop, with Bodies in Various Stages of Finish

Up-to-Date Tools in Machine Shop—The machinery equipment is the best obtainable, all new within the past three years. The photograph showing a part of the machine shop reveals many interesting details of practice. In the foreground may be seen two automatics, one working on pistons and the other on gearshafts. No better example could be asked of the wide range of uses to which these handy machines can be put. Although similar in all important features, one is operating on iron castings 4 1-2 inches in diameter, varied in shape, and the other on 1 1-2 inch round steel bars.

At the right of the photograph is a stack of twenty or more unfinished pistons, waiting their turn on the automatic machine; in the corner stands a smaller pile of the finished product. Near at hand is a row of sixteen or eighteen cylinder castings. In the middle distance a number of the combined crankcases and gearboxes which distinguish the Mora design are standing on end, awaiting their turn to be bored. This operation, being performed simultaneously on the bearings of the crankshaft and the gearshafts, insures their cor-

Testing Garage, Where the Cars Undergoing the Road Test Are Sheltered rect and permanent alignment. The background will reveal upon study several drill-presses and a stack of crankcase upper halves. This view, of course, shows but one end of the machine shop; it should suffice, however, to give still further evidence of the quality of the tools. In this department, above all, up-to-date equipment amply repays its expense.



One Corner of the Busy Machine Shop—Automatic Lathes in Foreground

The comfort of the employees is assured by an abundance of light and ample room around the individual machines. The central tower, besides stairways and elevators, contains the lavatories for the shop hands.

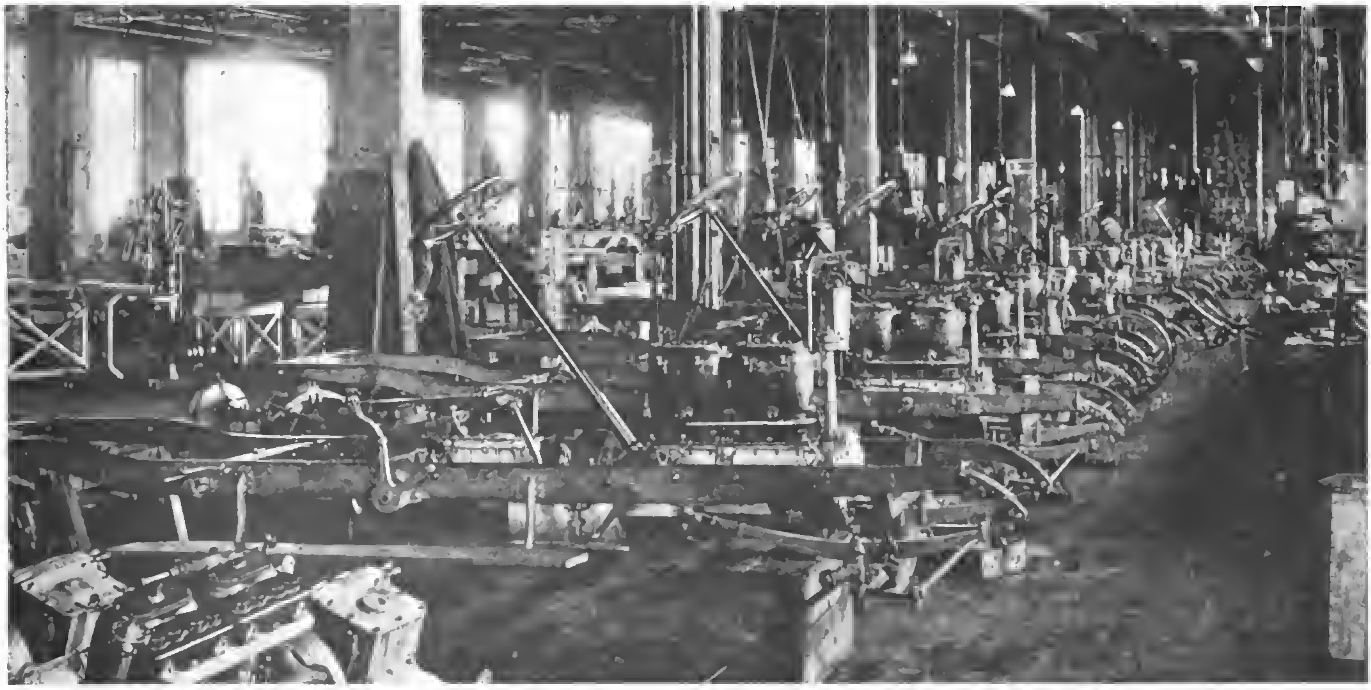
Attention Is Given to Testing—The country immediately surrounding the factory is one of steep hills and roads often rough. Altogether it is hardly a paradise for private touring, but offers just the conditions desired for a thorough testing of the Mora chassis. Before each car is turned over to the finishing department it must have shown a satisfactory performance on 250 miles of road work. The building in which the cars are housed during the testing process has already been described. It may be added, however, that automatic ventilators are provided to furnish fresh air and carry off the dangerous gases from the inspection pits.

After the testing the cars are cleaned by a steam blast, which is much more satisfactory than washing the metal parts. The blast also removes all oil and grease, giving a clean surface for the finishing coats of paint on the running gear. The paint shop, with a number of bodies, is shown in one of the photographs. These bodies are brought to the factory in the white; all painting and upholstering is done in the Mora shops. At the rear of the paint shop is the varnish room; one body may be seen on a truck in transit from one department to the other.

When the cars have been assembled, tested, fitted with bodies, and given their final inspection, they are ready to be shipped. For this purpose a sidetrack at the factory is imperative, as the cars must be loaded with care to avoid injury to their finish, and must be securely blocked and braced to prevent their breaking loose en route. The Mora factory, as mentioned above, is located on the Northern Central Railroad, connecting with the New York Central system at Rochester. The factory sidetrack accommodates fifteen box cars, and is graded down to bring the floors of the cars on a level with the lower floor of the building.

There is opportunity for some writer of proverbs in the relation between the factory and its product. It is nearly always the case that the company which insists on abundance of light and room in its factory will embody similar features in the car, which will then be generously designed, with a logical arrangement of parts and the utmost accessibility.

In conclusion, consideration will reveal that due attention has been given the three principles which govern factory design, namely, the proportioning of the individual buildings to secure the best light and greatest efficiency of the floor space; the arrangement of the various departments to eliminate all unnecessary haulage, and, finally, a due regard for the requirements of the future, with its natural expectation of growth.



Lengthwise View of Light and Airy Assembling Floor Reveals a Number of Chassis Nearing Completion

AUTO FIRE SERVICE WAGONS MEETING WITH MUCH FAVOR

WHEN the importance of fighting fires quickly is granted, as is done by everyone familiar with the situation, the necessity for the motor-driven, or as it is usually called, automobile fire wagon is conceded in the same breath. The reason for this is the inability of any animal to serve with the unerring precision of a machine. So, too, disease, illness, and other things enter to make the horse singularly unfitted to this use. Statistics show that the fire loss is $200,000,000 per year.

Combination Chemical and Hose Wagon for Bristol, Conn., Fire Department

How much of this is due to the use of inefficient horse-drawn apparatus no one can fully estimate, but it must be a very large percentage. To save this money, a number of prominent firms are turning to the construction of self-propelled fire apparatus. Among those who have been connected with this business for some time, and have, consequently, acquired a good working knowledge of the conditions to be met therein, is the Pope Manufacturing Company, Hartford, Conn.

The piece of apparatus shown on this page is a sample of the work done, being a wagon supplied to the town of Bristol, Conn. Many of the New England towns have gone in strongly for this type of wagon, Taunton, Worcester, Lowell, and Fall River each possessing one like that shown, while the latter city has a chief's wagon of the same make in addition.

It is called a combination chemical and hose wagon, being equipped with a 40-gallon tank, with full equipment, including 250 feet of 3-4-inch hose for the same. Then the central part of the body has space for 1,000 feet of 2 1-2-inch hose. Two 15-foot extension ladders, two hand extinguishers, and numerous axes, picks, lanterns, and door jimmies complete the fire-fighting means. The running board will accommodate from five to fifteen men according to the body design and the length of wheelbase.

On the car shown the wheelbase was 130 inches, standard tread, 30-horsepower engine, three-speed transmission, shaft drive, efficient brakes, gearing for 40 miles per hour, and other parts of the regular Pope-Hartford chassis.

EVIDENCE OF TRUCK PROGRESS IN 10-TON MACHINE'S WORK

IN the table below is given the daily record of a ten-ton Hewitt truck, hauling coal in New York City, for two weeks in the month of October, just passed. This work was done in the service of Burns Brothers, a very large coal handling firm, whose work is evidently divided so that the truck made large hauls only to substations, about ten in number, from which places it was rehandled by smaller capacity wagons.

Prominent in this tabular study of the regular daily work of the largest truck in America is the unusually high ton-mileage. Specially fitted touring cars competed in many contests, but very few of them—they may be counted on the fingers of one hand—ever exceeded the figures attained by this coal-hauling monster. The average daily mileage of 35.4, taken together with the average daily tonnage of 84.03, and weight of the truck itself, give the astounding figure of 34.43 ton-miles per gallon of gasoline.

From the table the following very interesting figures have been compiled, these being figures which relate to the work done and the efficiency of the machine in doing it only:

Average miles per day	35.4
" gallons gasolene per day	11.9
" miles per gallon	2.97
Total tons in 13 days	1,092.39
Cost per day (maximum)	$16.00
" " ton	$ .19
Average miles from base	2.13
Weight of car, empty	13,000 lbs.
Average weight of load	20,250 "
Total weight	33,250 "
Average ton miles per gallon of gasolene	34.43

BOSTON TRADE PREPARATIONS FOR A BUSY NEW YEAR

BOSTON, Dec. 6—The establishment of new agencies and changes in location of old ones have been quite numerous of late in Boston, and others seem likely to occur in the not distant future. The expansion of the automobile trade in the vicinity of Massachusetts avenue will be aided by the completion of the new garage at the corner of Massachusetts avenue and Newbury street. The property was purchased by F. J. Tyler, of the Maxwell-Briscoe Boston Company, some months ago, and has been completely remodeled, the upper floors being equipped for garage and repair shop purposes and the street floor being used for salesrooms. The store at the corner of the avenue and Newbury street already is occupied by the Maxwell-Briscoe Boston Company as a salesroom, and one of the other stores has been taken by the Austin Company, the new agency for the Austin car. Other automobile agencies are considering renting the other stores.

A new arrival on Massachusetts avenue is the Henderson-Lowe Company, of which the veteran "Pop" Lowe is manager, and which has opened an agency for the Midland car at 117 Massachusetts avenue, the salesroom once occupied by the Dragon branch and later by the Grout agency.

Along Boylston street there are a number of changes, the most prominent being the erection of the new Goodrich tire building that will be ready for occupancy in a few weeks. The Goodrich branch is now on Columbus avenue. The Selden agency has taken a new salesroom at the corner of Boylston street and Fairfield street, and just around the corner on Fairfield street there was opened a few days ago the new Palmer-Singer agency. Copley Square, one of the finest squares in the city, has been invaded by the motor car trade.

For a long time the Locomobile branch was alone in Copley square, but this fall the American Motor Car Company, agent for the American, opened a salesroom there and this week the Rainier Company of New England, of which Raymond S. Joo is manager, has moved to a store alongside the Locomobile branch, from its former quarters in the Motor Mart. H. C. & C. D. Castle, of Boylston street, agents for the Lozier, have added the Haynes to their line. On Huntington avenue a new agency is W. L. Russell & Co., handling the Apperson car.

While there is a tendency to move away from Columbus avenue toward Boylston street, there are a number of new agencies in the older section. The Croxton-Keeton Motor Car Company, of which L. F. Witherell is manager, has opened a salesroom in the Motor Mart for the Croxton-Keeton car and the Hub Automobile and Renting Company has taken the agencies for the Pullman, formerly held by the Crown Motor Car Company of the Motor Mart, and for the Black Crow. The Overland agency, managed by Charles Andrews, formerly of the J. M. Linscott Co., has its headquarters at 24 Columbus avenue, and the Thomas branch is located in upper Columbus avenue, until better quarters are obtained.

The Corlew-Coughlin Co., agents for the Velie, has just rebuilt the large building at 21 Hawkins street and opened it as a down-town garage, while the S. M. Supplies Co., has added the Empire car to its list. The first aeroplane agency in Boston has been opened by J. H. MacAlman on Boylston street.

DETROIT'S SHOW WILL BE NOTABLE

DETROIT, Dec. 6—When it came to allotting space for exhibitors at the Detroit Auto Dealers' Association show, to be held at the Wayne Hotel Gardens January 24-29 next, the committee having the matter in charge found itself up against the serious problem of cutting demands down to meet the available space, a task not easy when more than 36,000 square feet was asked for with a trifle over 31,000 available.

TWENTY-SIX WILL MAKE THEIR DEBUT

Detroit's show will have 191 models of 58 different makes. Twenty-six of the makes are to be exhibited locally this year for the first time and of this number fifteen are the product of companies which have come into existence since the last show, all being local. As several prospective exhibitors are still to be heard from, the committee reserved the right to alter allotments in the event of further entries.

MASSACHUSETTS SUPPLIES SOME REAL STATISTICS

BOSTON, Dec. 6—Figures of the automobile department of the Massachusetts Highway Commission for the fiscal year ending November 30 have just been compiled, and they show for the twelve months included in the calculation a tremendous increase in every department of motoring over the preceding year. Receipts from motorists for registration certificates, licenses, etc., increased about forty per cent. and the registration of cars increased approximately thirty per cent. The total receipts during the past year of the automobile department were $169,973.54 against $121,488.50 last year and $92,091.50 in 1907. The total number of cars registered during the year ending November 30 was 23,902, while in the preceding year the number was 18,052. The registration of motor-cycles numbered 2,392 against 1,917 the year before. The growth of the trade is indicated by a gain of considerably more than one hundred in the number of manufacturers and dealers registered. Last year there were 379 and this year 491.

The issuance of licenses to drive, both to operators and chauffeurs, however, is the most striking evidence of the growing popularity of motoring. Two years ago 4,721 licenses were issued, last year 5,865 were added, and the total was increased this year by 8,336. There are now in effect approximately 35,000 licenses issued to private operators, all of which become invalid the first of next month when the new automobile law goes into effect. There has also been a surprising growth in the number of chauffeurs, and nearly 10,000 persons hold licenses entitling them to operate motor vehicles for hire, the exact number being 9,915. Last year there were 7,305.

Statistics of accidents in which motor cars were concerned have also been tabulated by the Highway Commission, and these show an alarming increase in the number of fatalities. The commission began keeping track of accidents in July, 1908, and for the five months ending November 30, 1908, there were 13 fatal accidents, which would be at the rate of 31 for the year. During the year ending November 30, 1909, there were no less than 54 fatalities. In August alone there were 11, almost as many as in five months of the previous year, and last month there were 10. Injuries caused by automobile accidents did not increase this year over last. In the five months of 1908 for which there are records, 486 injuries were reported to the commission, which, if the injuries were distributed evenly throughout the year, would make a total of 1,166 for 1908. This year the total number of injuries in motor car accidents reported to the commission was 969.

PRESERVING THE EQUILIBRIUM

Prosperity carries many a man off his feet; adversity compels him to move with deliberation. Business corporations are managed by human beings, and consequently they are subject to the same tests as are supplied to the individual. The automobile industry is plainly at flood-tide, and there is bound to be a considerable amount of flotsam and jetsam afloat. It has been an inevitable happening in every new industry, to reach a period of over-production; and an over-production in this industry, involving millions of dollars, would mean incalculable harm to all producers and sellers concerned in one way or another.

While there is no excuse whatever for timidity, there yet remain logical reasons why preparations for the future demand should receive a careful survey, especially by concerns recently launched or about to be introduced into a new and somewhat problematical field. Prosperity is evident, but the depth of it should be examined with due regard to a future which naturally will not offer as promising a prospect as the present heyday of active demand and a temporarily inadequate supply.

'Tis the wise man who looks farther ahead than a twelve-month; and the making of automobiles and accessories does not belong in the list of "get-rich-quick" undertakings. Methods which may seem applicable to one industry are a misfit in other channels; and there are a few misfits in the business of producing automobiles.

ADVANTAGES OF WORM DRIVE

American engineers might profitably give some thought to the tendency of English automobile design, as revealed by the Olympia show, toward worm drive. The worm and its gear, in this construction, replace the usual bevel gear and pinion on the rear axle. Although confined two years ago to a single maker, this drive is now employed by half a dozen English firms of the highest repute. Its adoption seems to have been solely on its merits, due to the advantages which it possesses over the bevel drive for certain classes of work.

The most common, and most erroneous, objection to the worm gear as a means of final drive is the superstition that it is irreversible; that is, that it would be impossible to push a worm-driven car by hand, say on the garage floor. This fallacy is derived from the use of worm gears in the steering gear. As a matter of cold fact, the reversibility or irreversibility of a worm gear depends on the angle of its thread. A "slow" worm, such as is used in steering gears, may be irreversible; but a "quick" worm, in which the threads may be at 45 or 60 degrees from the axis, reverses perfectly.

Of greater actual weight is the contention that the worm is inefficient as a power transmitter. The advocate of the worm can afford, however, to yield considerable ground on this point without endangering his case—as we will show later. However, the truth is that the only published tests of worm gears were made before the day of modern ball-bearings and gear-cutting machinery, and form a poor basis for argument.

The worm really only competes with the bevel in the case of low-powered runabouts and heavy trucks—both cases in which a considerable gear reduction is demanded between the motor and the wheels. In a bevel gear the reduction is the ratio of the diameters of the gear and the pinion; to secure a large reduction, either the gear must be big or the pinion little. Structural considerations interferes on one side, and lowered efficiency and shortened life on the other. The gear reduction of the worm, however, depends on the pitch as well as on the size; indeed, a considerable range of ratios may be had with the same-sized worm and gear.

The use of the worm drive on runabouts and commercial cars, therefore, allows the necessary reduction to be obtained in a simple and compact piece of mechanism. The efficiency, moreover, is at least as good as that of a bevel set with the exaggerated dimensions necessary for the same work, or of any form of double reduction by spur gears and bevels, or bevels and chains. The bevel gear, it must be remembered, is itself by no means remarkable for efficiency. In combination with another form of gearing, the efficiency of the set could not well exceed 90 per cent. That figure is easily attainable by a properly cut and lubricated worm with ball thrust bearings; in fact, tests made as long ago as 1898 showed an efficiency of 92 per cent.

Still another consideration. In a worm set, the axis of the driving shaft does not intersect the axis of the driven shaft, but is at a distance from it which, in automobile practice, might be from four to six inches. If the worm is above the gear, the engine can be set high to obtain a good clearance, and the drive shaft joints will normally work in a straight line. Thus one may kill with a single stone not only two, but even three, birds.

EXHIBITORS FOR GARDEN'S TENTH NATIONAL SHOW

THAT the Tenth National Automobile Show in Madison Square Garden, January 8-15, will eclipse any former similar exhibition ever held in the famous building is positively assured by the official list of exhibitors just issued by the Association of Licensed Automobile Manufacturers under whose auspices the show is held. The list shows a total of 323 different displays, of which there are 54 exhibits of complete cars, besides 246 exhibits of accessories and parts, and 23 motorcycle exhibits.

Even with an increase over last year of more than 7,000 feet of exhibition space, which the show managers by ingenious methods were able to squeeze out of the Garden interior, there is not one foot of space available for exhibition purposes to be had in any part of the building at present and there is a long waiting list.

The list of exhibitors, with the number of their spaces, follows:

MAIN FLOOR

1 Elmore Mfg. Co.
2 Everitt-Metzger-Flanders Co.
3 Studebaker Automobile Co.
4 F. B. Stearns Co.
5 Knox Automobile Co.
6 Columbia Motor Car Co.
7 Autocar Co.
8 Corbin Motor Vehicle Corp.
9 Matheson Motor Car Co.
10 The Pope Mfg. Co.
11 Lozier Motor Co.
12 Locomobile Co. of America.
13 American Locomotive Co.
14 Packard Motor Car Co.
15 Pierce-Arrow Motor Car Co.
16 Cadillac Motor Car Co.
17 Chalmers-Detroit Motor Co.
18 E. R. Thomas Motor Co.
19 H. H. Franklin Mfg. Co.
20 Winton Motor Carriage Co.
21 Stevens-Duryea Co.
22 Peerless Motor Car Co.
23 Buick Motor Co.

ELEVATED PLATFORM

24 Selden Motor Vehicle Co.
25 The Willys-Overland Co.
26 Hewitt Motor Co.
27 Royal Tourist Car Co.
28 Mercer Auto Co.
29 Olds Motor Works
30 Haynes Automobile Co.
31 Waltham Mfg. Co.
32 Hudson Motor Car Co.
33 Apperson Bros. Auto. Co.

EXHIBITION HALL, MADISON SQUARE FRONT

50 Woods Motor Vehicle Co.
51 S. R. Bailey & Co., Inc.
52 The Waverly Co.
53 Babcock Electric Carriage Co.
54 Columbia Motor Car Co.
55 The Baker Motor Vehicle Co.
56 The Anderson Carriage Co.
57 The Rauch & Lang Carriage Co.
58 Studebaker Automobile Co.

BASEMENT, COMMERCIAL VEHICLE DEPARTMENT

75 Knox Automobile Co.
76 E. R. Thomas Motor Co.
77 Studebaker Automobile Co.
78 Baker Motor Vehicle Co.
79 H. H. Franklin Mfg. Co.
80 American Locomotive Co.
81 The Autocar Company.
82 General Vehicle Co.
83 Packard Motor Car Co.
84 The Pope Mfg. Co.
85 Alden Sampson Mfg. Co.
86 Hewitt Motor Co.

ELEVATED PLATFORM, ACCESSORIES

100 The B. F. Goodrich Co.
101 The Diamond Rubber Co.
102 C. F. Splitdorf.

619 Emblem Mfg. Co.
620 Marvel Motorcycle Co.
621 Reliance Motorcycle Co.
622 S. D. Mfg. Co.

REEVES TO BE A.L.A.M. MANAGER?

Detroit, Dec. 6—It was learned here to-day that Alfred Reeves, of New York, has been tendered the position of general manager of the Association of Licensed Automobile Manufacturers which carries with it a salary of $15,000 a year. Rumors to this effect got into circulation here soon after the decision of the Selden patent suit, but now it can be stated definitely that the offer has been made.

Mr. Reeves for the past four years has been general manager of the American Motor Car Manufacturers' Association, which has opposed the licensed makers, but since the practical settlement of the patent controversy many of the independent makers have joined the A.L.A.M., or secured licenses, and others are expected to follow.

The annual Grand Central Palace show in New York is managed by Mr. Reeves, but following that affair it is believed he will assume his duties wtih the licensed association, provided he decides to accept the tender that has been made.

When seen in New York Tuesday Mr. Reeves asked to be excused from making any statement regarding the above report from Detroit. He would not deny that an offer had been made, but insisted that he would be manager of his present association for some time to come.

SOME GOSSIP FROM MOTORDOM'S HUB

Detroit, Dec. 6—This "Hub of Motordom" frequently sees many faces from "dear old Broadway." Pretty nearly every New York paper last week had its representative in the field looking for show business. The advertising managers of the factories loaned them cars to get around the vast district in as quick time as possible, presumably that the sooner they helped their New York visitors to get out of town, the sooner they would again be able to settle down to work.

E. LeRoy Pelletier, advertising manager of the Studebaker factories, was forced to undergo an operation for trouble with his nose, and spent the week in the hands of doctors.

When "Jack" Lasley was in town he saw Lee Counselman, sales manager of the Chalmers-Detroit Motor Company. Mr. Lasley, as agent of the Eclipse bicycles at Washington, gave Mr. Counselman his first living wage, $25 a week. Mr. Counselman became an amateur (?) star on the Eclipse team and gained renown in that field. Mr. Lasley owned a cash register business, and into that field the young bicycle rider grew naturally, graduating to the National Cash Register Company, where he became a right-hand man for Hugh Chalmers, who took him into the automobile field.

E. Ralph Estep, advertising manager of the Packard Motor Car Company, has a show place in his photograph gallery, of which he is very proud. This department is fitted up regardless of cost, the entire outfit being perhaps the best in the world for the exclusive use of one concern.

George Banker, looking fine as a fiddle and quite like the George Banker of the days of cycling when he ranked as a champion in America and Europe, was a Detroit visitor recently. George and his brother, Arthur, are making the Banker Brothers Wind Shield Company boom. "It is night and day work for us right along," said he.

M. & A. M. ADDS TO MEMBERSHIP

At the meeting of the board of directors of the Motor & Accessory Manufacturers, held in New York City, November 27, a number of companies well known in trade circles were elected to membership. The additions are the Auto Parts Manufacturing Company, the Batavia Rubber Company, the Driggs-Seabury Ordnance Corporation, the Excelsior Motor & Manufacturing Company, the Havoline Oil Company, the Royal Equipment Company, the Seamless Rubber Company, the Warner Manufacturing Company and the Thermoid Rubber Company.

THE HOTEL BRESLIN'S AUTO SHOW

There must be such a thing as luck, according to the belief of those who attended the annual show luncheon given to the trade by Manager W. E. Hildredth of the Hotel Breslin, held Monday noon in the grill room of that popular Broadway hostelry. H. C. Esselsteyn first drew for the R. M. Owen Company in connection with the Grand Central Palace show, the result being that the Premier secured the exhibition privilege of the Breslin lobby during the show period. Next, Mr. Esselsteyn drew for Carl H. Page Company, and again he secured the ticket marked "winner," which means that the Chalmers-Detroit will occupy the Breslin pedestal during the Madison Square Garden show. Henry M. Duncan was the graceful toastmaster of the occasion, and the other talkers included Host Hildredth, and M. L. Downs of the A. L. A. M. show and Alfred Reeves, general manager of the A. M. C. M. A. Besides the contingent at the star table, which included James C. Young, secretary of the Madison Square Garden Company, the list of those present included the following: John Plummer, Locomobile Company; J. M. Boyle, Midland Car Company; W. J. Donlan, Studebaker Car Company; William M. Haradon, Columbia Car; Keene Carruthers, Mitchell Car Company; C. A. Benton, Sultan Motor Company; P. F. Rockett, Isotta Import Company; Philip H. Lucas, Reo Car; H. C. Esselsteyn, Premier Car; W. McK. White; William L. Colt, Colt-Stratton Company; Julius Augustine, Franklin Car; J. S. Norton; O. Frost, Black Manufacturing Company; Capt. H. L. Stratton, Colt-Stratton Company; J. R. Flanagan, Pullman Car; Charles M. Brown, Winton Car; William E. Adams, H. J. Koehler Company; Frank Eveland, Stevens-Duryea; A. J. Stocker, of Frank Presbury & Co.; A. N. Jervis, of American Locomobile Company; A. G. Batchelder, N. Lazarnick, E. F. Korbel, R. B. Johnston and Ernest Crowhurst.

BUFFALO SHOW SITUATION SETTLED

Buffalo, Dec. 4—The Eighth Annual Automobile Show will be held in the Broadway Arsenal, February 14-19, under the direction of the Buffalo Automobile Trade Association. It will have the co-operation of the Automobile Club of Buffalo, but it is announced that the Trade Association will manage the show. This ends a struggle between the club and the association as to which should conduct that enterprise this year.

The Trade Association announced last year that the show of 1909 would be the last to be run by the club, and that thereafter the association would manage those affairs. Various propositions to smooth over the difficulties between the two bodies were brought forward from time to time, but the Trade Association rejected them and declared that if the club held a show in the Broadway Arsenal, the association would hold another in Convention Hall. Finally, the club agreed to take $2,500 as its share of the enterprise and in return for its co-operation, leaving the association to run the show.

G. L. Poppenberg and Charles F. Monroe, and Laurens Enos and Harry T. Vars, two from each organization, will constitute the advisory committee in charge of the show; but the Trade Association will run the enterprise through committees in charge of every detail.

AMERICAN PRODUCT OPENS GERMAN EYES

Henry Hess, president of the Hess-Bright Manufacturing Company, Philadelphia, is making the rounds of the automobile industry, accompanying Director General Kosegarten and Chief Engineer Gohlke of the D. W. F. Ball Bearing Company, of Germany. When the representative of The Automobile interviewed the party at Indianapolis, Buffalo, Cleveland, and Detroit, the foreign visitors admitted that they had been impressed with the vastness of the industry. In many places the rate at which automobiles were being turned out proved to be perfectly astounding, although Director General Kosegarten, of the D. W. F., himself is the head of a concern of no mean proportions.

N. H. Stewart Drives Franklin Six, Winner in Kalamazoo, Mich., Parade

On the occasion of the floral parade commemorating Kalamazoo's silver anniversary, Mr. Stewart's 42-horsepower Franklin took first prize. The car was a mass of purple flowers with a white background. The occupants, beside Mr. Stewart, are Mrs. E. R. Burdict, Mrs. Donald Stewart, and Misses Irene Taylor, Lillie Speyer, Eleanor Austin and Elsa Speyer

Grossman Prizes for Dealers—On Thanksgiving Day the Emil Grossman Company announced a number of cash prizes for dealers who handle its line of accessories. Eighteen prizes will go to the houses whose catalogues embrace the best representations of "Red Head" spark plugs, "Red Rib" cable, Peugeot chains and the Grossman line of wind shields, bumpers, etc. Twelve prizes will be given for newspaper and theater program advertisements, six for window displays during the holiday season and twelve for show window and store displays between January 1 and July 1, 1910. An editor of a leading automobile publication and two general advertising men will be the judges of all contests. Cartons for show window displays, hangers, card and electrotypes will be furnished gratis to all who desire to participate.

Open Season for Tire Advice—If amateur drivers who lay up their cars for the winter find the tires in bad shape next spring, it will not be for lack of good advice. The Firestone Company is the latest, as follows: "If an owner is bound to store his car without removing the tires, it is best to jack the wheels up off the floor and let out some of the air, as well as seeing that the tires are clean and free from oil. The best way, however, is to remove the tires from the wheels. The tubes should be taken out, cleaned, painted with graphite, wrapped up and put away in a dark place where the temperature is always about 30 deg."

Favors a Contest of Tires—Howard E. Coffin, chairman of the contest board of the Manufacturers' Association, endorses the suggestion of the B. F. Goodrich Company that future endurance runs should include competitions for tires, and will attempt to have rules for this purpose formulated by the board. It is probable that carbureters, magnetos and other accessories will receive similar attention. Makers of accessories who interest themselves in touring contests for these honors will be made parties to an agreement to advertise only the real facts.

New Car From Badger State—The Wisconsin Carriage Company, of Janesville, Wis., has started work on a series of 100 touring cars for the 1910 market. Specifications include a four-cylinder 4 3-8 by 4 3-4 motor; Schebler carbureter; Bosch magneto and battery; cone clutch; three-speed selective ball-bearing gear; full-floating rear axle with enclosed drive shaft, also ball-bearing; 115-inch wheelbase and 34-inch wheels, selling at $1,750, with either touring or baby tonneau body. T. E. Warnock is designer and Oliver Gleason shop superintendent.

Minnesotan Company Reorganized—The reorganization bug has penetrated far from its usual haunts, even unto peaceful Minneapolis, Minn. There the H. E. Wilcox Motor Company has increased its capital to $1,000,000, and proposes to make 300 touring cars and 150 trucks. H. E. Wilcox is president and manager, John F. Wilcox vice-president, G. W. Lewis treasurer, P. W. Strong, sales manager, and Claude E. Cox chief engineer. C. L. Wood will be chief engineer of the truck department.

Dynamometer for Moon Company—In order that each car which leaves the factory may be tested for full rated horsepower, the Moon Motor Car Company, of St. Louis, has decided to install a specially made dynamometer. Some device of this sort is recognized as necessary in a modern plant, if horsepower is to be determined in other than theoretical ways. The dynamometer was constructed under the direction of C. M. Garland, professor of engineering at the University of Illinois, and will be installed this week.

Boston Men to Make Trucks—A. L. Waugh, a dealer in commercial vehicles in Boston, is organizing with Frederick Wells and J. G. McDonald, a concern to be known as the United Vehicle Company, to manufacture a complete line of commercial cars from 1-2 to 5 tons capacity. The company plans to erect a concrete building with 80,000 square feet of floor space near the present Waugh salesroom and make 150 cars first year..

Concentrates on Wholesale End—The Motor Car Equipment Company has sold its uptown New York branch to the Lowe Motor Supplies Company and has permanently retired from the retail field. The company now occupies a six-story 25x100-foot building at 55 Warren street. Three floors are devoted to stock and one to packing exclusively. Fifty orders can be filled simultaneously.

Another Lecture on Electrics—An illustrated lecture on the care and operation of electric vehicle batteries was delivered in Washington Hall, Detroit, on December 6, by Bruce Ford, engineer of the Electric Storage Battery Company, of Philadelphia. The lecture was given under the auspices of the Edison Illuminating Company.

New Detroit Magneto-Maker—T. G. Baillie, M. Fletcher, E. M. Tyler, John A. Lotz and A. A. Fletcher have incorporated a new accessory manufacturing concern in Detroit under the name of the Detroit Magneto Company, with a capital of $100,000.

IN AND ABOUT THE AGENCIES

Baker, Cleveland—The Baker Motor Vehicle Company has acquired the corner of East Seventy-first street and Euclid avenue and will erect a new building with showrooms on the avenue side and a garage on Seventy-first street. One of the showrooms is to be occupied by the Standard Automobile Company, agent for the Packard.

Royal, Rochester and Syracuse, N. Y.—Hobart M. Adams, sales manager of the Royal Tourist Car Company, announces that the Schoeffel Auto and Livery Company has been appointed Royal agent in Rochester, N. Y., and that a sales company is being formed in Syracuse, N. Y.

Chalmers-Detroit and Thomas, San Francisco—The Pioneer Automobile Company, which handles the Chalmers-Detroit, Hudson, Thomas and Randolph, will remove shortly to temporary quarters on Golden Gate avenue, near Gough street, during the erection of its new building.

Rambler and Crawford, Philadelphia—The Hoopes Motor Company, Broad and Fairmount avenues, has succeeded the Crawford Automobile Company, of Philadelphia, and in addition to the Crawford the new concern has acquired the Philadelphia agency for the Rambler.

National, Atlanta, Ga.—J. J. and J. L. McLendon, under the name of the National Motor Sales Company, have been appointed Georgia agents for the National. On December 1 they moved into the former Maxwell salesrooms at 38 Auburn avenue.

Kline Kar, Baltimore—The Palace Motor Car Company, J. S. Ditch, president, and Edward T. Boswell, secretary and treasurer, has the Kline Kar agency for Maryland, and has opened a salesroom at Mount Royal and North ave.

Stearns, Baltimore—The McMullen-George Automobile Company will have the Maryland agency for the Stearns. It has the former Ford salesroom in the Academy of Music building, with garage and repair shop at 542 Tyson street.

Everitt, Philadelphia—The Wayne-Davis Automobile Company has been awarded the Philadelphia agency for the Everitt. The territory will include Eastern Pennsylvania, Del., Md. and Va.

Velie and Empire, Macon, Ga.—E. J. Willingham, Jr., and J. C. Wheeler have opened a large garage at Cotton avenue and Cherry street, Macon, and have the State agency for the Velie and Empire.

Velie, Mason and Fuller, Salina, Kan.—F. W. Reed and P. D. Miller will occupy the 50 by 100-foot building at 131 North Fifth street by February 1, and will handle the Velie, Mason and Fuller cars.

Marmon, Louisville, Ky.—The Atlas Machine Company, agent for the Empire in Louisville, has added to its line the Marmon and expects to open a new garage within the next few weeks.

Haynes, San Francisco—The Haynes Auto Sales Company, which was recently appointed local agent for the Haynes, has opened a salesroom on Golden Gate avenue, near Van Ness.

Studebaker, Durant, Okla.—The Durant Motor Company, of Durant, Okla., has been appointed agent for the Studebaker lines, and will control four adjacent counties.

Apperson, Boston—W. L. Russell & Company, who are the agents in Boston and vicinity for the Apperson, have opened at 169 Huntington avenue.

Midland, Kansas City, Mo.—The Midland Motor Car Company branch in this city has removed to new quarters at 1523 Grand ave., where it has a fine place.

Moon, Houston, Tex.—The Auto and Motor Boat Company has been appointed local agent for the Moon car, made by the Moon Motor Car Co., of St. Louis.

Schebler Carbureters, Detroit—Wheeler & Schebler, of Indianapolis, have opened a Detroit office at 876 Woodward avenue, in charge of L. M. Railsback.

Paterson, Philadelphia—The Penn Automobile Company, 4212-18 Chestnut street, has taken the Philadelphia agency for the Paterson, made in Detroit.

PERSONAL TRADE MENTION

Charles B. Shanks, formerly sales manager of the Winton Motor Carriage Company and later occupying the same position with the F. B. Stearns Company, Cleveland, was in New York City last week and visited old friends along "Automobile Row" in upper Broadway. Mr. Shanks is now connected with the Jacobs-Stine Company, the largest real estate operators on the Pacific coast, with headquarters at Portland, Ore. Before finally starting westward, Mr. Shanks paid a visit to the Croxton-Keeton factory at Massillon, Ohio, and ordered one of the 1910 models for his personal use. The former hustling sales manager admitted that he was meeting with as much success in selling real estate as he did in the past in disposing of motor-driven vehicles.

Chas. B. Shanks

W. E. Metzger, of Detroit, Mich., wears a rather expansive smile these days, occasioned by the definite knowledge that he is once more firmly and securely in the A. L. A. M. fold. Though the official announcement is delayed for a well-understood reason, it is nevertheless a fact that the new company of which Mr. Metzger is the head has secured a transfer of the license of the Hewitt Motor Company of New York City. This means that Metzger cars will soon be forthcoming with the A. L. A. M. stamp of approval.

Wm. E. Metzger

George W. Hipple, formerly of the Levy-Hipple Motor Company, of Chicago, is managing the Chalmers Motor Company, Philadelphia agents for the Chalmers-Detroit. Frank Fanning, head of the Chalmers-Fanning Company, former representatives of the car in the Quaker City, is now Philadelphia agent for the Mercer.

W. R. Darrah, long and favorably known in the old bicycle days as the Barnes "White Flyer" agent in the Quaker City, has joined the sales force of the Studebaker branch in Philadelphia.

C. J. Welch, formerly with the E. R. Thomas Motor Company, Buffalo, N. Y., has been appointed sales manager of the Inter-State Automobile Co., Muncie, Ind.

Louis C. Block, manager of the Philadelphia Ford branch, is in Cincinnati launching a similar institution. He also opened the Buffalo branch.

O. P. Bernhart, vice-president of the Croxton-Keeton Motor Company, is on a trip through the West in the interests of the company.

Another German Tire Represented Here—In the opening of an office and salesroom at 1693 Broadway by the Calmon Asbestos and Rubber Works of America, Inc., last week, there was established an American selling agency for the well-known Calmon tires, made in Hamburg, Germany.

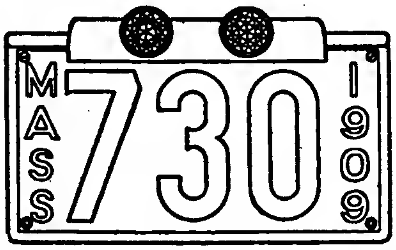
While Calmon tires are a more expensive product than most any tire sold in this country, this fact will amount to but little if the half of what the enthusiastic American sales agents claim for them is true. For instance, they have any number of letters and affidavits showing that abroad Calmon tires have frequently been in constant use for over 17,000 miles. One affidavit from a big electrical company shows that four tires used on their motor cabs had been used for 9,413, 10,985, 10,007 and 11,240 miles of continuous service.

Calmon Tire, a German Newcomer

The tires are splendid examples of rubber manufacture, somewhat heavier as to thickness of the stock than some of the American tires.

Information for Auto Users

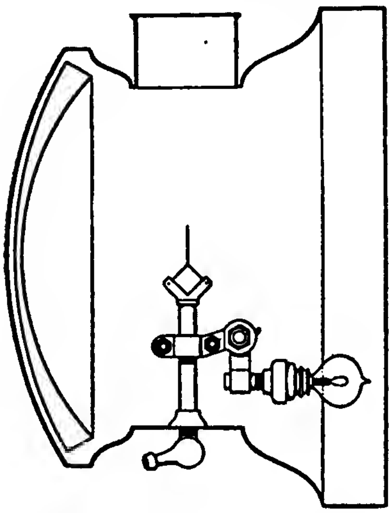
Gray & Davis Electric Attachments—The growing popularity of electricity as a means of lighting the car is evidenced by the action of Gray & Davis, of Ames-



G. & D. ELECTRIC TAIL-LIGHT AND NUMBER

bury, Mass., one of the best-known makers of gas and oil lamps, in bringing out a line of electric accessories. One of these is a tail-light, combined with a rear number plate, much like others that have recently been described in these columns. This lamp has two bulbs, so that if one gives out unexpectedly the rear of the car will not be left completely in the dark. These bulbs are six-volt and so may be used with the ordinary ignition battery. Means are provided for protecting the reflector by a glass door, and also for securing the bulbs so that they cannot be stolen. Patent on this device has been applied for.

Another device which opens up interesting possibilities is an electric attachment for acetylene headlights, so de-

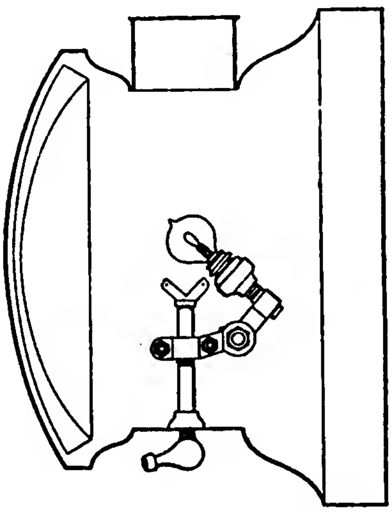


COMBINATION SEARCHLIGHT—GAS POSITION

signed that either gas or electricity can be used at will, with a minimum of exertion in making the change. The primary object of this device, as stated by the maker, is for use in cities where the full-powered gas light is undesirable. As is made plain by the drawings, the electric bulbs can be swung into or out of focus with a touch of the hand, after opening the door of the lamp.

Calmon Brake Lining—E. H. Garcin, of the Calmon Asbestos & Rubber Works, 1693 Broadway, New York, says of this material:

"Calmon Ajax brake lining is made of asbestos cloth specially woven for this



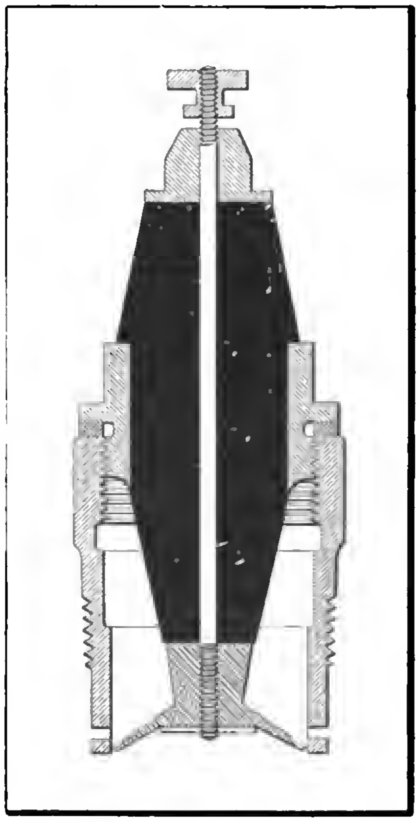
COMBINATION LIGHT—ELECTRIC POSITION

purpose. Each thread is spun around a wire center and the asbestos used is guaranteed to be 95 per cent. pure asbestos. The rubber compound coating used to thoroughly impregnate the material is cured under hydraulic pressure of more than 2,000 pounds to the square inch. This mode of preparation produces a lining that is water, oil, dust and grease proof that will not get hard, but which will grip instantly when it is needed.

"The care used in the spinning of the threads assures an absolute uniformity of their size so that the wear (or rather lack of wear) is equal in every portion of the lining."

New Multiple Point Spark Plug—In response to the demand for a spark plug the E. M. Benford Co., of Mt. Vernon, N. Y., has just placed upon the market a new magneto plug which is the result of several years' experimenting to produce one that will give better satisfaction, working with a magneto, than anything now on the market, and the results seem to justify their claim of a perfect or nearly perfect spark plug.

The construction is very unique. First an imported metal stamping with all the good qualities of platinum is set over a solid turned electrode. To hold this in place a cap of steel is placed upon same about ½ inch long. Then the mica tube is put upon the bolt after same has passed through an electrical heating furnace to burn out any vegetable matter that may be in the mica and to also thoroughly dry the mica. Carefully selected washers that have been passed through an electrical magnetic machine to test for iron are then placed over the tube, which is twice the thickness of the ordinary mica insulation. Over same is placed a brass bushing, which takes up any expansion in the metal part. Over the bushing more selected washers are placed and the entire plug is put under a pressure of 3,000 pounds in order to compress the mica into one homogeneous mass. After assembling, the plug is again placed in the electrical furnace in order to test whether any expansion will take place, and if so, it is again tightened up on the compressing machines. The plug is then turned in automatic lathes and assembled under the most experienced eyes. The particular features are the cone-shaped star, which prevents the oil from shooting into the chamber, and any carbon that should get by the cone-shaped star will find its way to the steel bushing, not to the mica, as in other plugs of this type.



NEW BENFORD SPARK-PLUG FOR MAGNETOS

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, DECEMBER 16, 1909—CHICAGO No. 25

THE AUTOMOBILE

INDIANAPOLIS SPEEDWAY IS READY

BY THOS. J. FAY

INDIANAPOLIS, IND., Dec. 14—With every brick laid except one, the Indianapolis Motor Speedway awaits its official reopening on Friday and Saturday of this week. This missing brick is a gold-plated one weighing 52 pounds and valued at $500. Of course it will be watched until the conclusion of the meet, after which its future resting place will be decided upon. Drivers of international repute will participate in the competition and time trials, and it is anticipated that many new records will be established during the two-day meet, provided the winter weather conditions are not unnecessarily severe. All who are connected with the enterprise are most enthusiastic and good records are promised.

The earlier speeding attempts on the Indianapolis track proved that after a certain velocity is attained, cars, unless they are almost unbreakable, will give way under work they are required to do, even when the road is better than the standard set for ordinary road building. On account of the unfortunate accidents that befell some of the racing automobiles during the opening meeting held at the speedway, which opened August 19 last, it was decided that nothing but the best possible pavement could be accepted, and the work of brick-paving has been under way ever since, culminating in the most perfect track possible to design and build, the dimensions being as in Fig. 1.

15-Ton Roller up 36 Degree Embankment

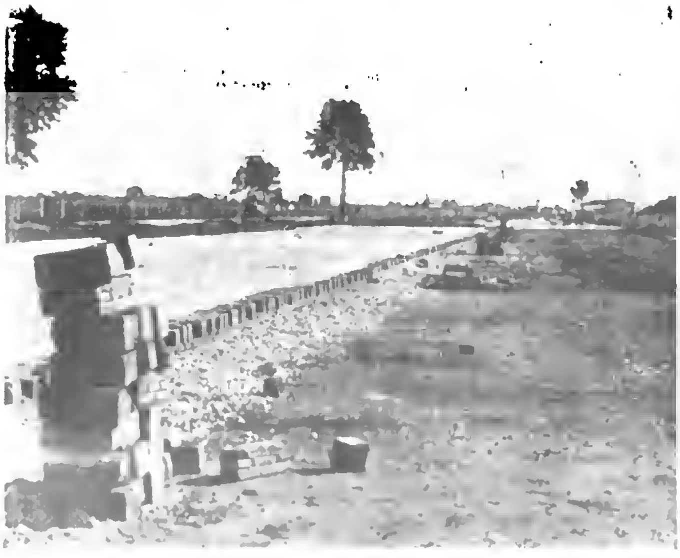
Belt Conveyor in Process of Laying Pavers.

Brick Pavement Finally Decided Upon—That the original track, so well constructed as it proved to be, will serve as a most capable "base fill" is conceded by all the road engineers who were consulted before the work of brick-paving was undertaken. The resurfacing, which was necessary, was well executed, as indicated in the statement here afforded as prepared by Park Taliaferro Andrews, holding the official position of chief engineer of the speedway. The engineer's resumé was gotten out by Mr. Andrews especially for THE AUTOMOBILE, and the author, having gone carefully over the whole work, is able to accept the engineer's resumé in the light of a most guarded statement of actual fact, to which nothing of value can be added.

The life of this brick-paved track, however, is as yet to be determined, and this phase of the problem, while it may be regarded as well looked into, must be to some extent considered within speculative confines and entitled to a little discussion at this time. That there is nothing new about brick may be readily shown; they were used in the Tower of Babel; about this time, so it is recorded, they were also made by the children of Israel, in Egypt, under the Pharaoh. To indicate, however, the uncertain history of this industry, it is only necessary to point out that pottery, which is akin to brick, was a product of cave-dwellers of the drift period from the Neolithic.

Crushed Surface Rock Ready to Spread on Old Track

Rolling Crushed Stone on Top of Old Track Surface



First Sample of Brick Surface Laid at Motor Speedway

Modern brick were first used, according to the most authentic sources of information, at Suffolk, in England, in the year 1260. In a hundred years from this time they were of fairly good manufacture, and in 1660 were in quite common use in London.

First Brick Kiln in America—At Salem, Mass., in 1629, the first brick kiln was probably established, although for many years nearly all brick used in this country came from Holland or England. Paving brick, which are of recent origin, were first used in this country in 1870, as nearly as present sources of information can be relied upon.

Process of Manufacture Defined—In the manufacture of paving brick there are many points to consider that do not have to be taken into account in connection with the manufacture of brick for building. From a suitable deposit of clay or shale the material is selected with the greatest care, crushed in dry pans or milled in solid rolls, they being about 48 inches in diameter and one foot wide. The rolls revolve within a revolving pan as much as 108 inches in diameter, the same being provided with a grated bottom. For a large-sized brick machine, two such pans are required, and the amount of shale crushed per hour lies between five and ten cubic yards; about two cubic yards of material is required per thousand of brick.

The crushed material is screened in a process involving fixed and shaking riddles, and knockers are employed to prevent the wet clay from sticking. From the screening process with its attending difficulties, which will not be discussed here, the clay goes to the "pugging" process, where the screened material is rendered plastic in form by suitable additions of water during the process of working in a properly contrived pug-mill. Pugging must be thoroughly done to remove air-enclosures, secure homogeneosity and reduce laminations to a minimum.

When the clay is well crushed, tempered and worked, which for the best results is frequently done by the wet-pan process, moulding follows. In moulding there is the "stiff-mould" process, which seems to be the more promising, despite frequent attempts to apply the dry-press system. A continuous working auger in the stiff-mud process forces the mud through forming dies, when the bar is sanded to prevent the brick from sticking together in the kilne. The bars, as they emerge from the forming dies, are cut to the required length, and a machine, under well-working conditions, is good for 100,000 bricks per day.

The repressing process, when it is applied, consists in putting freshly made stiff-mud brick into a die-box and subjecting it to a heavy vertical pressure, applied, as a rule, to the flat side. This process has the virtue of filling out the angles and edges, making the brick much more dense and uniform.

Drying is done by placing the brick on cars in a checkerwork fashion as high as possible within the sustaining ability of the stiff-mud condition of the brick to be dried, and the cars, so loaded, are run into drying chambers.

Burning, disregarding for the time the quality of material, is the most important process, for no matter how good the work may be done up to this process, No. 1 paving brick can only be the result of proper burning, and it is just here that the skill of the expert counts for everything. Burning usually takes place in from seven to ten days, and as to temperature, a shale brick requires from 1,500 to 2,000 degrees Fahrenheit, while brick made of fire clay demands from 1,800 to 2,300 degrees Fahrenheit.

Annealing follows, after the vitrifying temperature has been maintained for a sufficiently long time to heat the brick through to the center, which annealing is done by closing the kilns and allowing the brick to cool very slowly. For No. 1 brick, annealing should take from seven to ten days. Sorting follows after annealing, and in a properly processed batch of brick it is possible to realize fully 90 per cent. of No. 1 pavers. In this sorting, owing to many difficulties, mistakes are likely, and in the selection of paving brick for a job such as this, it is necessary to exercise the greatest care.

Engineers Had Many Difficulties to Guard Against—While the history of brick making is that of the human race, almost, even so, in view of the uncertainties involved, the selection and use of over 500 carloads of paving brick for this job represented a deal of painstaking labor, which involved divers precise detailed operations, some of which, however, was avoided, on this occasion, due to the care exercised in the earlier effort dating before it was decided to pave the course.

Methods Employed During the Whole Process—The course is two and one-half miles, being 50 feet wide on the straight stretches and 60 feet wide on the curves. The home-stretch and back-stretch 3,301 feet long, the end straights being 660 feet long, and each of the banked turns being 1,320 feet long on the course line. The curves are each 1-4 of a circle of 840 feet radius on the course line, or 90° of a 6° 49′ 30″ curve. No easement curves or spirals were used.

The curves are banked to an angle of 16° 40″ in cross-section for 50 feet of their width, the remaining 10 feet of width being banked to an angle of 36° 40″, all, as shown in Figs. 2 and 3. The approaches and releases to and from the banked curves are limited to a 2 per cent. grade in sections parallel with the measured course line, and the maximum variation from a level plane at the course line is a 2-10 per cent. grade. The straight stretches are given a pitch of 8-10 feet in 50 feet toward the infield for drainage, thus presenting a fine flat track for the cars.

Base Fill Was Thoroughly Rolled—With a 15-ton three-wheel steam roller the whole course was resurfaced and rerolled until the surface presented a smooth, firm and uniform plane. Two inches of creek gravel was then spread uniformly over the entire surface and rolled with the 15-ton roller. This was followed by a 2-inch layer of crushed limestone (rolled with 8-ton tandem roller), over which was poured two gallons of taroid to the square yard; this surface was then overcast with 1-2-inch crushed stone chips, filling the voids between the larger-size stone, and given another coat of taroid (of a lower melting point than the first coat), 8-10 gallon to the square yard being used in the second coat. Over this was spread a thin layer of crushed stone from 1-2-inch to dust in size, and given a final rolling with a 3-ton tandem steam roller.

This surface, which represented the original idea, did not prove to be satisfactory, and the idea of paving over this surface with brick is the matter with which we are now concerned. In proceeding with the brick paving it was decided to accept the No. 1 specifications of the National Paving Brick Manufacturers' Association, and 3,200,000 pressed paving brick were ordered from the Wabash Clay Company for the purpose.

The association, realizing the opportunity for a practical demonstration of brick as a paving material, has collaborated with the engineers of the speedway company, and has furnished two of its ablest men, viz.: W. T. Blackburn, of Paris, Ill., and C. G. Moore, of Cleveland, O. These men have acted as inspectors and advisory engineers.

The pavement has been carefully inspected as it progressed, every square yard of its surface being covered with a 12-foot straight edge, and any variation exceeding 3-8 inch in the 12-foot length removed before the grout was applied to the brick. Along each side of the straight stretches and around the inside of each curve a 5″ x 24″ concrete curb was placed, the top being flush with the surface of the pavement, and a 1″ expansion joint being provided between the pavement and the curb. No transverse expansion joints were used. At the outside of the pavement on each of the banked curves, and in front of the main grand stand, a 9-inch reinforced concrete wall 33 inches above the track surface has been built.

Two reinforced concrete bridges were built to support the track over a stream running diagonally across the southwest corner of the grounds. These bridges are 30 feet wide and 90 feet long, of a permanent character, located as shown in Fig. 1.

Drainage Regarded as Extremely Important—14.3 miles of tile have been laid to drain the grounds, the water which falls on the track being taken care of by a surface drainage system with flush gratings placed equidistant and three feet from the inside of the track. Agriculture drains have been used to care for the ground water.

Methods Employed in the Big Undertaking—The owners have conducted nearly all of the work themselves, only two contracts being entered into, one of which was rescinded owing to the contractor's failure to prosecute the work. The earth work, grading and forming the base fills, etc., was contracted by the C. C. King Bros. & Son Company, who used two outfits of the Western Elevating Grader drawn by traction engines, loading bottom-dump wagons.

As an auxiliary to these outfits, two gangs of wheeled scrapers were used, and between 2,000 and 3,000 yards of average cut and fill was moved daily by this means, the contractors completing their work within the time limit of 60 days in a satisfactory manner. A contract was also entered into for a portion of the brick paving, but the owners were forced to rescind and prosecute the work themselves.

Over 500 carloads of brick were required for paving and in the cement filler between the brick, and the concrete work incident to the track over 80 carloads of cement were used, 53 being used for the grout filler in the brick pavement alone. The entire brick paving of the track was completed in 63 consecutive calen-

Cleaning up the Completed Surface

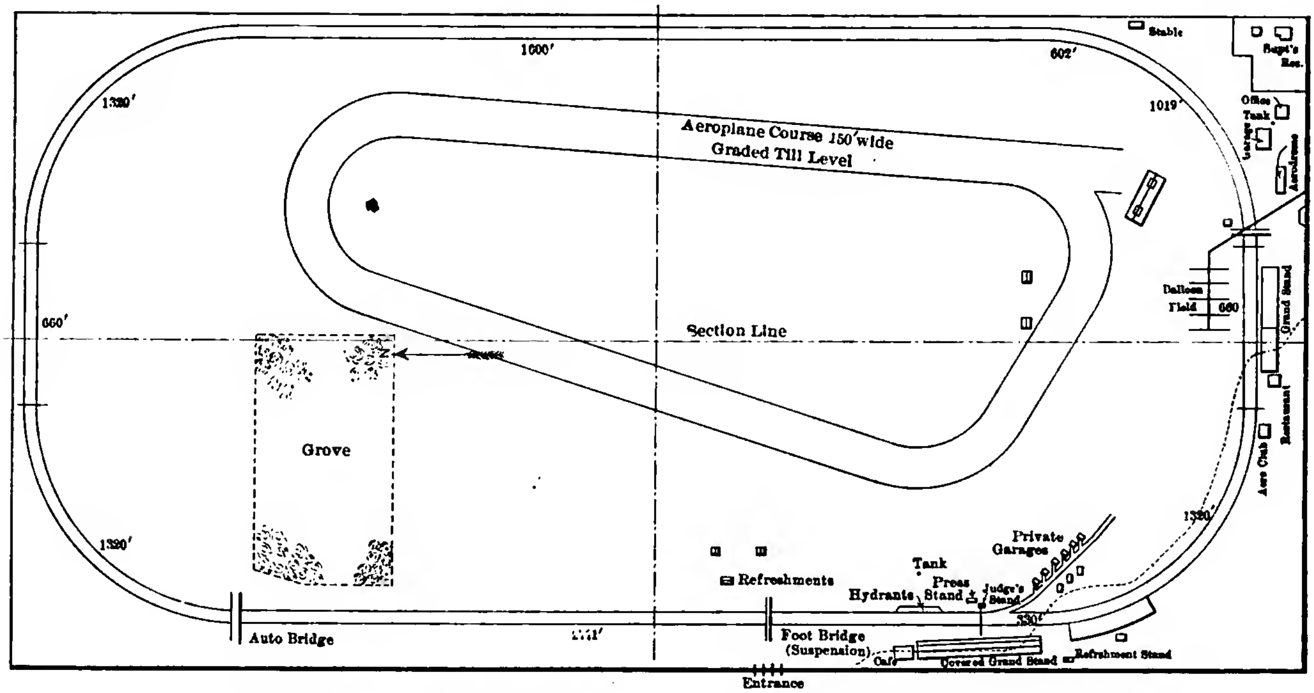


Fig. 1—Plan of speedway, showing present track, location of bridges, buildings in place, and other details

dar days; the biggest single day's work of laying the brick was 140,000 brick laid in nine hours. These brick weigh a trifle less than 10 pounds each, and lie in the pavement 37 to the square yard.

A portable belt conveyor was used for carrying the brick from the piles along the track to the setters; it was mounted on wheels to aid in handling, and was advanced along the pavement following the brick setters at about 10-foot intervals, and was run by an automobile engine.

The brick were piled along the track in piles 10 brick wide, so that a clamp holding five brick would adjust itself to the pile without rehandling the brick. From the pile they were lifted in clamps and placed on the conveyor and removed by clamps and placed where required by the setters, and by this method it was found that one man averaged 11.4 tons of brick from the piles to the pavement in nine hours.

Before laying the brick a two-inch sand cushion was spread over the old track surface and luted to an absolute place surface by a drag working on wooden strips, which were set to grade. On this cushion the brick were laid. A three-ton tandem steam roller then rolled them to a true surface, and the pavement was then subjected to an inspection for grade and plane.

The filler was then applied; it was composed of equal parts of sand and portland cement mixed by hand in special boxes to the consistency of a thin batter and removed from the boxes to the pavement with a 14-inch scoop shovel, but no dump boxes were used for this work.

In order that the joints between the brick be filled absolutely flush with the surface of the brick, a second coat of the filler was applied about one hour after the first coat; this second coat was not broomed off, as the first coat was, but was floated ahead at an angle of 45 degrees with the joints in the brick with a "squeegee" having a rubber face very much like the rubber-faced window cleaners in common use.

Buildings, Lighting Plant and Aviation—The main grand stand is a covered structure 82 feet wide and 500 feet long, and there are two bleachers, one 500 feet by 60 feet and one 350 feet by 65 feet.

An aerodrome 300 x 50 and 35 feet from floor to ceiling is arranged with sliding doors forming one entire end of the structure, which has a truss roof. In addition, there are 42 other buildings, comprising office, superintendent's residence, stables, garages, cafés, clubhouses, rest rooms, etc.

Three miles of tight board fence eight feet high, surmounted with barb wire, surround the grounds, the posts being set in concrete. There are seven miles of wire fence in the infield and around the track, and 1 1-2 miles of eight-foot picket fence. Two suspension bridges for foot traffic cross the track, giving egress

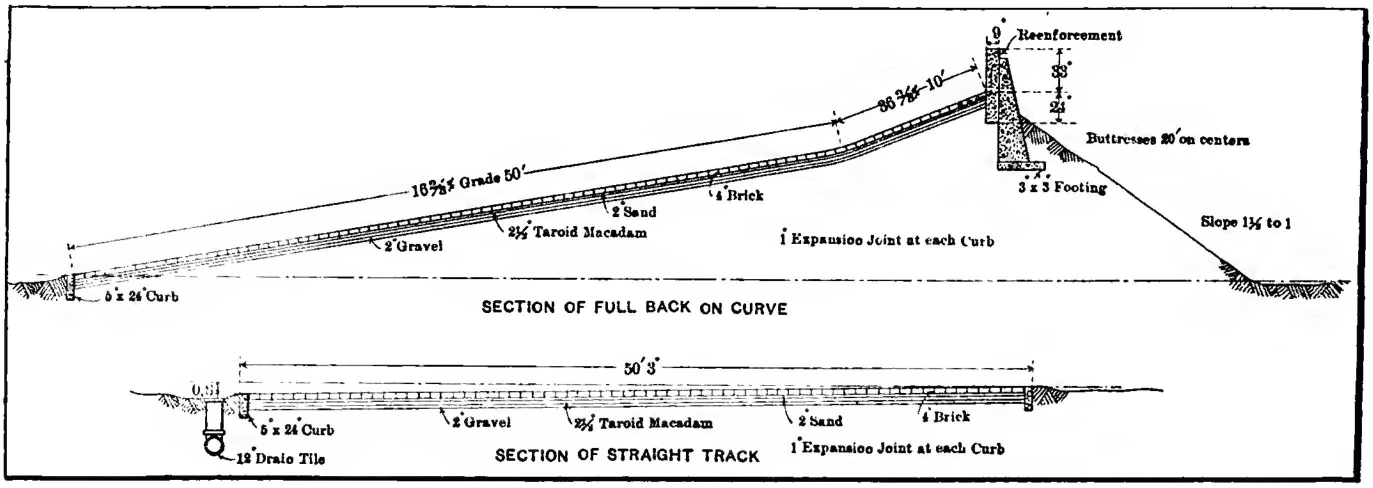

Fig. 2—Detail of embankments, showing buttresses, slope, reinforcement, and other details of construction

from the infield during the races. A truss bridge for vehicles affords entrance and exit to and from the infield during races.

The generators, gas holders, fittings, reflectors, etc., for a night lighting of the entire track at intervals of every 20 feet have been purchased and are on the grounds, and work will be started on their installation as soon as the speeed trials have been run.

An inner course for aeroplanes 150 feet wide and 1 1-2 miles in length is being graded and rolled in the infield to a uniform plane; this will permit an aeroplane to alight at any point in its course and reascend without danger of straining the machine.

Warner Timing Equipment Provided—An automatic timing device was installed by the Warner Autometer Company, which registers in the judges' stand the exact instant at which the tires touch a small hose stretched across the track, serving for the time-honored "tape." In addition to provisions for properly recording time, as the instrument above named, every provision is made to handle the spectators, so that, non-interference with the events will be assured.

Other Uses to Which the Track Will be Put—One of the prime objects of this Speedway is to afford, to the builders of automobiles, at Indianapolis, and in the vicinity, a place to try out new models before they are turned over to purchasers, thus assuring that they will be properly tuned up and so timed that the best possible results will be realized. Advanced models, prior to building in quantity, may also be given the hardest kind of service, within the shortest possible time, and it is the reasonable expectation of the companies at Indianapolis that the track will be of the greatest service, to the makers of cars, and the users as well. That the track will pay interest on the whole investment, is practically assured from the start. The arrangements, from the point of view of policing, are all that can be desired; there is no occasion for anyone crossing the track, and as to accidents, there should be none.

TEXAS ENDURANCE RUN BREAKS RECORDS

Ft. Worth, Tex., Dec. 8—In the recent endurance run from Dallas to San Angelo and return, a distance of nearly 800 miles, all records were broken, not for speed but for mud-plugging. Of the nine cars, and a pilot car, which started from Dallas on Monday morning, but six were left at the second night control, Abilene. Between that point and the finish, another car was eliminated by the fearful road conditions.

In the original program the finish had been planned for Ft. Worth Friday afternoon, but Jupiter Pluvius planned otherwise, and as a result of the week-long downpour a whole day was added and the race finished late Saturday night.

After the technical examination, which kept the committee busy all day Sunday, the winners were announced as follows:

Moline, J. A. Wickes, driver, endurance cup.

Auburn, "Skeet" Hall, driver, economy cup.

Fisk tires, tire cup.

This run was organized and managed by the Ft. Worth *Star-Telegram*. As an endurance run, it was easily the feature event of the year, for the hub-deep mud from one end of the route to the other made even hardened drivers who had been through the Glidden and similar tours get out and work as they had never worked before. Wickes, who drove the Moline, is the same one who took a car of this make through the Glidden. Goldthwaite, who drove a Maxwell, and Illingworth at the wheel of another Maxwell, are both Glidden tour drivers. All three expressed the opinion that the first three days' work of this tour were far harder on both men and cars than the whole two weeks of the Glidden just past. All who witnessed the event, agree that it was conducted in a most painstaking way and that the promoters had the right idea in relation to the mapping out of the course and the management of the details.

Kincaid in National Winning in His Class

Robertson Driving Simplex—Twice a Winner

POSTPONED FORT LEE CLIMB SUCCESSFULLY RUN OFF

FINAL events of the Edgewater-Fort Lee hill-climb on the Palisades, opposite New York City, which were postponed from December 4 on account of the interference of the spectators, were run off last Friday afternoon in the presence of a smaller and more orderly crowd. The conclusion failed to receive the amount of free advertising that the start did, and as a result, many people in New York heard nothing of it. The day, too, Friday instead of Saturday, tended to diminish the attendance

George Robertson, in his Simplex, made the best time, setting a record of 53 2-5 seconds, some three seconds less than Kincaid's mark in the December 4 session. In addition, Robertson won first place in the event for gasoline stock chassis of 451 to 600 cubic inches piston displacement with a mark of 56 seconds. Kincaid bettered his former record by going the distance in 55 seconds. A Stanley steamer, driven by H. W. Bell, made the second best time for the hill, 54 1-5 seconds.

That the ascent was no child's play was again demonstrated by an accident to Ray Howard, driving a Stearns. He attempted to take the sharp final turn at too high speed, and his car crashed into the curb on the outer side of the street. The right front wheel was shattered, but the car did not overturn. Howard got a bad shaking up, but received no injury. The accident was much the same as that which sent motorcyclist Kledes head-on into the foundation wall of the house on that corner. The summary of the final events follows:

GASOLINE STOCK CARS, FOUR CYLINDERS, $4,000 OR OVER

Simplex, George Robertson	90	0:53 2-5
Stearns, E. Badenhausen	30-60	0:58 2-5

NEW YEAR'S ENDURANCE BY CENTURY M. C.

PHILADELPHIA, Dec. 13—William Reuss (chairman), H. R. DeGroat, Dr. W. H. Moore, T. C. Davis, Jr., W. A. Daily, William H. Booker, H. T. Uhler, F. R. Isaac, E. V. Stratton and H. C. Evans have been named by President Hartman as the committee to manage the New Year's endurance run of the Century Motor Club. Rules and entry blanks have been distributed, and over a dozen entries have already been secured—rather quick work, when it is remembered that the run was not decided upon until the Quaker City Motor Club announced the abandonment of its annual fixture only ten days ago.

The route, as finally fixed upon after reading the report of the pathfinders who went over it last Monday, will touch Paoli, West Chester, Kennett Square, Wilmington, Chester, Media, Morton, Darby, Llanerch, Valley Forge, Phoenixville and Norristown, in the order named—about 150 miles.

OLDFIELD MAKES AN ARCTIC RECORD

DALLAS, TEX., Dec. 8—Barney Oldfield broke the 50-mile circular track record, which has stood for over five years, with a spectacular ride in the teeth of a fierce "norther." He covered the distance in 47.18, as against the old mark of 48.40 1-5, which he made at Fresno, Cal., in 1904. He got inside the old record at thirty miles and broke every mile mark to the end of the run. The car was his 120-horsepower Benz.

The track was frozen hard and Oldfield had his face wrapped in woolen bandages and wore heavy fur gloves and fur overcoat. At the finish his hands had to be pulled loose from the steering wheel by an assistant, so affected were they by the strain and the intense cold. H. A. Green, a member of the A. A. A. contest board, acted as referee, and as the meeting was sanctioned by the national association, the record will probably be accepted as official.

SOME RECENT BRITISH AUTOMOBILE DOINGS

LONDON, Nov. 27—Friday saw a memorable celebration in the shape of a banquet at the Hotel Cecil to commemorate the twenty-first anniversary of the practical discovery of the pneumatic tire. Some four hundred guests assembled, including official representatives of every society or club in any way connected with road locomotion. Prince Francis of Teck took the chair, while the guest of the evening was Harvey du Cros, M. P., to whose keenness and energy the development of the tire was due. At the conclusion of the speech-making Adolphe Clement announced that the French Government had decided to confer the Cross of the Legion d'Honneur on Mr. du Cros.

From the official statistics that are available, it is clear that the recent Olympia show surpassed in number of exhibits any previous European exhibition, while in the matter of attendance it outshone any previous British show, at least. The total number of cars and chassis on view was 597, as opposed to 575 at the 1908 Paris Salon. The British productions totalled to just over one-half. The figures were: Britain, 307; France, 178; Italy, 28; Germany, 26; Belgium, 21; United States, 16; Switzerland, 15, and Austria, 6. One other synopsis shows conclusively which form of transmission has become popular; cars with propeller shaft numbered 556 and those with chains 32. The remaining nine cars had special forms of transmission.

Regarding the attendance at the show, the total number of people passing the turnstiles was 195,000, an excess of 40,000 over the figure for last year. The best day was Thursday, November 17, when 32,567 people entered.

A company has been formed to manufacture a new composite fuel called "Rapidin." This is a German invention and consists in a method of treating the heavier petroleum oils so as to obtain light spirits suitable for automobile use. To quote from the inventor's description. "One hundred kilos of ordinary kerosene of specific gravity 0.83-0.87 are mixed with half a kilo of caustic potash and twenty kilos of benzol of specific gravity 0.9. After having been vigorously stirred, the mixture is allowed to rest for about six hours, after which it will be found to have a specific gravity below 0.8 and to contain as a sediment the matter separated from the kerosene by the caustic potash. If this mixture were distilled it would separate into its components, but if there be first added to it a material rich in carbon, such as a gum or resin, and also a nitro-compound, such as picric acid, the liquid will distill uniformly. The lighter portions of the distillate—about 40 per cent.—are suitable for use as motor spirit, while the remainder can be used as a solvent for fats and also, in part, as a substitute for turpentine.

A season without any road racing has not been altogether pleasing to all sections of the motoring community, and many people are desirous that the same policy of inaction shall not be adhered to for 1910. The first definite proposal was for another tourist trophy race in the Isle of Man, with engines limited to four cylinders of 3-inch bore. Of late, however, more daring individuals have suggested the revival of the Gordon-Bennett race in all its glory, the proposed scene of the contest being the old Irish course. The realization of this idea is not unlikely.

ROUGHING IT ACROSS THE WESTERN PLAINS

ON a pleasure jaunt, driving from Chicago to San Francisco, a party from the first mentioned city recently established a new record between the cities, traveling only by daylight, and making the distance, over 2,800 miles, in 19 days and a few hours. The trip was made in a 30-60-horsepower Stearns, driven by George C. Rew, who was accompanied by W. H. Aldrich, Jr., R. A. Luckey and H. G. Tony. They were prepared to "rough it" in good shape, and they did, for on more than one occasion they camped over night in the big Stearns, building a canvas "lean-to" against the side of the car.

Not only was there a complete absence of mechanical troubles on the trip, but there was also an absence of tire trouble, barring one puncture, and that was caused by a spike while driving on the ties of tracks of the Union Pacific Railroad. As demountable rims are standard equipment on all Stearns models, the change was made in a few moments. Mr. Rew and his party went Charles J. Glidden one better in driving on the railroad tracks, for while the premier tourist of the world used flanged wheels and glided smoothly along, the big Stearns was driven over the ties for many miles. Barring the time when the car was driven down the side of an embankment to make way for a fast mail train, the trip along the roadbed was without incident, except the one puncture noted above.

Near Battle Mount, Wyo., the car was pressed into service to carry water to a band of cowboys working on the annual fall round-up. A small barrel of the precious fluid was taken 25 miles across the plains where there was no semblance of roads. The "punchers" had noticed the water bags on the car, and a request for aid brought a quick response from the autoists.

The trip through the Western mountains was spectacular in many ways. The party chose a route away from the ordinary run of transcontinental travel, passing through many sections where no automobile had been before. When the car finally rolled into San Francisco it was found that the time for the daylight trip between Chicago and the coast had been broken, although no attempt at the record had been made.

George C. Rew's Party, in Stearns, Bringing Water to Cowboys at Battle Mount, Wyoming

WHY FRENCH MOTOR MAIL DELIVERY IS A FLAT FAILURE

PARIS, Dec. 7—Although Paris was the first city in the world to adopt automobiles entirely for the carriage of mails from suburban to central offices, and from the central to the various railroad depots, it cannot be accepted as a model to be followed, so far as details of organization are concerned. Within one year of the complete conversion from horses to automobiles the contracting company has declared itself bankrupt, has abandoned its wornout vehicles to the authorities, and the Postmaster-General after vainly endeavoring to get another company to take over the transportation of mails, has been obliged to do the work himself with the material of the bankrupt company and temporary assistance from taxicabs.

The failure is due to bad management and not to any inferiority of the mechanically driven vehicle compared with the horse species. About five years ago the postal authorities, in order to allow of later closing of the mails in the sub offices, experimented with electric wagons in place of horse vans. The electrics soon proved unsatisfactory, and gradually attempts were made with gasoline vehicles. With a view to economy some of the old horse vans were transformed into unsightly automobiles, and in still more numerous cases the bodies of the horse vans were mounted on automobile chassis.

Towards the end of 1908 a Lyons syndicate connected with the La Buire Automobile Company entered into a contract with the postal department for the entire transportation of mails in Paris by automobile. About 150 closed vans were to be put into service, 30 of this number being considered as reserve. They were of three different types, carrying loads of, respectively, 1800, 2600, and 4000 pounds. The mileage was fixed at an average of 50 per day for each vehicle, and the average speed for the journeys had to be not less than 13 miles an hour.

A bad start was made with only half the necessary number of automobiles, the result being that in order to carry all the mails these had to be kept running for twenty-two hours a day, making proper verification difficult and repairs almost impossible until the vehicle had been completely put out of business.

It was not long, too, before the contracting company found it had made a serious mistake in guaranteeing an average speed of 13 miles an hour in Paris. The central post office is in the most crowded portion of the city; the railroad depots are also situated in districts where street traffic is most intense. The individual journeys were never more than two or three miles in length, with the result that if two or three minutes were lost at the commencement through a block in the traffic, an excessively high speed had to be maintained to gain the time lost. An average of 13 miles an hour in Paris meant speeds at certain moments of 25 to 30 miles an hour.

Such a rate of travel was disastrous to the vehicles, obliged to advance by leaps and bounds, throttle wide open as long as possible, with harsh usage of the brakes when collisions were inevitable. It was equally disastrous to the public, accidents taking place every day, some of them, unfortunately proving fatal. With its 150 automobiles in a wornout condition and ruin staring it in the face, the company a few days ago refused to continue with its contract, although this refusal meant the abandonment of all its vehicles to the postal authorities. Under the contract the company had undertaken to carry the mails at a rate which practically worked out at 17 cents a mile. In view of the high speed and exactitude required this sum was found to be far too low. For an ordinary delivery service, where speed was not absolutely necessary, and in districts outside of Paris, where gasoline is cheaper, it might have been possible to make a profit. It proved impossible to do so in the case under consideration.

At present the postal authorities are running the automobiles themselves, but being without expert management, and having to deal with a fleet of vans almost worn out from neglect and overwork, have to rely considerably on outside aid from the taxicab companies. An endeavor has been made to find a company willing to run the abandoned automobiles, but without success. It will doubtless be necessary for the postal authorities to undertake the service itself to the best of its ability until a fresh company has had time to get together a fleet of automobiles. It is certain that in order to obtain a satisfactory service the postal authorities will have to be prepared to pay a higher price and be content with a lower average speed, unless some badly needed improvements can be made in Paris traffic conditions.

Despite the unsatisfactory nature of this first attempt to abolish the horse in the mail service, the authorities have no intention of abandoning mechanical traction. The time saved and the greater reliability are too considerable to allow of the horse being introduced again. Even when the present badly organized scheme was at its worst relief was obtained not from the horse owners but from the automobile taxicab companies. The only work that is left to the horse in the Paris postal service is in drawing the buses which carry the letter distributors to their rounds. As the distance is not great and the men drop off the vehicle every few hundred yards on reaching the commencement of their rounds, the slow speed of the horse bus is to be preferred to the more rapid automobile.

PARIS TAKING LESSONS FROM NEW YORK

PARIS, Dec. 8—Paris is now taking lessons in traffic regulation from New York. Colonel Eno, who claims to have done much to put traffic straight in New York City, undertook to train the lawless Parisian driver to a true respect for the rules of the road. The first experiment has been made in the Rue de la Paix, at this time of the year one of the most crowded streets of the city between 2 and 5 p. m. Mounted municipal guards were instructed under the direction of the American colonel to perform the same service as the mounted police in New York City. The guards occupied positions at intervals down the center of the street, and made the traffic keep in well-defined lines, not more than three abreast in each direction. It was forbidden to cut across the street in the free and easy manner of the Parisian cab driver, crossings being made on the American system at the intersection of streets only. The experiment having proved such a success, it is intended to extend the system to other portions of the city and continue it until the drivers are thoroughly trained.

PEERLESS OPENS NEW YORK SALESROOMS

NEW YORK, Dec. 13—This city has many magnificent and elaborate automobile salesrooms, but the one just opened to-day by the Peerless Motor Car Company, on Broadway, corner of Fifty-seventh street, will rank with the finest of them. The opening, too, ranks with anything in this line ever attempted. Hundreds of guests dropped in during the day to inspect the decorations. Among others who participated in the housewarming were Vice-President E. H. Parkhurst and Treasurer F. I. Harding, of the Peerless Company of Cleveland; W. H. Johns, E. H. Broadwell, Archie Hughes and Percy Neil, of Philadelphia; G. H. Smith, of Newark; Joe Ball and Harry Pike, of Detroit; E. N. Carples and Frank Bowen.

ACETYLENE BURNER PATENT INVALID

WASHINGTON, D. C., Dec. 11—The Supreme Court of the United States has declared invalid the Dolan patent, number 589,342, which was claimed to cover all commercial forms of acetylene burners. The cases were styled those of D. M. Steward, M. Kirchberger, *et al.*, vs. the American Lava Company and Paul J. Kruesi, and M. Kirchberger *et al.* vs. the American Lava Company and Paul J. Kruesi. The decision supported that of the U. S. Court of Appeals and ends seven years of litigation.

MASSACHUSETTS WARNS CARELESS NIGHT DRIVERS

Boston, Dec. 11—Because of the many accidents that have resulted from improper operation of automobiles at night the Massachusetts Highway Commission has issued a warning in which it says that it will take summary action in all cases in which the requirements of safe and proper operation are not complied with. The text of the warning follows:

A number of accident cases have been heard by the Massachusetts Highway Commission within the last few months which have made plain one frequent cause of great danger to both the automobilists and the public in general. That is the operation of automobiles when there is not light enough to enable the road and the persons using it to be seen clearly, at such a rate of speed that the operator is not able to stop his car in time to avoid a collision. These accidents, and there have been many of them and several resulting in death, have invariably happened when the automobile had no cetylene gas lamps lighted. The operator, without them, could not see far enough ahead at the speed at which he was moving to stop in time.

Automobiles have collided from this cause with derricks, platforms, teams going in the same and in opposite directions; have run over foot passengers and have even run through a board fence and dropped onto a railroad track. While there is no provision of law requiring the use of searchlights and possibly they are not needed in well-lighted city streets, the commission feels that it should call the attention of all automobilists to the matter, since operators who have come before the board have seemed to think that if they were upon the right-hand side of the road, and if they had the lighted lamps which the law does require, and if they were not operating at a greater speed than the law permits at that point on he road, no fault could be found with them if they sruck, for example, a foot passenger who was in the road, and who, they claimed, should have been on the sidewalk.

In one case a foot passenger was not seen because of an electric light which may have dazzled the operator somewhat. Every operator must realize that when he has no searchlights he cannot see far beyond a bright electric light and that he runs quickly into a dark zone. Such conditions have caused two deaths, at least. The board feels that operators cannot be exonerated from blame under such circumstances, and that, whether they have searchlights or not, all persons are bound to operate at a speed which is reasonable and proper under the conditions which exist. And a speed is never reasonable and proper if, under any conditions, the operator cannot stop his car when he sees an object on the road, before he strikes it. If necessary, he must stop his car and cease to operate when he cannot run it so as not to endanger other users of the highway who are exercising reasonable and due care.

This rule should be applied not only where the streets are imperfectly lighted, or where one is dazzled by an electric light, whether a street light or that of a street car, but around corners and curves, or where one's view is obstructed by other vehicles in passing, or when one cannot see clearly because of a fog or mist. The board feels compelled to make this announcement at this time because of the many recent accidents and fatalities in which both pedestrians and occupants of automobiles have been involved. It desires, therefore, to give notice to all automobilists that it will take summary action in all cases coming before the commission when it develops that the foregoing requirements for safe and proper operating have not been complied with.

WISCONSIN OIL INSPECTION LAW IS CONSTITUTIONAL

Milwaukee, Wis., Dec. 13—The Wisconsin oil inspection law of 1909, which requires the official inspection and branding of every gallon of gasoline and kerosene used in Wisconsin, has been declared constitutional by the Wisconsin Supreme Court in the suit of the Wadhams Oil Company, of Milwaukee, a big independent concern, for an injunction to restrain Chief Inspector Edward L. Tracy from enforcing the law. The State charges a fee of 10 cents for every barrel inspected. About 750,000 barrels of gasoline and kerosene are used every year.

TO MAKE ROAD SIGNS COMPULSORY IN MARYLAND

Baltimore, Dec. 10—A bill making it compulsory for the city, county, town and village authorities in every section of Maryland to erect suitable signs and signposts for the guidance of motorists has been drawn up by Col. Sherlock Swann, a member of the Maryland Automobile Commission, and will be passed at the coming session of the State legislature, which convenes in January. The bill says that the officials referred to shall erect and maintain at or near the boundary lines of all important thoroughfares leading out of the various cities, towns and villages, and at every place of intersection of important highways in the counties guide posts for the direction of motorists. These posts shall be not less than eight feet high, and near the upper end of them shall be placed signs of metal or wood which shall contain in plain letters and figures the names of the next towns or places to which each road leads, the number of miles to the same and the figure of an arrow pointing towards such towns or places. The bill further prescribes that it shall be the duty of the State Roads Commission to see that the law is enforced. Persons destroying such signs are liable to a fine not exceeding $25.

DON'T FORGET YOUR LICENSE IN THE NUTMEG STATE

Hartford, Conn., Dec. 13—Police are rigidly enforcing every provision of the new State automobile law and the autoist who forgets to have his license card with him will be liable to land in a police court. Early in the week a repairman at a local garage took down a rear axle to repair it and in doing so removed the rear number. When the member was again in place he thought he would try out the car around the block. He left off the rear marker. A member of the police traffic squad saw that he did not have the rear marker and he was ordered to appear in court the next morning. He pleaded guilty to not having the rear marker in place and although he explained the situation to Judge Clark he was fined $5, and in addition to the five he had to pay $2 more, as a record of the trial has to go to the Secretary of State. For this bit of work the clerk of the police court is reimbursed to the extent of $2.

There are now pending before the Secretary of State three cases where motor-car drivers are liable to lose their licenses. The testimony is all in and the matter now hangs fire.

BILL TO STOP JOY RIDING IN KENTUCKY

Louisville, Ky., Dec. 13—At a meeting of the Louisville Automobile Club, held Tuesday, the secretary was instructed to request every autoist in the State to aid in the passage of the bill to be introduced at the next session of the legislature by Senator Herman D. Newcomb, making it a felony for anyone to use an automobile for any purpose without the consent of the owner and, upon conviction, the offender shall be punished by a term in the penitentiary of not less than one year. This is aimed at joy riding. The bill to be introduced follows:

Be it enacted by the General Assembly of the Commonwealth of Kentucky:—That any chauffeur or other person, who, without the knowledge and consent of the owner shall take or cause to be taken from a garage, stable or from any other building or place, an automobile or motor vehicle and operate or drive, or cause the same to be operated or driven for his own profit, pleasure, use or purpose, shall he deemed guilty of a felony, and upon the conviction thereof shall be punished by a term in the penitentiary of not less than one nor more than three years.

What the Clubs Are Doing These Days

DENVER MOTOR CLUB'S COMPREHENSIVE PLANS

DENVER, Dec. 4—The Denver Motor Club, which is now nearing the end of its second year of existence, is already making plans for the coming season. The officers of the club have decided to call a good roads meeting in the near future to which the county commissioners, the board of public works, the Denver Real Estate Exchange, the Chamber of Commerce, and similar bodies will be invited. This meeting should be the biggest one ever held in Colorado.

The excellent work carried on by the penitentiary commissioners with convict labor has shown wonderful results, especially in the southern part of the State. During the past season 300 convicts were employed in this manner.

Several ordinances have been passed by the Denver council which have greatly pleased automobilists in the city. One of these requires slow-moving vehicles to keep near the right-hand curb, an idea already adopted by other large cities. Much good work has also been done in breaking up joy-riding.

For the coming season the club plans a number of events, which are announced as follows: Two road races, one on Decoration Day and one on Labor Day; a reliability contest in June; a gasoline economy contest in October, and a hill-climbing contest in November.

NEW ROAD BETWEEN PHILADELPHIA AND BETHLEHEM

PHILADELPHIA, PA., Dec. 13—Through the efforts of the Automobile Club of Philadelphia, the stretch of bad going on the Sellersville road, between this city and Bethlehem, is being macadamized, the work being nearly completed. The members of the good roads committee passed round the hat, and, after securing sufficient to start the work, went ahead, relying upon the generosity of automobilists to complete the fund. There expectations seem in a fair way of being realized, as small contributions began pouring in from all directions when the papers began to exploit their enterprise. While the new route is a third of a mile longer, it will furnish tourists with a perfect bit of road and save each car thirty cents in toll charges.

BIG CROWD EXPECTED AT NEWARK, N. J., BANQUET

NEWARK, N. J., Dec. 11—H. D. Bowman, A. B. Le Massena and Joseph H. Wood, the members of the committee in charge of the annual banquet of the New Jersey Automobile and Motor Club January 24, expect a greater number of applications for seats than at any of the previous annual dinners of the organization. The banquet is to be held at the New Auditorium in Orange street, Newark. The membership of the club is now close to 1,900, and additional members are being elected at every meeting of the club's board of trustees. The banquet committee is now arranging for the presence of several well-known men to speak.

DENVER MOTOR CLUB AFTER AUTOMOBILE THIEVES

DENVER. Nov. 27—As automobile thieves are again becoming active in this city, the Denver Motor Club has begun a vigorous campaign. An advertisement has been inserted in the daily papers offering a reward of $100 for the arrest and conviction of anyone stealing an automobile belonging to a club member. The club has had one of its officials sworn in as a special police officer, and in addition has secured the co-operation of the regular police force. Any person caught will be prosecuted to the full extent of the law, as the situation demands most drastic measures. Trouble is also in store for anyone who abstracts tires, lamps, robes, tools or other accessories.

QUAKER CITY MOTOR CLUB'S ANNUAL BANQUET, JAN. 6

PHILADELPHIA, Dec. 13—The decision to drop the punishing New Year's run from its fixture list has given the Quaker City Motor Club's workers an opportunity of concentrating all their efforts on the club's annual banquet, on Thursday, January 6, at the Hotel Walton, and from present indications that affair will be the banner event of the Quaker's social season. Among the notables who have accepted invitations are: Governor Stuart, Mayor Reyburn, Congressman "Hamp" Moore, Director of Public Safety Henry Clay, Mayor Stoy, of Atlantic City; State Senator Webster Grim, Director Neff, of the Department of Public Health and Charities; President Hazlett, of Select Council; President McCurdy, of Common Council; United States Senator Penrose, Director Hasskarl, of the Department of Wharves, Docks and Ferries; numerous prominent lights of the American automobile and newspaper worlds, and others.

The success which attended the recent Fairmount Park race has given the club such prestige that the guest list will be something out of the ordinary, and what would under ordinary conditions have been a strictly local function now promises to attain the dimensions of a national symposium.

NEW YORK COMMUTERS AFTER COWBOY POLICEMAN

NEW ROCHELLE, N. Y., Dec. 11—The board of governors of the Automobile Club of New Rochelle held a special meeting to act on the case of a New Rochelle policeman who shot at Harvey Husted's car on November 15, and called the attention of the police commissioners to the fact that the officer in question was not in uniform and did not display his badge. The governors have given out a statement in which they say that the manner of arrest and the malicious and unwarranted use of firearms were illegal and dangerous to public safety, and that the city of New Rochelle is liable for damages.

LOUISVILLE, KY., LOOKS FORWARD TO NEXT RUN

LOUISVILLE, KY., Dec. 6—Tentative plans were discussed at a meeting of the Louisville Automobile Club for the second annual reliability and economy contest, to be held next year. The second run will probably be through the western part of the State and may extend south as far as Nashville, Tenn.

When Eugene Straus, president of the club, finishes his work on the touring book, it will contain the most complete and correct maps ever made of this section of the country.

ERROR IN ANNOUNCEMENT OF CHICAGO DIRECTORS

CHICAGO, Dec. 11—Officials of the Chicago Motor Club have announced a change in the board of directors of that organization elected at the annual meeting last week. The first announcement of the results of the election included Joseph B. Deibler as a member of the board, but when the votes were recounted it was found that Charles E. Gregory had received more votes than Mr. Deibler. The officials thereupon announced the corrected list of directors, with Mr. Gregory's name in place of Mr. Deibler's.

DELAWARE PLANS NEW YEAR'S ENDURANCE RUN

WILMINGTON, DEL., Dec. 4—George Proud, of Philadelphia, representing the Century Motor Club of that ciy, was here today in the interest of a roadability run to be given on New Year's Day to Wilmington and return, by way of Chester and West Chester, Pa. The club desires to interest the Board of Trade in each town and to get them to co-operate to the extent of having machines in the run representing their cities.

CHICAGO CLUB'S GIGANTIC SIGN-POSTING CAMPAIGN

CHICAGO, Dec. 13—The Chicago Motor Club is bringing to a successful completion a campaign for signboarding the country hereabouts which has been spread over 2 years and which has engaged the services of an energetic committee. The latter has gone about the matter in such a scientific manner that it is thought the groundwork has been laid for a system that eventually will mark the country roads in as effective a manner as are city streets, so that your motorist can travel from town to town in Illinois, Indiana and Wisconsin without having to stop at every cross-roads to inquire the way. If the calculations of this committee prove correct all the motorists of the future will have to do when he comes to strange cross-roads is to consult the cast-iron signboard of the Chicago Motor Club and be "put wise."

In laying this foundation the Chicago Motor Club has been wise enough to peer into the future and realize that eventually this signboarding must be attended to by the various counties because of the fact that when the posts are put up through private enterprise like this there is nothing to protect the post and its sign from the depredations of those miscreants who find their enjoyment in destroying something that has been put up by other than official authority.

Then, too, the cost of such signboarding is so great that it is folly to expect motoring interests to stand all the expense. Therefore, the Chicago Motor Club has figured that by taking four of the big trunk lines running out of Chicago and properly marking them that this will be an object lesson with which it and the allied interests may go before the county supervisors and ask that all roads be treated in a similar manner. Also, after this education has been completed, it will be possible to invoke the aid of the legislature either to compel the enforcement of the old law or enact a new one that will make it compulsory on the part of the road supervisors to see that all the roads in their respective territories are properly marked.

Farmers' Antipathy Gradually Lessening—Much of the antipathy toward motoring enterprises may be done away with by this educational step taken by the Chicago Motor Club. If the farmers see that the motorists are willing to bear their share of the expense and that the object of the motorists is the common good then they will be more amenable to reason. In another five years it will come easy for the road supervisors to attend to this part of the work.

With the ground work well laid through the enterprise and bustle of the signboard committee, at the head of which Joseph V. Lawrence has served for the past two years, the Chicago Motor Club proposes to have for two cardinal points, good roads and signboards, believing that they are the cornerstones to motoring successes in this vicinity. But the club believes there should be a community of interests and that success in both these departments only can be achieved by the banding together of the leading clubs and organizations; that success only can be achieved in this manner.

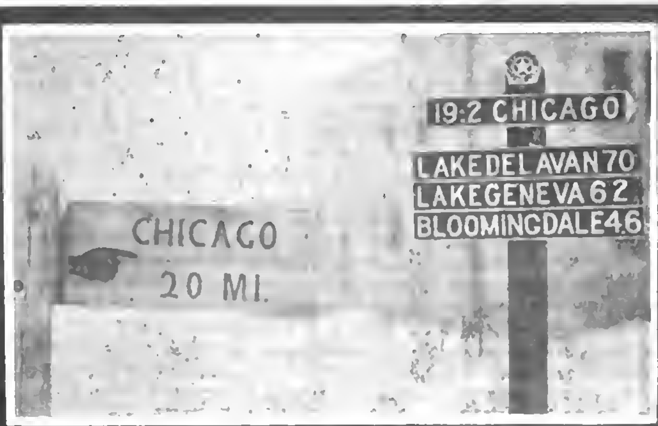
The signboard campaign really started some three years back when the Illinois signboard commission was formed and nearly $100 raised by popular subscription to push the work along. Some signboards were purchased and a few put up, then interest in the commission slacked and eventually the Chicago Motor Club fell heir to the entire proposition. Then it was realized that an organization scheme would have to be mapped out and the scheme followed through to the end.

It was like a huge business enterprise and had to be carried through slowly. First of all financial support had to be sought, then the organization completed, the routes pegged out, the signs ordered, and finally put up. All this has required time and for the last two years, Chairman Lawrence and his commission has been at work on it. It was not until the last month, though, that the motor club was able to point with pride to the success that has attended its efforts.

Announcement of Completion, a Big Surprise—When Chairman Lawrence arose at the annual meeting of the Chicago Motor Club a week ago and announced that he had practically finished three of the four routes selected and that the last one would be completed inside a couple of weeks, weather favoring him, he surprised the lay members of the club who had not known much of the progress of the compaign, so quietly had Chairman Lawrence worked. Without any blare on the publicity trumpet, Lawrence had quietly sent out his forces and when he finishes this month, he will have expended $2,000 in signs and will have put up 290 posts on which will have been placed 787 signs.

Furthermore, as a monument to the enterprise of the Chicago Motor Club, there will be located at the corner of Jackson boulevard and Michigan avenue in Chicago—the north pole of this motoring expedition—a huge tablet on which will be the direction and mileage of nearly every town of importance within a radius of 100 miles of this city.

Ready for touring next summer will be four routes. The first one completed is to Beloit, the signs blazing the trail by way of Elgin, Algonquin and Lake Delevan. Another route will be to Lake Geneva by way of Rogers Park, Niles Center, Wheeling, Wauconda and Genoa Junction, which route was made possible by E. E. Ayer, who contributed the $500 for marking this course. Both these are done at the present time. The route to Milwaukee has been completed to within 15 miles of the Cream City, work being stopped there because of the condition of the roads which, being muddy, would not permit of the



Old Wooden Sign Alongside New Iron Sign at Road Crossing

One of the Scouts Doing Some Preliminary Work

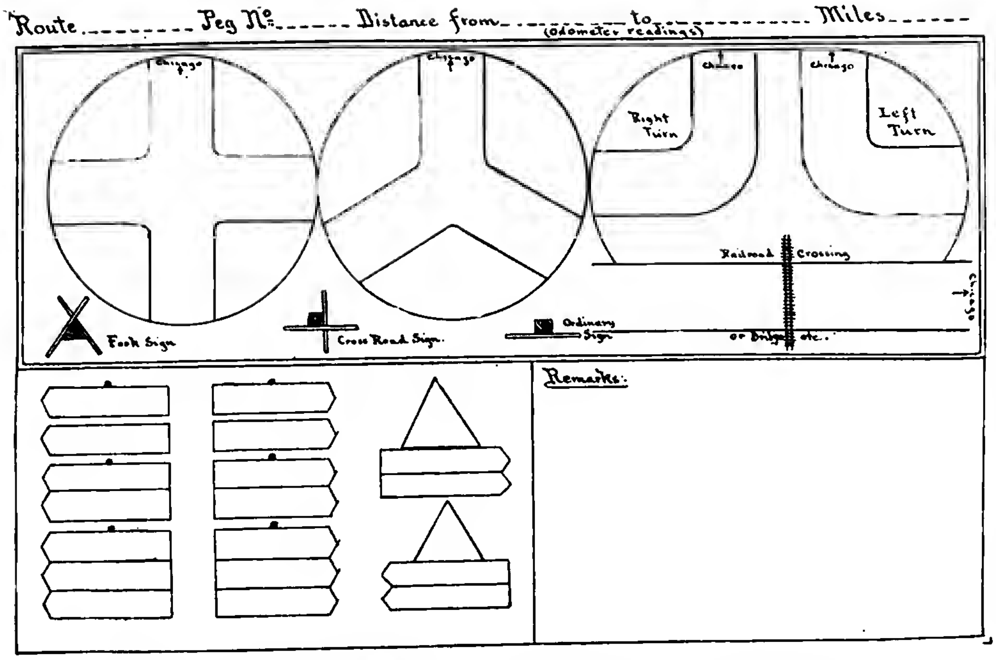


Chart Used by Chairman Lawrence and His Assistants in Preliminary Work

expedition making much progress of a permanent nature.

As soon as the ground is frozen, this work will be completed, the Chicago Motor Car Company, Packard agent, having agreed to finance the proposition. This leaves only the Chicago-South Bend route to be marked and it is proposed to go at this at once so that by New Year's, the four great trunk lines running out of Chicago will have been completed.

Chairman Lawrence then will have completed his task. It being done, he is ready to step down and let others carry on the work. This the motor club proposes to do in an energetic manner, the idea being to interest other clubs and organizations with the intention of appealing to the Legislature for help in this direction.

Very Businesslike Plan Adopted—The plan of campaign followed by Lawrence and his colleagues was most businesslike. He realized that it would be impossible to start at it hit and miss, so the first thing he did was to send out expeditions to mark the various courses, picking out the locations for the signs. To do this he devised a most comprehensive chart, there being a card for each post on which was marked the route, the peg number, the distance from one point to another by odometer.

Then came three cross-road maps in outline. One showed the conventional four corners and on it could be marked just where the post should go. Another showed two roads converging into one that could be marked in the same manner. A third showed a right turn, a left turn, and a railroad crossing. In another part of the chart were the various signboards that were to be put up and the pegger could designate just which one could be used. In this manner, Lawrence and his forces went over the four routes and had all the data required before the signs were ordered. Then the chairman sought bids for the work. It was not his intention to actually put up the signs himself, believing that the work could be done better by paying for it than it could by relying on volunteers. And so it has proved.

From the Featherstone Foundry & Machine Company, the signboard committee secured a bid for the signs. The price agreed on was 65 cents for a cast-iron sign 20 inches long and 4 inches wide; for a double sign the price was $1.15 and for a triple sign $1.75. Where more signs were required on one post it was possible to use several of these styles in combination, as, for instance, the Latrobe steel mills sign at Melrose Park on the way to Elgin there is a sign with seven tags.

In all 787 signs were ordered, the aggregate cost of which was in the neighborhood of $600. Then it came to the selection of posts on which these signs could be placed. The contract for these was placed with the Hines Lumber Company, which furnished 290 tamarack posts 12 feet long and 4 inches square, at a cost of $22 a thousand feet, the total cost being approximately $100.

Equipped with supplies, Chairman Lawrence then sought someone to put up the posts and signs, finally entering into a contract with Joseph T. Elmore and Herbert J. Ross, of the Chicago Ad-Sign Company, to paint, deliver and erect these signs on the different routes at $3.55 a post, the contract netting approximately $1,000. The contract called for painting the

Some of New Signs—At Railroad Crossing, Elaborately Marked Intersection, Dangerous Turn posts with creosote paint, painting the signs themselves with non-rusting paint, painting the letters in white enamel, boring holes in the signs by which they could be fastened to the posts, attaching the signs, and then putting up the posts in holes 4 feet deep. It was necessary to anchor and tamp each post.

How the Signs Were Put Up—Under the contract Elmore and Rose were to provide their own means of transportation. They had intended using a horse and wagon, but Chairman Lawrence was in a hurry to complete the work so he secured from the Randolph Motor Car Company, of Chicago, the use of one of the company's light trucks, the Randolph Company cheerfully donating the use of the machine, but Elmore and Ross paying the expenses of the expedition and the salary of the driver. The Randolph truck proved of greatest benefit to the Commission. Much ground could be covered in a day despite the adverse weather conditions. The truck has been on the job at all times, never giving the expedition the slightest trouble and covering many miles in the course of the day.

The way Elmore and Ross work is to ship a supply of posts and signs along each route, dropping a bunch every thirty miles. Then they come along in the truck, pick up the supplies and place them in the next thirty miles of territory. It requires two men to place the signs. As one man is digging the 4-foot hole in the ground, the other is attaching the sign to the post. It takes about three hours to place a post and sometimes more, according to the conditions. At the Latrobe steel mills it took a day because the ground there is made up of steel filings which made the work specially laborious. In favorable weather the expedition can label a 100-mile course in one week.

Chairman Lawrence reports that his chief difficulty in laying out his routes was to get the necessary permits from the various townships, it being necessary to make several trips to each before these permits would be issued. He found in many places that there was opposition to the idea, the villagers declaring they did not want the signs up because that would bring motorists through their towns, which they apparently did not want. However, after the expenditure of considerable time, all these permits were secured.

In some places, though, Lawrence was greeted with open arms by the villagers, who were sufficiently broad minded to welcome the innovation. At Bloomingdale, on the Elgin route, Lawrence found unexpected co-operation. He had secured the permit and a sign had been erected in that village. It was no sooner up, though, than the report came that some farmers had taken it down and moved it to a point two miles distant for the purpose of misleading the motorists. Just as Lawrence was prepared to investigate, the selectmen of the town acted. They held a meeting and ordered the farmers to put the sign back where it belonged under penalty of prosecution, inside of a week. The sign was moved at once.

In summing up the situation and the expense, Chairman Lawrence finds that in addition to the cost of $3.55 a post, there must be added the sum of 15 cents a mile for pegging out the routes preliminary to putting up the signs.

REDUCED RATES TO NEW YORK DURING SHOW WEEKS

ARRANGEMENTS have been made by the American Automobile Association to secure reduced railroad rates for members of the association who intend to visit New York during the weeks of the two great automobile shows. Open meetings will also be held during these weeks at the National headquarters, 437 Fifth avenue.

The reduced rates apply to points in the following territory: New York, New Jersey, Pennsylvania, Delaware, Maryland, the District of Columbia, Virginia (points of the Chesapeake & Ohio and the Baltimore & Ohio), West Virginia, Ohio, southern Michigan, Indiana, eastern Illinois (points on or east of the C., R. I. & P. from Chicago to Peoria, the T., P. & W. from Peoria to Burlington, and the Mississippi River from Burlington to Cairo), and the cities of Louisville, Ky., and St. Louis. Members outside this territory will find it advantageous to buy tickets to the nearest point at which the reduced rate can be secured, and there buy tickets under the reduced rates.

In amount the reduction will be equal, on the round trip, to two-fifths of the one-way fare. It should be noted that this is not equal to one-fifth of the round-trip fare. Reductions will be made on the certificate plan, the purchaser of the ticket paying the full price at the ticket office, but asking for a certificate. These certificates may be presented for validation to Secretary F. H. Elliott of the A. A. A. The Trunk Line Association will also keep an agent at the Forty-third street entrance of the Grand Central Palace to validate the certificates, for which a fee of 25 cents will be charged. The amount of the rebate will be credited on the return ticket.

Those intending to visit the Grand Central Palace Show may purchase tickets not earlier than December 28 nor later than January 2, and the certificates when duly validated will be good up to and including January 11 on a continuous return trip over the same route. Certificates will be validated on and between the dates of January 4 to 7. No certificates will be validated after this date for any reason, and no refund will be made unless the certificates are properly validated. The reduction is not guaranteed, but is contingent upon at least a hundred certificates being presented by tradesmen desiring to attend the show.

For the Madison Square Garden show the same plan will apply. Tickets may be purchased on and between January 5 and 10, and the certificates will be good on a continuous return as late as January 19. Only members of the automobile clubs associated with the American Automobile Association and individual members will be entitled to these reduced rates. Further information may be obtained from Secretary Elliott, at 437 Fifth avenue, New York.

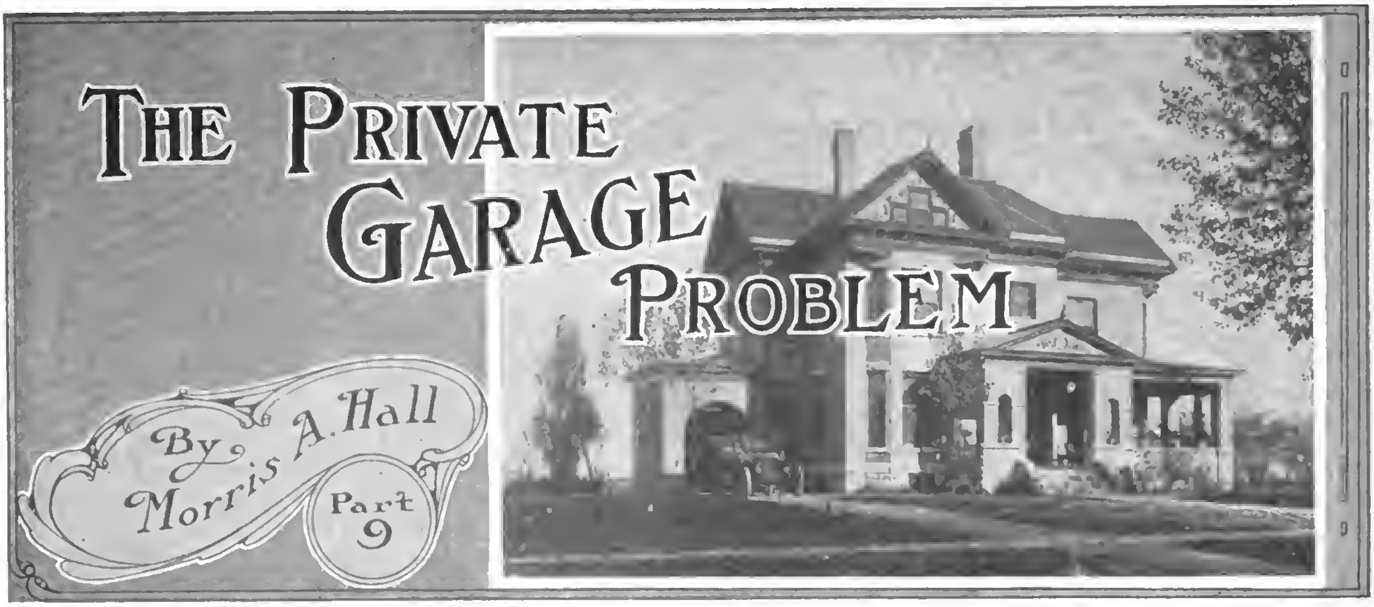
Alfred Reeves, of the show committee of the A. M. C. M. A., has issued a warning that the weeks of the automobile shows are the biggest in the year for the New York hotels, not even excepting Horse Show time, and that prospective visitors should therefore reserve their hotel accommodations well in advance. The Hotel Manhattan will, as usual, be the headquarters of the show committee.

APPLICATIONS OUT FOR NEWARK SHOW

NEWARK, N. J., Dec. 11—H. A. Bonnell, manager of the annual show of the New Jersey Automobile Trade Association, has mailed application blanks to about three hundred dealers in automobiles and accessories. The show is to be held in the Essex Troop Armory, February 19 to 26, and as most of the dealers in Newark have declared their intention of displaying their cars, it is expected that the available space will be contracted for some time ahead. Space on the main floor is to be sold for 70 cents a square foot, and space on the balcony for 40 cents. The applicants or their representatives are to draw lots for the allotment of spaces at noon, January 28. Manager Bonnell is now considering plans for decorations.

OHIO ASKS FOR GOOD ROADS MONEY

COLUMBUS, O., Dec. 13—State Highway Commissioner J. C. Wonders has filed with the State auditor estimates for the needs of the department for road improvement for 1910. He asks for $880,000, or $10,000 for each of the 88 counties of the State. He also asks for additional money for the employment of engineers. Last year the appropriation for road improvement was $5,000 per county.



Iowa Garage Built as Part of Side of the House to Save View of Mississippi River at the Rear

INTERIORS present a fertile source of discussion, principally for the reason that the ordinary person does not understand or else cannot read a drawing. So to these people the showing of a plan drawing means little. A photograph of an interior, on the other hand, may be read and understood by any one, to say nothing of criticising the arrangement of the interior there shown, which is an impossibility with the architect's floor plans.

For this reason the present instalment of the garage story will be devoted to interiors. These present the opportunity to bring out another feature of the garage, which in weather like the present—that is, in the winter time—is of unusually pertinent value. By this reference is had to the question of heating of garage interiors, whatever be the system.

Heating presents a number of problems, some of them dating as far back as the planning of the building in the first instance. By this is meant such a selection of size of building as to allow of the later installation of a heating system without reducing the available floor space to a too small amount, such a selection of materials and form of construction as will reduce the heating problem to its lowest terms, and such a selection of heating means as will call for the least amount of work attending to it, in company with a moderate installation cost, simple form of apparatus to reduce repairs, etc., to a minimum, and high efficiency.

Prevention of Freezing the Real Reason for Heat—Contrary to the common notion, the idea of heating a garage is not to keep it warm in the ordinary sense of the word, but to prevent the water in the jackets from freezing and the oil in the gearcase and crankcase from congealing. To this must be added the proviso that the chauffeurs' quarters be not an integral part of the garage. In that case the two parts must be differentiated between, for the driver and his quarters must be kept warm, while the car and its compartment need not be actually warm.

Typical Small Car Garage Interior, Showing Workbench

The various heating arrangements are as different as the many systems of heating of which the owner and builder has a choice. Speaking generally, it may be said, as of house heating, that there are four systems, with many, many variations and additions to them which constitute the make-up of perhaps a hundred different ones. The four principal ones are, however, unit or localized heating, in which a series of units such as stoves, fireplaces, etc., are used to heat certain units of localities; hot air, in which all rooms are heated from one unit, preferably a furnace; steam, in which system again a single unit of heat conveys warmth to all rooms, and lastly, hot water, which is like both steam and hot air in that a single source of heat is used.

Of course, some of the combination systems are of more than passing worth, and should not be dismissed with a word. Thus the method of utilizing steam or hot water in radiators to heat pure cold air, which is then circulated as a source of heat, is much used. Then the positive differential system, in which the steam supply to each and every radiator may be controlled accurately (this being a modification of the steam system), is very good.

Low First Cost Accounts for Many Peculiar Heaters—For the garage, on the other hand, most of these methods have the initial and apparently insurmountable fault of being altogether too elaborate, and consequently altogether too expensive. So the consideration of garage heating must start with something very simple and of low first cost. This accounts for the use of some peculiar heating methods as previously described.

Thus, in one of the previous issues a large garage was shown and described in which the only source of heat was a large open fireplace. This was, however, very large, provided with a capacious chimney to afford plenty of draft, and after several years' use has been found satisfactory for the heating of this particular garage, or at least sufficient to prevent the two Haynes cars owned from freezing up.

Another three-car garage, shown last week, has no other source of heat than a very big stove placed in the middle of the side of the garage floor. In addition to the car floor, this heats the chauffeur's floor above. The fire may be driven rather hard for the purpose of sending plenty of heat upstairs without actually heating the ground floor very much. But at that the heat should be sufficient to save the plumbing of the building and the water jackets of the three Thomas cars. No one stove, no matter how large.

could actually make this room hot, since it is 25 feet wide by 60 feet long, and liberally provided with windows to carry off the heat as rapidly as the stove can furnish it.

After a close investigation of the subject the writer is forced to the conclusion that the majority of garages are heated by means of stoves in some one form or another.

Use of Stoves Well Nigh Universal—These vary in size with the area of the garage and the attitude of the owner toward the matter of heat. Some owners—and it is a pleasure to state that their number is growing less each year—put the car up for the winter, thus losing the use of it for about four months. These owners, of course, know little and care less about the matter of heating, their interest being confined to drawing off the water when the car is put away and refilling it when the car is brought out in the spring.

On the previous page is shown the interior of a small one-car garage, which has been described and the exterior illustrated in one of the earlier numbers. This interior shows no heating arrangement, but some of the other features are worth calling attention to. The work bench, tool box, cabinet for clothes or spare material, and shelves for the same, may all be seen. It will be noticed that the place is lighted by electricity, one of the sockets serving as a place of attachment for the electric vulcanizer. This can be seen on the far end of the work bench. The bare spot between the work bench and the cabinet with doors at the left was left purposely, the idea being to place a small lathe there later on. It was the intention to drive this by means of electricity, the lathe being direct-driven from a small motor mounted upon an integral part of it and wound to use lighting voltage.

The lamp connection seen at the window would be used for this, so as to leave the present overhead light. At present the connection at the window is used for a portable lamp, allowing the use of the light wherever needed. Similarly, with the vulcanizer, the extension on that permits of using it on the tires, which need not be taken off the machine, but are vulcanized in place.

In the center of the floor the drain, and the slope of the floor sides toward it, give a hint of the washing methods, although the position of the camera was such as to fail in showing the source of water supply at the front entrance, or the entrance either.

Heat Supplied for House in Many Cases—As has been chronicled several times before, the heat may be supplied from the house heating system when the two buildings are sufficiently close together to make this a practical thing to do. When the garage and house are separated by a space of more than 25 feet this method becomes of doubtful utility, particularly in the case where the chauffeur's living quarters are included in the garage building.

In the issue of Dec. 9 the garage of squared field stone shown at the head of the article there was heated in this way, as was also the one shown at the bottom of the same page. Both of these were very close to the house and the source of heat, the former being within 15 feet at the point where the pipes were carried across. In the latter instance the distance was not as small as this, but was about 20 feet.

Cases like the one shown at the head of this article are few and far between, but at that the heating problem was an easy one to solve. In this case the garage was built as an integral part of the house, being the small square extension at the left, in front of which the car is standing. Aside from ease and certainty of heating and the apparent convenience of this location, the owner had another idea in locating the garage as the picture shows it.

This was the view from the rear. The Mississippi River flows past the rear of the house, the bluff upon which the house is situated being one of the banks of the river. With this idea in view the owner built a fine porch or veranda clear across the rear of the house, on which he could sit and view the river, with boats passing up and down. This fine view he did not want obstructed. So the garage had to be built at the side.

As built it has two doors, one at each end, closed by means of sectional steel blinds, which roll up out of the way like a window shade. By opening both the owner may drive through, turn around on the drive back of the house and come back through

Radiator in Plainfield Garage is Large and Prominent

towards the street. At the left side, there are two narrow but very high windows, which have prism glass to increase the amount of light furnished to the interior.

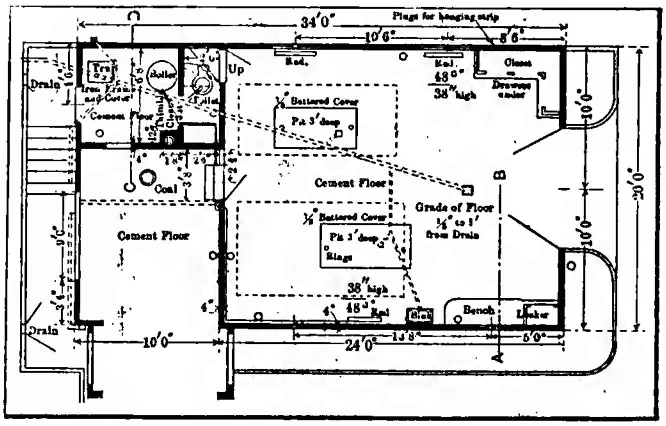
Heat is furnished to the garage interior from the steam plant located in the basement. Steam coils are placed along the side nearest the house. Since the garage is practically a part of the house, the heating offers no difficulties other than the ordinary plumber's pipe-fitting.

Interior of Garage with Superior Equipment—At the head of this page is shown a garage interior in which are to be seen a number of things in the way of equipment which have not been seen in any other garage pictured thus far. This building not only has a large pit, as the picture shows, but means for heating the whole interior adequately, a large-sized lathe, forge and anvil, drill press, electric vulcanizer, and many other little conveniences of value to the owner who has learned to do his own repairing.

Electric drive is utilized for the lathe, as well as all other tools, this being provided through the medium of the small motor shown in place on the bench in front of the lathe at the right. This lathe is also arranged to be run by foot-power should the owner so desire. The stoutly constructed bench carries the usual vise, and adjacent to it, in the corner, is the group of shelves, which are arranged to hold about everything used in ordinary repairs. This picture, portraying as it does but one corner of the whole building, shows but half of the full equipment.

It does, however, show the radiator used for heating purposes. This is an ordinary radiator of large size, suitable for either steam or hot water, the writer not being sure which method of heating is utilized. Other radiators placed in the middle of the other sides (except the front), the same as this one is in the center of this side, act together to warm the whole inside very thoroughly. The heat is more necessary in this case than in the ordinary one, because the owner does all of his work here.

Although long and fairly wide, the pit in the foreground has been so foreshortened in photographing that it looks very small. This is not the case, the appearances being misleading, for the pit



Plan of Two-Car Garage With Complete Heating Plant

Elaborate and Efficient Heating Plant in Paterson Garage

is slightly longer and somewhat wider than in the ordinary garage of medium size, say for two or three small-sized cars.

Electricity, of course, is used for the lighting, while the fire protection may be summed up in two words, hose and extinguisher. The former is not visible, but the latter (at least one of the latter) may be seen in the corner on the top shelf. This last-named is very important, since the building is a frame structure.

More Elaborate Heating System Shown in Plans—At the bottom of the same page is illustrated another garage, in which the heating arrangements are somewhat more elaborate. This one has living rooms above, so the heat furnished and the method of furnishing it must of necessity be more elaborate. As the plan shows, a whole room is given up to it, and another just outside of it to the fuel supply. A vertical boiler of large diameter supplies heat through pipes to three radiators on the car floor and two on the floor above. The three on the ground floor may be seen, one on the side nearest the observer and located close to the work bench, which is an excellent idea. The other two are placed equal distances apart on the other side, being actually located in front of the two windows on that side.

Many points other than the heating will be noticed here. The floor provides two pits, and one drain for washing purposes. Alongside of the bench and occupying the corner of that side with the front is a large locker. On the opposite side, also occupying the corner but much larger in size and capacity, is another locker, lettered closet in the drawing. This is a two-car garage, and built throughout of cement. The dotted lines across the floor show the drain pipes underneath the building, except in the case of the two pits. The dotted lines around these give some idea of the floor space which cars setting over the pits would occupy.

Perhaps the most ingenious thing about the whole garage is not noticeable in this drawing. This is the way in which the design provides several living rooms above, yet without going to the expense of carrying the building up to a second story. The ceiling of the automobile room is very high, but the ceiling of the open shed and boiler room is not; on the contrary, it is very low. This effects a saving in height, which, taken in conjunction with the space provided by the upward sloping of the roof at the center, makes a very large space. In fact, this space is large enough to give the chauffeur several rooms without skimping on them.

Frame Garages Require More Care in Selection of Heating

Small Hot Water Heater—The small cut on this page is that of an interior showing a small hot-water heating system now on the market. This is a special stove developed for the purpose, and, besides economy, has many good points. The stove itself has a deep, non-cleaning fire pot, circular in form and located within the one-piece base. The fire is entirely jacketed within the heater, so that none of the useful heat furnished by the fuel goes wrong. This in part accounts for the economy of the whole system.

Special shape of gratebars allow the use of any old kind of fuel, regardless of size or character. The complete system includes the radiator or radiators, small-diameter tank and smaller tank for the higher position, this providing assistance in the matter of water circulation through the action of gravity.

For heating, the upper tank is filled and the fire started. The water flows by gravity to the coils surrounding the fire pot, where it is heated. From there it proceeds to the circular boiler. This boiler acts as a source of supply from which the radiators are kept full of hot water. The vertically placed reservoir has no other function than to supply the radiators. In the whole system there are no valves or traps, the four parts of the apparatus being complete and self-sufficient when connected up by the plumber.

Compact Hot Water System

Reasons applicable to this outfit are equally applicable to many other hot-water systems, and, in fact, to nearly all fluid heating systems, including steam as a fluid. These are eight in number, as follows:

First—It will reduce the fire hazard to a minimum.

Second—It will eliminate the danger of freezing while in the garage of liquid-cooled cars.

Third—It will furnish hot water for cleaning purposes.

Fourth—It will last a lifetime.

Fifth—It will save you fuel.

Sixth—It will save you time and attention.

Seventh—It will reduce the repair cost on your car. You will have a comfortable place to work—the mechanism of your car will be kept better adjusted.

Eighth—It will keep your car looking better. You have hot water to clean the car—it will be done oftener and better.

One Garage's Very Admirable Heating Plant—One of the best and most complete heating arrangements for garage interiors which has come to the writer's notice is that pictured on this page. The strangest feature about this very complete and most admirable outfit is the fact that the car owned and kept in the garage is not a water-cooled machine, but an air-cooler, and as such not so susceptible to cold weather. Exception might be taken to this last statement on the score that air-cooled cars use more oil, and that, regardless of the cylinder cooling, the lubricating oil should not be allowed to congeal.

As is apparent, the furnace (its size makes that name necessary), located in an alcove so as not to reduce the actual floor space, supplies hot water to the radiators. The latter are arranged around the building, not at the floor line, but slightly above it. Their use is not restricted to any one side or part of the garage, but they are strung continuously around all sides, resulting in very efficient heating, and that, too, of a steady, even nature, so desirable in any heating system.

(To be concluded.)

POINTERS ON VALVES AND VALVE TIMING

By Arthur H. Denison

ADJUSTMENT and timing of the valves and the condition of their seats have much to do with the power developed by the gas engine. Cars that are constantly before the public, in racing and hill climbing events, have infinite care given to these details, and it is due to this care that races are won. The touring car, whether cared for by the owner or chauffeur, will give much better satisfaction, will develop better power and speed, with less depreciation and cost of upkeep, when cared for properly and kept in first-class order.

Valves are a necessity, in order that a suitable combustible mixture be passed into the cylinders, and the burnt products of combustion allowed to escape. Different forms of valves are in use, but in standard four-cycle engine practice, representing the great majority of American designs, the mechanically operated poppet valve, with either a flat seat or with an angle of 45 degrees is in use. Mechanically operated is not a strictly correct term, as the valves are merely opened by mechanical means and closed by the tension of a spring. If the spring is weak the valve will be late in closing. The springs in use on a modern high-speed motor vary greatly, but generally have a tension of about 40 pounds.

The cycle of operations of the engine is usually described as commencing with the suction stroke. A mixture of carburetted air—that is, air and hydro-carbon vapor—is forced into the cylinder through the inlet valve by atmospheric pressure as the piston travels downward on the suction or inlet stroke. At a point near the bottom of the stroke the inlet valve closes, and the piston, traveling upward, compresses the mixture to a pressure generally between 60 and 90 pounds. (Compressing the mixture enhances the value of the explosive pressure many times.)

Following the completion of the compression stroke, and the electrical contact that produces combustion, the piston is driven downward on the power stroke by the expanding gas. At a point near the bottom of the stroke the exhaust valve is opened, and the burnt products of combustion commence to escape. This valve is held open during the following up stroke of the piston. As the motor is developing power in but one stroke out of four, it follows that the most efficient motors are those that draw in and retain the greatest volume of gas on the suction stroke and get rid of the burnt gas with as little back pressure as possible on the exhaust stroke.

Gas Inertia Must Be Considered—All matter possesses weight, and one pound of air at a pressure of 14.7 pounds occupies approximately a volume of 1,488 cubic inches. It will therefore be seen that, possessing weight, it must, when traveling through the intake manifold and passages at speeds up to 10,000 feet per minute—some motors for racing work having reached a speed 50 per cent. greater than this—must possess a certain momentum or inertia that can be utilized to the motor's advantage.

When the piston is traveling at a high rate of speed, the gas does not flow into the cylinder the instant the valve is opened, nor can the column directly follow the piston head at its full density, owing to friction losses due to bends and walls of the passages. As some little time is necessary to start the flow, it is probable that the following is the actual condition of affairs.

In contact with the piston head is a region where there is practically no pressure, or approaching a perfect vacuum and above that a mixture of gradually increasing density, which at the valve probably would be at full atmospheric pressure. Were the inlet valve to close when it had reached the lowest point of its stroke, there would not be a mixture inside the cylinder that would fill it to near atmospheric pressure. One of the peculiar properties of gas is that it will always fill the volume it is contained in, regardless of the pressure, and the small charge trapped in the cylinder will have a lessened compression and explosive pressure value, thus affecting directly the power and speed of the car. In the manifold, the momentum of the column would cause it to ram against the head of the valve with an increasing pressure for an instant, then flow back out of that section of the manifold and disturbing carburetting conditions.

Timing Compensates for Gas Inertia—To take advantage of the momentum of the column of gas, it is customary to time the inlet valve to close when the greatest amount of gas is in the cylinders. The only accurate method of finding the correct valve timing involves the use of costly instruments in the engineering laboratory. When the piston passes the dead center, the crank shaft must travel quite a distance, measured on the crank circle before the piston has traveled an appreciable distance upward. Fig. 1 shows this, in crank-pin movements of 15 degrees.

General practice is to close the inlet valve 15 to 30 degrees.

After dead center, it having been found that the influence of the piston traveling up was, at the point where the valve closed, just sufficient to balance the momentum of the column of gas coming in through the inlet port. Any further opening of the valve would allow part of the charge to be pushed back out through the open port. It must be remembered that the valves are timed to give the engine the greatest power at a certain speed. When a valve opens or closes after dead center, as in the case of the exhaust valve closing, followed by the inlet valve opening, both are said to have a *lag* of "X" degrees. An exhaust valve opening before dead center has a *lead* of "X" degrees.

The exhaust valve is opened from 30 to 60 degrees ahead of the crank dead center. The drop in the pressure is very rapid during the first half of the stroke, after which it is not very effective as a means of developing power. Opening the valve before the dead center allows the gas to expand to near atmospheric pressure by the time dead center is reached and on the exhaust stroke, the piston has a comparatively small amount of gas to force out. Were all openings in the exhaust line to be stopped up, the pressure of the exhaust gas would become so great in a short time that the motor would stop. The exhaust valve closes at dead center or a few degrees after, taking advantage of whatever momentum is in the gas in order to carry out as much as possible. The opening of the inlet valve should follow very closely the closing of the exhaust valve, but both should not be open at the same time.

Manufacturer's Part in Correct Timing—When a car leaves the factory for delivery the motor timing gears and flywheel should be so marked that trouble will not follow if the

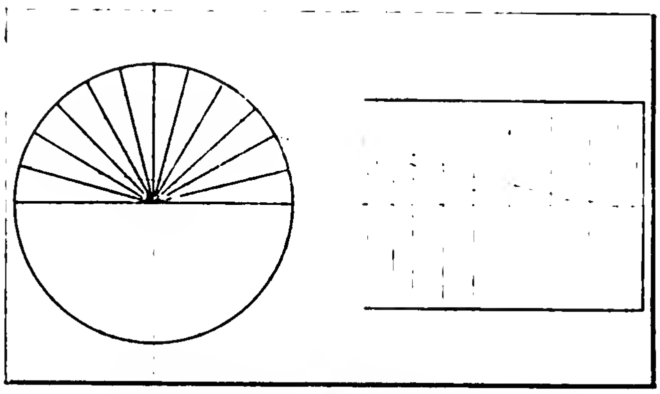


Fig. 1—Piston travel per 15 deg. crank pin travel

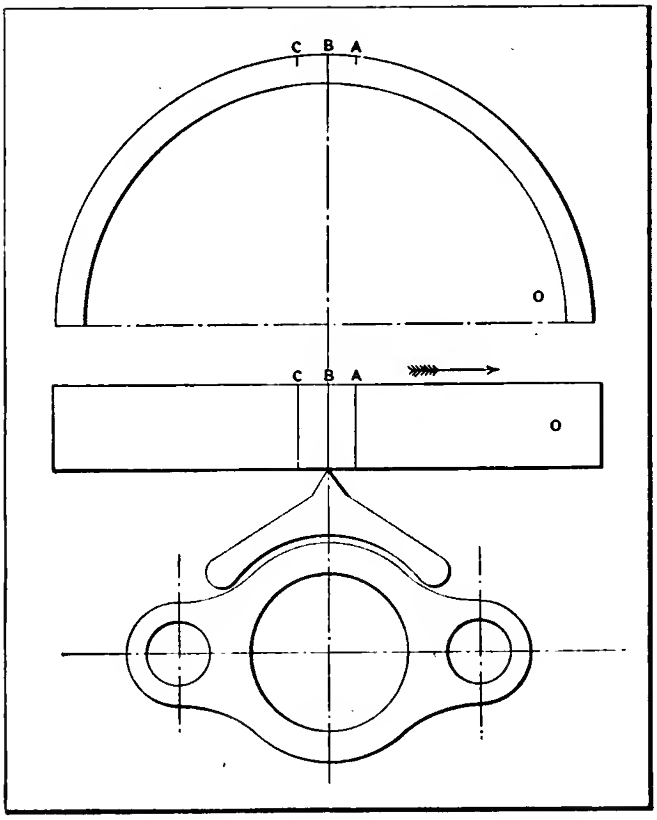

Fig. 2—Method of using indicator to time valves

gears are carelessly removed. Much of the trouble and dissatisfaction at repair and overhauling work is probably due to original valve timing by the mechanic who has been experimenting with gears that were not marked. There may be two, three, four or five gears in the timing case and all should be carefully marked, not with the nearest cold chisel or center punch but with a set of figures or letters. The tooth of one gear and the space of the one that it is in mesh with should be clearly marked with the same symbol, and that symbol used only once.

If there are two gears of the same size in the case as the magneto and pump shaft gears, and placed at opposite sides of the case, stamp the gear and shaft also to prevent getting them mixed up. Carelessness there may result in the gears being meshed otherwise than the way they have been fitted, and they may run noisy. If a gear is held with two keys, 180 degrees apart place symbol marks so that the gear can be readily replaced and the symbol marks coincide. Cam shaft gears may be bolted to a flange on the shaft, and both the shaft flange and the gear should be marked so that the gear can be readily replaced correctly. Were the factory to mark the gears thus, the multitude of scratches and marks often seen would not be needed, nor eccentric and original valve timing cause low powered or overheated engines.

How the Flywheel Should Be Marked—The flywheel should have the timing of all the valves and the head centers of the pistons plainly marked. The mark may be an arrow head or punch mark, and a light scratch should run across the flywheel, with the meaning stamped beside and reading, for example, "1 & 4 INLET OPEN," or "2 & 3 HEAD CENTER." The marks mean that when a pointer, usually placed in the center line of the motor, is pointing to that line that one of the valves designated is starting to open or close, or two of the pistons are at their head center or highest point. Fig. 2 illustrates and should make this clear.

When testing the valves for the points of opening or closing, it is sometimes difficult to determine the exact point at which the lifter is tight. A little clearance between the valve stem and the lifter allows for expansion and the valve to seat tight. If the valve lifters are not spring controlled, the least rattle or shake can be readily detected with the finger, or if this method is not practicable a cigarette paper is the thinnest piece of material to be had, and this may be placed between the valve stem and the lifter. When it is tight the valve may be considered as starting to open.

Correct Valve Lifter Clearance—Valve lifters should be set so that every valve stem has the same amount of clearance. One-thirty-second to 1/64th of an inch is generally sufficient, and more than this will make the motor noisy. A piece of steel or brass of this thickness may be readily obtained, and, placed between valve and lifter, will allow adjustments to be made quickly and easily.

If the motor gears are apart and gears and flywheel not marked, the following is probably the easiest method of replacing the gears so that the motor is timed right. First, place the piston of No. 1 cylinder on its head dead center. This may be found by running a wire through the compression tap or noting the position of the cranks, etc.

Consider a motor with a single cam shaft.

The first cam generally operates an exhaust valve, and this should close at or a trifle after dead center. The cam shaft should be turned until as near as possible in its correct position and then the gears meshed. If two cam shafts are used, one for the inlet and the other for the exhaust valves, the piston does not need to be moved, as the inlet valve must open a few degrees after the other has closed. Then measure the piston travel and find when the valves open and close.

Unless the cams have been removed from the shaft, it is safe to assume that, with the proper opening of the inlet valve and proper closing of the exhaust valve, the other points of operation for the valves are correct. If the exhaust valve closes either at head dead center or within an inch and a half after, and the inlet opens right after the exhaust closes or within a distance of not more than two and one-half inches past the dead center mark, the valves may be assumed to be correctly timed. The measurements are made on the rim of the flywheel, and the above figures are for large-size flywheels.

How a Timing Diagram Is Laid Out—When considering the power output of a motor as low and due to defective valve timing, the flywheel is not marked, and the marks on the gears unreliable, the best thing to do is to make a diagram of where the valves are actually opening and closing. With a compass lay out a circle, of any convenient diameter to represent the rim of the flywheel, and draw the vertical diameter, which will represent the head centers. With whatever means practical find out the time of the inlet valve opening.

Suppose it opens one-quarter of an inch after the piston has passed the dead center and is traveling downward. If the stroke of the motor be considered as five inches this would be 1/20th of the stroke, and measured in degrees 180/20, or nine degrees. With a protractor lay off nine degrees on the circle past the dead center point. Then take the point of inlet valve closing, and suppose it to be one-half inch after the lower dead center. This would represent 18 degrees, and lay this off on the circle in the same manner. Then treat the opening and closing of the exhaust valve in the same manner, and the result would be a diagram like Fig. 3.

Here the exhaust valve has been supposed to open one inch before the lower dead center and to close one-eighth inch past the upper dead center. A glance at the diagram will show that the motor is timed correctly, according to the principles of valve timing. Were the gears meshed one tooth off, it would affect the time about three or four inches on the flywheel rim. Either the exhaust valve would close before center, thus retaining a certain amount of the dead gas and weakening the mixture, or if it closed that amount late, it would likewise open late and make the motor run much hotter, as it would be subject to the heat of the gas for a longer time. The inlet would remain open so late that part of the gas drawn in would be pushed out through open port when the piston should be compressing the gas with the valves closed. Or on the other hand, it would close too early, which would result in a scanty charge being drawn into the cylinders. In actual latter-day practice, the inlet is held open a small amount of the compression stroke, so as to take advantage of the inertia of the inrushing gas, this being sufficient to overcome the slight compression effect produced for the initial 5 or 10 degrees of crank movement past the lower dead center. In some modern engines, this lag of the inlet valve amounts to as much as 40 deg. and more. Thus, Peugeot uses 58 deg., Panhard 45 deg., and De Dion 45 deg.

Why Exhaust Needs Grinding More Often Than Inlet—Exhaust valves, in particular, generally require frequent grinding in. It is a common practice to slow the motor when the car is stopped by closing the throttle and retarding the spark as much as possible. This allows ignition to take place after the piston has passed dead center, and the gas burns slowly, both exposing more of the cylinder walls to the great heat, and also retaining most of its heat till the exhaust valve opens. Thus both the valve and its seat are subjected to a temperature almost great enough to melt the iron were the heat applied continually.

Intermittent bursts of flame serve to warp the valve and make the task of grinding it to a tight fit one of great difficulty, or the valve may be too far gone and a new one needed. Valves may be ground in with emery or carborundum floor and oil, or one of the many preparations on the market for this purpose. A soft lead pencil or a little blue will serve to test the bearing of the valve on its seat. The valve should be ground to hold gasoline.

Valve springs may lose their temper and fail after long use, causing the motor to be sluggish. A good test is to place a washer under the valve spring, thus materially increasing tension.

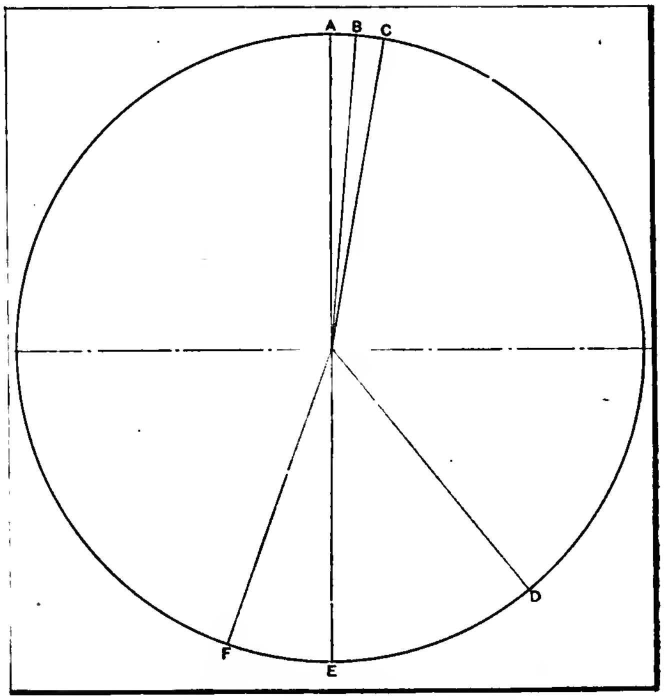

Fig. 3—Principles of valve opening and closing

OIL CONSUMPTION IN THE FRENCH COMMERCIAL TRIALS

By W. F. BRADLEY

PARIS, Dec. 9—Speed, reliability and simplicity are features that have been very closely studied in the modern automobile, but comparatively little attention has been paid to economy. This is doubtless due to the fact that the greatest development of the automobile has been as a pleasure vehicle, the owner of which, although keen to get the greatest value for his initial outlay, pays little attention to the daily and comparatively small expenditure for gasoline and lubricating oil. There are not many owner-drivers who can state off-hand the mileage per gallon of their cars, and still fewer who know exactly how many miles they can run with a pint of lubricating oil. It is only necessary to see the pools of oil left by most cars after standing to realize that the owners and manufacturers are often as careless as they are ignorant on this point.

Even in Europe, where the high rates of gasoline and greater price of lubricating oil, compared with the United States, leads to greater economy in their use, the matter has not received anything like adequate attention. Lubrication methods, however, are far from being perfect, as can be judged from the official results in the recent French commercial vehicle trials. For the first time in any competition an accurate control was maintained on oil and grease as well as on the various fuels used. The test was a really practical one, for it was spread over a period of thirty days and for a road distance varying up to 2,000 miles.

The small number of entries makes it impossible to draw any general conclusions except in one class, devoted to trucks carrying a useful load of between two and three tons. Without entering too closely into figures, it may be stated that the actual load, exclusive of tools and spares, was in every case only a few pounds short of three tons. The vehicles made twenty-four journeys, over various kinds of roads, and under varying weather conditions, the total distance covered being 1,794½ miles.

The best performance was made by a four-cylinder Saurer, which, during the month, consumed 37.7 pints of lubricating oil and 2 pints of grease. This means that 47.8 miles were covered for each pint of lubricating oil. In the official table the grease consumption is, curiously, given in pints, instead of in pounds. This item, however, can be ignored, for in every case but one the consumption did not exceed 3 pints for 1,794 miles.

Thirteen vehicles are included in the official table, these having gone through the month's trial with a clean score so far as regularity is concerned. The average oil consumption was at the rate of 1 pint per 16.4 miles. The Saurer, which held the record with 47.8 miles on a pint, and incidentally won first prize for all round economy and efficiency, was followed by a duplicate vehicle with 34 miles to a pint. A De Dion was also very economical with 25.4 miles to a pint of oil. A two-cylinder Delahaye, which obtained second prize on formula, running the Saurer very close, evidently lost first prize entirely to neglect of economy in lubricating oil. It was the most economical in fuel, whether it was gasoline, alcohol or benzol, but it required a pint of lubricating oil every 12.9 miles.

The value of the test is shown by the fact that whenever there are two similar vehicles from one factory their oil consumption was practically the same, thus showing that it was a test of systems, and not a mere exhibition of the ability of the driver skilfully to economize without risk to his motor and transmission. The test also proved conclusively that constructors had not paid sufficient attention to economical lubrication, otherwise we should not see differences of over 100 per cent. under identical conditions of operation. The following table sets forth the amount of oil consumed for a total distance of 1,794.5 miles and gives the mileage obtained on a pint of lubricating oil. The vehicles were run at an average speed of not less than 9 nor more than 15½ miles an hour.

	Total Miles	Oil in Pints	Miles per Pint
Saurer, 4-cyl., 4.3 by 5.5 ins.	1794.5	37.7	47.8
Saurer, 4-cyl., 4.3 by 5.5 ins.	1794.5	52.8	34.0
De Dion, 4-cyl., 3.5 by 3.9 ins.	1794.5	70.4	25.4
Vinot, 4-cyl., 4 by 5.5 ins.	1794.5	107.2	16.7
Aries, 4-cyl., 3.3 by 4.3 ins.	1794.5	132.0	13.5
Delahaye, 2-cyl., 3.9 by 7.08 ins.	1794.5	135.5	13.3
Delahaye, 2-cyl., 3.9 by 7.08 ins.	1794.5	139.0	12.9
Peugeot, 4-cyl., 3.5 by 4.7 ins.	1794.5	140.8	12.7
Vinot, 4-cyl., 4 by 5.5 ins.	1794.5	149.6	11.9
Aries, 4-cyl., 3.3 by 4.8 ins.	1794.5	161.9	11.08
Panhard, 4-cyl., 3.5 by 5.1 ins.	1794.5	241.2	7.4
Malicet & Blin, 4-cyl., 3.5 by 4.7 ins.	1794.5	260.5	6.8
Cohendet, 2-cyl., 5.7 by 5.7 ins.	1794.5	602.18	2.9

AN INEXPENSIVE HOME-MADE ELECTRIC LIGHTING SYSTEM

By VINCENT B. MINER

BECAUSE of the antics of a poorly designed kerosene rear light, which would stay lighted only with the flame at a ridiculous height, the writer was moved to plan the installation of an electric light at this important point. The idea expanded in its execution to include the two sidelights, also of the kerosene species. It may be well to mention that this system was not intended to replace headlights or searchlight (which would have greatly increased the cost on account of expensive parabolic reflectors), but was intended to supersede the ancient, dirty, uncertain and weak battery of kerosene lamps. As it was a total experiment, so far as the writer was concerned, the expense was to be somewhat limited. As a result of careful simplification, the cost of the complete outfit was kept at $2.91, and the time to install at half a day. Retail prices were paid for everything; and, with the possible exception of the lamps themselves, each article was standard and easily obtainable at any electrical supply store.

Almost any low-tension direct-current or alternating-current generator designed for ignition purposes in conjunction with a vibrator coil, or a six-volt storage battery, will suffice for this system, and their possession is presupposed. The description and directions which follow are intended for those who are using the generator; for those who possess a storage battery only the sole difference would be to tap the wire leading from the storage battery to the coil, instead of the wire leading from the generator to the coil. The writer is using a Western-made, belt-driven mechanically-governed, direct-current generator, which keeps all lights brilliant, even at the lowest possible engine speed.

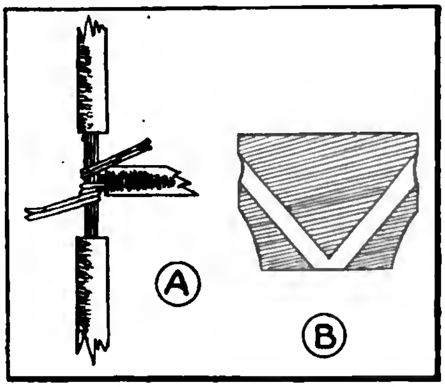
Purchase the following:

3 6-volt 6 candle-power anchored filament tungsten lamps, minimum base	$1.50
1 single-pole porcelain-base snap switch	.20
3 miniature receptacles, porcelain base (depending upon oil-lamp body)	.21
8 feet ¼-inch internal diameter flexduct	.48
3 porcelain cleats (to fit large wire)	.10
1 small can paint (color of car)	.10
12 feet No. 14 D. B. stranded wire, rubber-insulated ("large wire")	.16
6 feet No. 22 S. B. rubber-insulated copper wire ("small wire")	.06
Screws for cleats, switch, and receptacles (fit each) about	.10
	$2.91

The desired position of switch on the dash is first selected, after which the generator wire to the coil is tapped at the nearest or most convenient point to this switch. At this spot about an inch of insulation should be removed, also the same amount from the ends of the large wire. Make the joint as shown in sketch A. After taping thoroughly run this wire over to the switch location and cut, allowing sufficient to go up through the switchbase and connect on the switch terminal. Connect this wire to one switch terminal. Connect one end of the remaining large wire to the other switch terminal, being certain that switch is turned off. Now firmly screw switch to dash at previously determined point. It will now have to be decided whether the wire from switch to sidelights is to run across the top or bottom of the dash.

Cross Wire on Dash, and "Flexduct" Coming Through Floor

Estimate the distance from the switch to the proposed line across the dash, allowing an inch or two over, and at this point cut the second wire leading from the switch. We are now ready for the dash wire leading to the two sidelights. Run this a little out beyond the dash on both sides, having each end leave the dash as near as possible to its respective lamp. Where the dash is surrounded by a dash hood it is necessary to bore holes through same at points near the lamps for the passage of this cross-wire. Be sure to tape the wire well where it runs through these holes, so as to prevent the insulation from chafing. Now secure this cross-line with one cleat placed about the center of the dash. Tap the cross-wire at a point nearest the switch, connecting the short wire from the switch thereto, as illustrated in sketch A. With the aid of two more cleats firmly secure this cross-wire all along the dash.



Sketches of Wire Connection and Plug

We are now ready for the rear-light line, which taps this dash cross-wire, running through conduit to the rear light. Bore hole slightly larger than the conduit in rear end of body at a point exactly opposite the rear lamp. Bore a similar hole in the footboard nearest the dash at a point nearest where it is desired to tap the dash cross-wire. Suspend the conduit along the frame or body, whichever seems most expedient, thrusting the ends through the previously bored holes—the rear conduit end being flush with the rear of the body. Now lash conduit securely to frame by means of very heavy tarred twine or tire tape, or secure it by means of a few U-shaped metal straps. Cut off any surplus conduit which may show at the dash to a point about one inch above the footboard and mat. Run the large wire through the conduit, starting from the rear end. Tap dash cross-wire at point of intersection with this rear conduit wire, as shown in sketch A, and cut at rear end, allowing about 2 inches to project for connection purposes.

Now Ready for the Lamp Connections—Upon attempting to give directions for the successful and easily performed installation of electric lamp receptacles or sockets in the former oil lights, the writer is confronted with the widely varying types of oil lamps now in use. At no part in the construction of this system is it possible to use more ingenuity than in the adaptation of the small porcelain receptacle or socket to the available apertures, or lack of same, in the oil lamp. If the reader has an oil fount and burner which is removable as a unit, as has the writer, he has a "cinch," for the hole left by its removal is a quick way out of possible trouble. However, the writer's rear light has a permanent wick guide or holder, which necessitated an entirely different method of treatment.

First, the sidelights. When the fount and burner unit is removed it leaves a circular hole. Two wooden plugs of slightly larger size than the lamp aperture are tapered down to a diameter slightly smaller than the aperture, the top of the plug being flat to accommodate the receptacle, thus (B). This may best be done in a lathe, but can be easily whittled instead. The reader will now find that these plugs will fit in the lamp apertures very tightly—no amount of rough driving will jar them loose. Two holes are then drilled in each plug diagonally, starting from opposite sides of the plug above the tapering portion to the center of the bottom, these holes being slightly larger in diameter than the small wires (see B). Paint these plugs to correspond with the color of the car, at the same time painting the porcelain cleats holding the dash cross-wire. After drying attach the porcelain receptacles to the tops of the plugs with small screws, taking care that the two terminals of the receptacles correspond with the two side holes of the plugs. Now measure distance from end of dash cross-wire to one terminal of receptacle when plug is in place in lamp. Allowing a little for connection and slack, cut off this amount of the smaller wire; attach one end to receptacle and thrust other end through diagonal hole, out through base of plug.

At this stage it must be determined what part of the dash is to act as the "ground," or return circuit. As shown in the photographs, the writer's car has a brass bead completely around the edge of the dash, which forms the best possible kind of a conductor. The screws used to secure this bead to the dash are made to act as the binding posts for the ends of the return wires from the respective lamp plugs. Practically all cars now have metal dash hoods which serve the purpose admirably, it being merely a matter of the owner's desire as to just how he wishes to connect his second or return wire from each lamp to the metal conductor. The rear lamp connection can be secured to the frame at some convenient nut or fastened in some secure manner to the body, if the latter be of metal. Boring two small holes 1-2 inch apart and looping wire through them is a satisfactory method. Measuring distance from lamp receptacles to point of ground, connect these two points, also connecting the end of the dash cross-wise with the first small lamp wire. Take care to tape all connections. We are now ready to connect our "ground" dash bead, dash hood or body to the frame (to complete the electrical circuit), unless this be already done by bolts. Do this by means of a piece of the large wire running from one of the above-mentioned grounds to the frame. The photograph shows clearly how the writer accomplishes this object; the invisible end being connected to a transmission bolt. On many cars this job will be unnecessary and may be left until the last, as a test with a set of dry cells will quickly disclose the presence of an established connection or the lack of it. Our wiring is now complete.

Place the lamps in the receptacles, taking care to screw them up quite snugly. Now cut about 10 inches of tire tape in half, lengthwise. Wrap this tightly about the base of each lamp and top of its receptacle, securing the end on the plug. This is to prevent the lamp from jarring loose. After the writer had first installed this system he was made painfully aware of the insecurity of the plain receptacle thread by hearing the electric bulb dancing around the lamp body. This treatment, incidentally, never feazed the anchored filament of the lamp.

Now for the test. Start engine, turn coil switch to generator (or storage battery), and turn on light switch. If lights fail to burn, go over the whole wiring for a loose connection. If there is a short-circuit the engine will stop when the coil switch is turned from starting battery to generator (or will fail to start in the case of a storage battery). If only one or two lamps burn, the remedy for the remainder is obvious. Up to this point an alternating-current generator is as good as one giving direct current.

To the above system used in connection with a generator there is only one genuine objection: no light when the engine (therefore, the generator) is at rest. If the owner runs his machine off the road into a yard or enclosure while not in use away from home, the above objection fails to hold. Otherwise (and in the great majority of cases) some permanent source of current is indispensable. Therefore, enter the storage battery and, correlatively, the direct-current generator. Upon inspection of one of the photographs the reader will notice a second switch—of the indicating variety. One side of this switch is connected directly to the generator, the other taps the light line between the coil connection and the light switch, thereby controlling the connection between the generator and the coil. From this generator or coil connection runs a second wire to the battery box, wherein the writer intends shortly to place a storage battery, the second connection of the storage battery being grounded on the frame. Thus, the second switch controls also the connection between the generator and the storage battery. So wired, either the storage battery or the generator may be used for ignition or lighting, or both. Or the generator may be switched against the storage battery, thus, during day-time running, charging the battery. In this case be sure to turn off the second switch before stopping the motor, otherwise the storage battery current would short-circuit through the generator, demagnetizing the fields of the latter, and discharging the battery. This extra switch and wiring raises our total cost to $3.22.

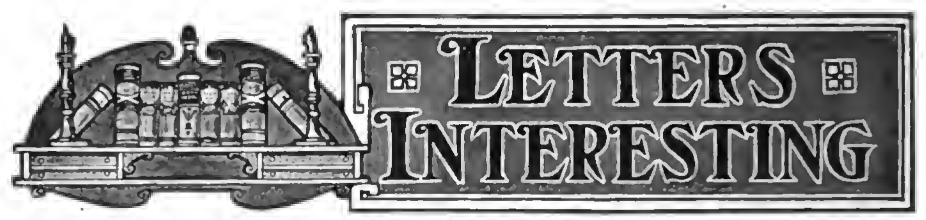
Dashboard with Extra Switch for Battery Connection



HOW TO DESIGN AN ENGINE

Editor THE AUTOMOBILE:

[2,117]—Will you please answer the following questions relative to a gasoline engine in the columns "Letters Interesting, Answered and Discussed?"

1. (a) At what point in the stroke does the gas attain a maximum pressure; (b) What is this pressure in pounds per square inch; (c) what is the temperature in degrees Fahr.?

2. (a) What proportion do temperature and pressure of exhaust gas in a water-jacketed exhaust pipe bear to the above mentioned temperature and pressure, i.e., in what proportion does it decrease?

3. What proportion of its volume will water absorb of burnt gas?

4. (a) What is the density of the proper mixture of gas before entering the cylinder; (b) after explosion and when exhaust port is opening?

5. (a) To what volume would exhaust gas from a single cylinder 4 in. by 5 in. motor expand before being reduced to atmospheric pressure if exhausting into open air; (b) if exhausting into an enclosure?

I am working on a single cylinder 4 by 5 motor and trying to incorporate new ideas.

Birmingham, Ala. E. V. SMITH.

Your questions are rather broad and it hardly seems fair to take up the space in the paper to tell you how to design an engine, or to go into the deeper and more abstract features about which you ask, but we will try to give you an answer.

1. (a) The gas attains its greatest pressure at the time of explosion, this time varying with the speed of the engine and the amount of lead given the spark. It varies from 30 deg. before dead center to about 20 deg. after, both being measured upon the crankcircle.

1. (b) No hard and fast rule can be given, which is not very involved. Four times the compression pressure is about right. 75 lbs. compression will yield 300 lbs. explosion.

1. (c) The temperature varies with the pressure and volume, the equation involving volumes and temperatures being:

$$T_b = T_a\left(\frac{V_a}{V_b}\right)^{\lambda - 1}$$

in which T_b is the temperature at the end of the expansion, assuming this to be adiabatic expansion

T_a is the temp. previous to expansion.

V_a is the volume previous to expansion,

V_b is the resulting volume, and

λ is the ratio of specific heats, this being taken as 1.35 for adiabatic expansion.

Barring only the value of the exponent, this same equation answers also for the compression stroke, the figures for that not having been determined very accurately. The same figure may then be used for the sake of immediate computation. If then, T_a be taken as atmospheric pressure (counting always the absolute temperature), the equation assumes the working form of:

$$T_b = 529\left(\frac{V_a}{V_b}\right)^{.35}$$

Using this, for your purpose, you have but to substitute the initial volume of the cylinder contents and either the final volume or temperature, to obtain the other.

In case it is more useful to you to have the relation of pressures than temperatures, the equation is:

$$P_b = P_a\left(\frac{V_a}{V_b}\right)^{1.35}$$

By substituting in this any known volume of the gas on the expansion stroke, the pressure at that time may be figured. This answers questions 2 (a), 5 (a) and 5 (b).

Your other questions as to absorption of gases by water and density of mixture would call for too much space, going as they do deep into the realm of chemistry. In the former case the amount of absorption would vary with the composition of the exhaust gases, which in turn will vary with the composition of the original mixture and the amount or completeness of the combustion. As to the latter case, question 4 (a) and 4 (b), both densities vary with the chemical composition of the gases at those two points as well as their temperature at that time.

All these questions and many more you will find discussed in great detail in the many excellent works on the subject of gas or gasoline engines, among which may be mentioned: The Gas Engine, F. R. Jones; The Gas and Oil Engine, by Clerk; Gas Engine Design, by Lucke; The Gas Engine, by Hutton, and a new book, Carburettors, Vaporizers, and Other Fuel Vaporizing Devices. Any or all of these may be obtained from The Class Journal Company, 231 West Thirty-ninth street, New York City.

USE AND ABUSE OF GRAPHITE

Editor THE AUTOMOBILE:

[2,118]—Will you kindly advise through the columns of your esteemed publication, whether or not it is considered good practice to sprinkle powdered or amorphous graphite on the wearing surfaces of bevel gears and transmission gears for the purpose of polishing same and filling microscopical indentions in the gears. Also kindly advise whether or not it is considered good practice to mix graphite in with other lubricants for transmission or bevel gear lubrication. If so, will you kindly give me a good formula for such a mixture? Kindly advise what steps can be taken to reduce the noise of the gears to make the car run absolutely noiseless. There is a certain kind of hum which seems to be in transmissions, which I should like to eradicate if possible. The car I have in mind is equipped with Timken rear axles, with pressed steel housing, and Cotta Transmission. F. W. B.

Dallas City, Ill.

Yes, this is good practice, although it is something which is seldom done. When graphite is used with other lubricants, the amount utilized is very small, thus, with oil, one tablespoonful of graphite to one pint of oil used. Similarly, with grease a tablespoonful to about 2 pounds of grease would be plenty.

In last week's paper, you will find in answer to a letter (2,110) that boxwood saw dust and heavy grease or sawdust in graphite makes a very good noise deadener for gear boxes. It is doubtful if all noise can be eliminated.

HIGH AND LOW COMPRESSION

Editor THE AUTOMOBILE:

[2,119]—Will you kindly answer the following questions in your "Letters Interesting, Answered and Discussed?" Which is best for high speed work or racing, a moderate compression of say 65 to 70 pounds or a high compression of 110 or 115 pounds? Why is it that automobile manufacturers do not put heavier flywheels on their engines so that they would run steadier at slow speeds? It seems to me that if they would put on heavier flywheels there would never be any need for more than four cylinders. Also, I would like to know how pure castor oil would be for the lubrication of the cylinders of an automobile, nearly all the oil men tell me that it will not do, as it is a vegetable oil, and that it takes a mineral oil.

Great Bend, Kan. A SUBSCRIBER.

For several years the compression pressures in general use continued to increase until they reached a figure of about 90 pounds in ordinary touring cars, and many pounds higher for racing cars. This pressure was found to have so many disadvantages that it was but a very short time before the backward movement began, and is still continuing.

To-day, the tendency is to use a fairly low pressure, or what would have been called low several years ago, say about 60 pounds. This results in an engine which anybody can crank without first arranging for the coroner and undertaker, as was the case with the higher pressures. Not only that matter of personal convenience, but the higher compression resulted in higher explosion pressures, which in turn acted to tear the motor apart with great rapidity. So, it came about that the higher compression motors were not only dangerous to crank, but very costly to operate as well, the repair charges being very high.

Flywheel weight is dead weight, which makers are very doubtful about the utility of, this being added to the dead load on the tires without enough advantages to compensate for it. Thus, with a very heavy, say unusually so, the tire wear will be about double what it is ordinarily. The question then arises if the additional weight is worth that much. We grant you, however, that a moderately heavy flywheel is all right, but believe that nearly all makers are using that kind.

On the subject of castor oil, you are referred to the discussion, which was printed in these columns some time ago, about five months ago, to be exact. Both sides of the perplexing question were then taken up, and discussed exhaustively.

To be exact, letter 1,948 in the July 22 issue started the discussion, this being favorable to the use of castor oil. Following that, in the Aug. 19 issue, there was published a letter from the Joseph Dixon Crucible Co. denying the benefits of its use, and advocating graphite as superior.

MAKER'S OPPORTUNITY

Editor THE AUTOMOBILE:

[2,120]—I am looking for a 1910 two-seated roadster, about 24 to 30 horsepower, weight about 1,600 pounds, road clearance say 10 to 12 in., body set low, 110 to 112 in. wheelbase, selective type of gear shifting, cost from $1,000 to $1,500. Can you put me into communication with the manufacturer of such a car? MAC.

New Rochford, N. Dak.

From the tables published last year at the time of the New York show in THE AUTOMOBILE, we have selected the following cars which seem to meet most of your requirements. Others are invited to write us and the name of this party will be furnished.

Overland ...	$1,250	25.6 h.p.	100 w.b.	1,800 wt.
Kissel Kar..	1,350	30	107	2,000
Cameron II..	1,500	36	112	1,600
E-M-F 30...	1,250	25.6	106	1,800
Chalmers 30.	1,500	24	110	.....

Of these the Cameron is of higher power than you want, being a six-cylinder, but is given on account of meeting the weight requirement so closely, this being the stumbling block in your case. The changes for this season are: Cameron, wheelbase to 114, and weight to 1,675; Chalmers, power to 25.6, and wheelbase to 115.

Following is another list of 1910 cars, which in addition to the above, seem to meet most of your requirements:

Black Crow.	$1,200	24.0 h.p.	107 w.p.	.....
Clark	1,400	25.6	110	.....
Illinois	1,250	25.6	107	2,000 wt.
Jackson	1,250	25.6	105	1,950
Johnson	1,500	28.9	112	2,200
Marathon ..	1,500	28.9	112	.....
Maxwell	1,500	28.9	108	2,500
McIntyre ...	1,250	27.2	112	.....
Middleby ..	1,250	25.6	108	2,200
Mitchell	1,100	28.9	100	.....
Moline	1,500	25.6	110	.....
Moon 30 ...	1,500	28.9	...	.....
Overland ...	1,400	28.9	112	2,200
Parry	1,285	28.9	*114	.....
Regal	1,250	25.6	107	1,900
Reo	1,250	25.6	108	.....
Rider-Lewis.	1,050	25.6	100	1,700
Everitt 30...	1,350	25:6	110	.....†

*Prob. †Clear. 11½.

SUGGESTS NOMENCLATURE

Editor THE AUTOMOBILE:

[2,121]—Isn't it time for some linguistic genius to arise and offer a suitable set of names for magnetos and magneto systems by which the present confusion and lack of accuracy might be avoided? Imagine a school teacher (automobile school, of course) asking his pupils to define a "high-tension" magneto. It is said that grocers classify the staple product of the hen into fresh eggs, strictly fresh eggs, and "just eggs." In the same way we have the high-tension magneto, "true high-tension magneto," and the plain "magneto," which usually satisfies the novice.

The trouble appears to arise from the fact that, while the spark ultimately produced is of the high tension variety in nearly all cases, the magneto in which the impulse originates may be either high or low tension. What the user is mainly interested in is the spark rather than the magneto, since the latter is only a means to the end. Consequently, when asked what ignition system he has or desires, he replies "high tension," as if that ended the matter.

To those in the trade, however, the matter is not so simple. Distinction between types is necessary, and it does not seem more reasonable to describe a magneto according to the ultimate spark than it would be to name the style of carriage according to the breed of horse that happened to pull it.

A magneto containing within itself the elements necessary for producing a high tension spark is fairly described as a high tension magneto, and its makers should not be driven to such verbal shifts as "arc light," "arc flame," or the prefix "true" to indicate his meaning, any more than the automobile builder should be required to prefix "actual" before his horsepower rating.

The real need seems to be for some phrase to describe the type of low tension magneto whose current is delivered to a step-up coil and there transformed to high tension. To call it "low tension" without explanation is impossible, and "low tension with separate coil" is equally so. Why not simply name it the "coil type" magneto, leaving the jump spark to be inferred? Belt driven magnetos having separate coils could then be described as "non-synchronous" magnetos.

A similar need exists for verbal distinction between the various dual, semi-dual, and hemi-demi-dual systems now on the market. Probably at least half a dozen could be counted, ranging all the way from that using the same interrupter, coil, distributer and plugs in both systems up to the only real dual system having the magneto and battery circuits entirely separate, even to the spark plugs. The weight of practice seems to be divided between the real dual system and the system which uses the same distributer and spark plugs, but with separate interrupters for the two circuits and a special coil for the battery circuit. The writer confesses himself staggered by the problem of finding a name even for the second of these two, but some one ought to find it, and when found it ought to be adopted.

New York City. HERBERT L. TOWLE.

CONCERNING WING TIPS

Editor THE AUTOMOBILE:

[2,122]—I am much interested in aeronautics, and have been reading your articles right along. However, I am puzzled to find what you mean by wing tips, and can find nothing about them. I would like you to advise me as to how to get information.

ANSON BILGER.

Oakland, Cal.

To use what may seem a Hibernicism, a wing tip is the tip of a wing. More exactly, it is the outer portion, say about one-third, of the supporting planes of an aeroplane. These outer portions, or tips, differ from the rest of the supporting planes in being flexible. The planes are inclined to the horizontal at an angle of from 5 to 10 degrees, and this angle is fixed according to the judgment of the designer. The tips, however, being flexible, can be set at will at either a larger or smaller angle. A larger angle means a greater lifting effect, although involving at the same time greater resistance to forward movement through the air. If a sudden current of air causes the aeroplane to tilt to one side, the aviator sets the wing tip (or tips, according as the machine is a monoplane or biplane) on the lower side at a greater angle, and decreases the angle of the tips on the side which the current is lifting, and thus brings the machine back on a level keel. In the Wright machine this feature is the subject of a patent, which seems to cover all forms of the warping (as it is called) now in ordinary use on aeroplanes.

TROUBLESOME CARBON

Editor THE AUTOMOBILE:

[2,123]—Kindly publish under "Letters Interesting, Answered and Discussed" your idea of the cause and remedy of the following trouble:

My four-cylinder Winton XIV is fed to the cylinders equal amount of oil as the sight feed would indicate. The oil is cut down as low as safety will permit.

The car after the first two or three minutes will run nicely, without a miss all day long. The plugs in cylinders 1 and 4 will be clean and the cylinders themselves free from carbon but 2 and 3 become very much sooted and considerable deposit of carbon is found in those cylinders. The carbon after letting the car stand a day or so is almost as soft and wet as heavy grease. Can you give any solution why 1 and 4 should be clean and free from carbon and 2 and 3 full of it, and why is the carbon wet instead of hard as in other cases?

Is there anything in Prest-O-Lite decarbonizer which counteracts the firing of a gasoline mixture? I used the cleaner in my car, and it worked beautifully as far as getting rid of the carbon was concerned, but believe me it was two whole days, working on and off, before I could get an explosion in the cylinders. The cylinders had the appearance of being smoky or foggy, so that you could not see an object one-fourth of an inch below the surface. This mist remained in the cylinders for nearly two days, and not until it disappeared could I get the engine to start. F. H. T.

Newark, N. J.

It is just barely possible that the pipes to the sight feed are slightly clogged up so that all of the oil that flows is not indicated there. In that case, you would be feeding much more oil to your cylinders than the sight feeds indicated, and than was desirable. First thing you do, clean out these pipes, so that you may be sure that the sight feeds are honest, that is, indicating all of the oil that is flowing.

Finding that all right, there is the possibility that your carbureter is set to give too rich a mixture at slow speeds, before the auxiliary air valve opens. This would account for the formation of carbon at those times, but it is impossible to account for its being soft and wet like heavy grease as you describe it. This is something of which we have never heard before, as all carbon deposits seen or heard of have been very hard and brittle.

In finding the carbureter in proper shape as well as the oil piping, look to the fuel you use. Much of the fuel to-day is of very low grade, and some bought from unscrupulous dealers may even be doctored. This could only be done with some substance cheaper than gasoline, and the soft mass left in the cylinders might be that residue from the fuel, carried a little at a time into the cylinders, where it collected.

As to the decarbonizer, the exact chemical composition of it is unknown, but it is believed to contain kerosene in a large amount. This would not cause the trouble you speak of, nor would any known mild acid, which might be used for this purpose. It would be advisable to seek the advice of the manufacturers of this substance. They would be able to help you, and glad to do so.

Although the use of decarbonizer is strongly advocated by the makers, it does not seem to have struck the note of popular favor as yet, and your correspondence with the makers might be of interest as shedding light on the situation.

WOODS' ELECTRIC MAKES CHARACTERISTIC PROGRESS

Fig. 1—Coupé, in town service, with inside control, a wide entrance, magnificent upholstery, and driven by ladies

PIONEERS in the vineyard of electric vehicles, the Woods Motor Vehicle Company, with its large plant at Chicago, offers refinements in its 1910 cars that are in keeping with the stand this company has always taken, even when electrics were at a low eb, which, to be sure, was some years ago. The refinements, while they are positive, fall far short of revolution, being confined to such matters as will add to the radius of action of the cars and to the life of the battery. Luxuriousness, insofar as this phase of the business is concerned, reached its apex last year, and in the Woods plant, at any rate, little could be added from the style point of view, for 1910 Fig. 1 depicts a Woods, a coupe, making its daily round in one of the classes of service to which electrics are dedicated by fitness and good taste, roominess, as well as stability, are all sufficiently pictured to depreciate any further effort along this line.

Self-Contained Power Plant Presents Flexibility—It has long been known that one motor is far more efficient than two, and efficiency is the matter of greatest moment in the motor equipment of an electric vehicle, in view of the battery, which must have a wide radius of action and a long life as well, if cost of service, as well as extent thereof, is to be up to a fitting standard. To conserve the battery is to limit its output, and in order to realize a wide radius of action, it is necessary to build up the torque of the motor in keeping with the expenditure of energy, which is a matter of using a unit power plant, and it, too, must have the desired characteristics.

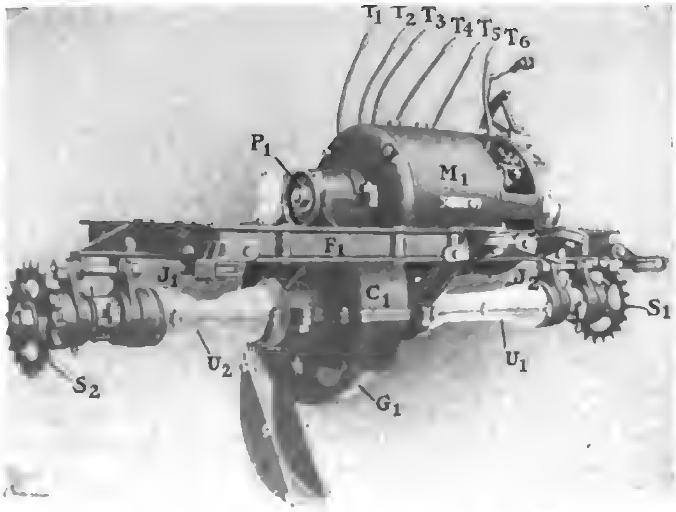


Fig. 2—Self-contained power plant, mounted on a manganese bronze frame, with tumble-shafts, universal joints, and great flexibility

It is not the maximum efficiency of the power plant that counts: the mean efficiency must be noted, and this mean efficiency will be on the highest level if the motor is so designed that the torque (twisting moment) will be in direct proportion to the current in amperes which must be taken from the battery. The torque, for current, of the motor depicted in Fig. 2 has been determined in the Woods laboratory, and it may be set down as follows:

TORQUE IN RESPONSE TO CURRENT EXPENDED

Current in Amperes	Torque in Pounds—Feet
10	2.4
20	8.8
30	16.6
40	25

From the above it will be observed that he torque of the motor is almost in direct proportion to the battery output, and the draft on the battery is limited to that which is safe. In the meantime, the speed of the motor decreases as the torque increases, about as follows:

DECREASING SPEED WITH INCREASING TORQUE

Speed in Revolutions per Minute.	Current in Amperes.	Torque in Pounds—Feet.
1,820	10	2.4
1,600	11.6	2.9
1,400	13.3	4.0
1,200	16.2	5.9
1,000	20.0	8.8
800	28.2	15.0

The above values are as nearly as possible taken from curves plotted for the purpose, with data from actual tests, in a well equipped laboratory, the actual curves to be presented in an article to be prepared on the subject of the laboratory.

From what has been shown, it is possible to predict that the efficiency of the motor is nearly constant for the entire range of performance, and that the maximum efficiency will be at the highest speed and lowest current stated. The fixed losses are very low. This is the reason why the maximum efficiency is at maximum speed, it being the case that the I^2R losses increase with the current, they being in proportion to the square of the current, and by using copper wire of relatively large section the internal resistance of the windings on both the armature and fields is held so low that increased torque is not attended by heavy losses, and the efficiency of the motor at all speeds is maintained nearly constant, as the following tabulation will indicate:

EFFICIENCY IN RELATION TO CURRENT IN AMPERES.

Efficiency in Per Cent.	Current in Amperes
82	10
84	20
81.6	30
75.9	40

When it is considered that these values for efficiency interpret all losses, it will be recognized that electrics have reached a high state, and there are good grounds for claiming that battery life is now satisfactory. Referring again to Fig. 2, M1 is the motor, transmitting power to the gear G1, through the pinion P1, which is equalized by means of a differential gearset within the case C1, and in proportion to the needs the power is transmitted through the universal shafts within the cases U1 and U2, to the sprockets S1 and S2. The frame F1 fastens to the underbody, which acts as a chassis frame, and by means of hinge joints J1 and J2 the motion of the body is compensated for so that the sprocket chains are maintained in perfect alignment.

Electrical connections are made by means of terminals T1, T2, T3, T4, T5 and T6, which lead to the windings of the motor, and by means of the wiring system provided in the body proper connect with the controller, through which to the battery, thus completing the connections for the desired purpose. This electrical wiring system is more completely presented in Fig. 3, which offers evidence of the very systematic way in which the wiring is cared for, it being the case that every part of the wiring is accessible for repair, and what is more to the point, it may be inspected at will. These provisions do not prevent adequate protection of the wiring at every point, so that depreciation, which was in former times a serious matter, is reduced to the vanishing point in these cars, due to the continual effort, which followed in the years of practice.

Design Features of Motor Portrayed—Fig. 2, while it shows the motor in combination with the means for its proper application to the work, is too complicated to properly bring out the design features that make for entire success, so that Fig 4 is here offered for the purpose of accentuating the remaining points to be touched upon. In this figure A1 is the armature, which is laminated and slotted to accommodate the windings W2, of which there are a suitable number, and the alternating waves are commuted at the commutator C1, which is made of a considerable number of "lake copper" segments, each insulated from the other and the frame by means of laminæ of Indian amber mica of the finest selection. The laminæ of the armature are of Swedish iron, rendered soft by annealing and aged to prevent hysteresis deterioration. The armature windings W2 are what are technically designated as "form wound," insulated with "sea island" cotton and taped. They are then saturated with insulating varnish and baked to expel dampness, which process seals up all the little openings and dampness cannot thereafter penetrate into the insulation.

As an additional precaution against that dread foe, dampness, the terminals are all shellacked several times.

The armature revolves on the shaft S1, in Hess-Bright ball-bearings B1 and B2, which shaft is of special steel, ground to exact size after machining, and the whole is balanced both in a kinetic, as well as a static sense, on a suitable balancing equipment after the work is done. The Hess-Bright ball-bearings, B1 and B2, fit in the bore of the housing spiders S2 and S3, which, in turn, bolt to the circular field magnet F1, in which the four poles, one of which is designated as P1, are secured, on which poles the field windings, one of which is designated as W1, are placed, after they are form wound. Current is led to the commutator C1 at four diametrically opposite points by means of brushes, which are clamped into four holders, one of which is indexed B3, they being secured to, but insulated from, the housing spider S2.

The armature windings, which are done in a winding machine, are shaped as in Fig. 5, in which A is the plan, B is looking at one diameter, and C is an end view. The number of

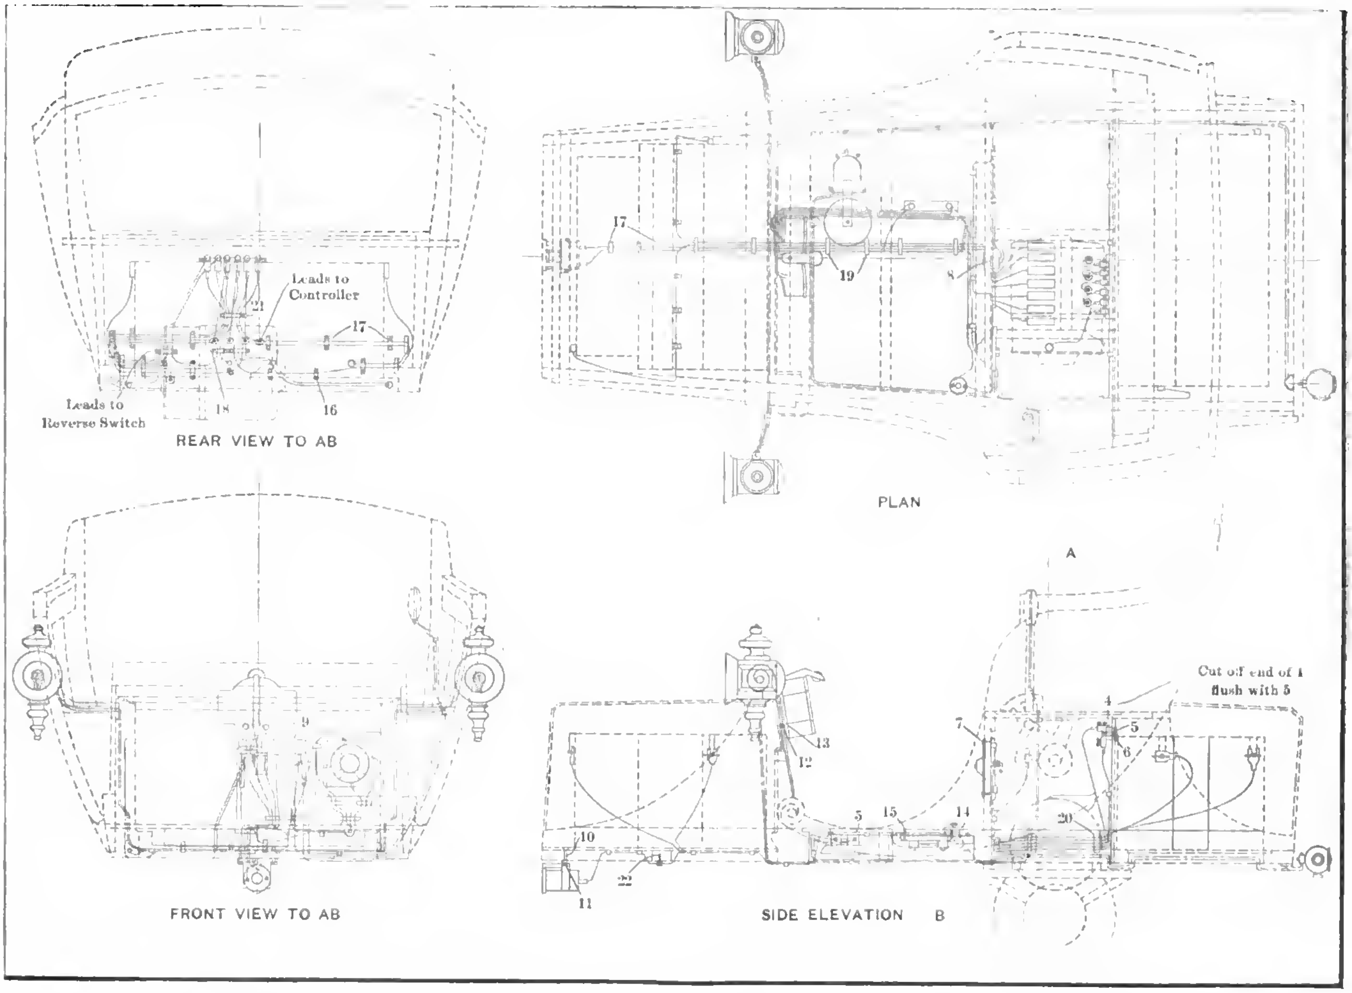

Fig. 3—Skeleton of body, showing how wiring is done, location of controller, and two halves of battery

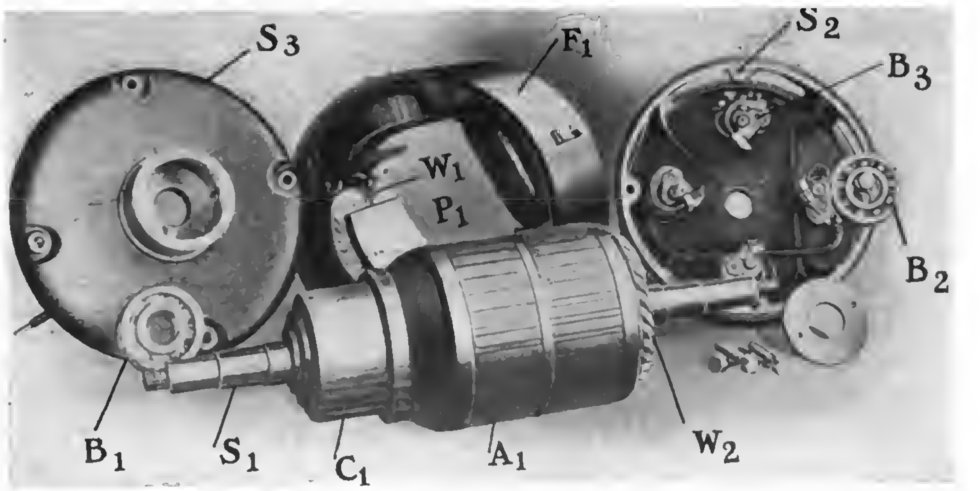

Fig. 4—Component parts of motor, presenting slotted armature, ball-bearing spindle, and form-wound laminated fields, all enclosed

turns, number of complete coils and process of insulating is stated in the figure. The armature slots are presented in Fig. 6, at A-B, on the periphery of L1, there being 33 of such slots. The transformer iron of which the discs are made is shown as respects thickness by L3, the plan of which is offered at L2. The discs are keyed onto the shaft, keyways K1, in L1, and K2, in L2 checking with K3 in P1, and K4 in P2. P1 and P2 are the end plate by means of which the discs are clamped into tight relation on the shaft or armature spindle, as it is called. The respective plates L3 are 0.017 inch thick, and to permanently insulate them, japan is put on evenly by means of a printer's roller, and they are baked in an oven. This is an extremely important process, for if paper is used instead, as it sometimes is, the heat, which is quite high when overloads are encountered, will char the paper and the insulation will then be destroyed.

Laminated Fields Are Form Wound—Referring to Fig. 7, P1 is the plan of the winding, of which four are used, and the terminals T1 and T2 are of heavily insulated flexible wire, leading out to the terminals. There are 63 turns of wire on each coil, and the whole coil is taped in the manner as indicated. P2 is an edge view of the coil and P3 shows the same coil in end view. The details involved in establishing perfect conditions of insulation are stated in the figure. The polar extensions (pole-pieces), as shown in Fig. 8, are of transformer steel, excepting the heavier end plates, which are placed as retainers and to give a backing for the rivets. These plates are 0.031 inch thick, coated with japan and baked, and with the polar horns, shaped as they are, with tangent terminations of the radius 3.0825, the computation is absolutely sparkless, which is a matter of the greatest importance, and fixed losses are confined to a minimum.

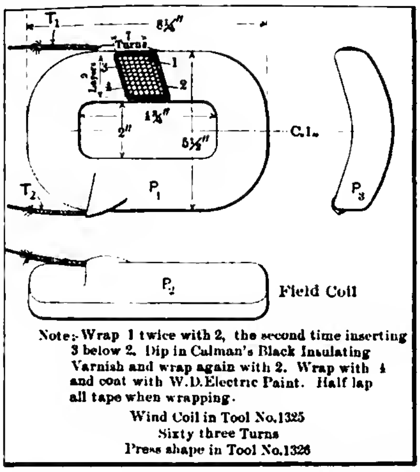

Fig. 7—Form-wound field coils, showing number of turns of wire per coil, shape of winding and method of taping to exclude dampness

Noise, due to friction of the brushes as they press on the bars of the commutator, is scarcely to be noticed at all, due to the very careful manner in which the details of this part of the construction is executed, which, unaccompanied by good design, would scarcely suffice for the purpose. Friction losses, for the same reason, are minimized, and as friction is reduced, wear is eliminated to a vast extent.

How Flexibility Is Retained Without Handicap—In order to clearly depict the power plant with a view to offering the best evidence of flexibility, it will be best to present a section through the motor, universal joints, tumble shafts, etc., as offered in Fig. 9, in which M1 is the motor shell, B1 and B2 are Hess-Bright bearings on the armature spindle, P1 and P2 are the two halves of the herringbone pinion, which meshes with G1 and G2, which are the two members of the herringbone gear, which, in turn, is flanged onto the differential gear housing H1 and is held in place by holding bolts, B3, B4, etc.

The differential system is of the bevel type, with members G3 and G4 keyed to short shafts S2 and S3, and compensation is established by means of planetary pinions P3, P4, etc., which mesh with the gears G3 and G4, which pinions rotate on spindles of the spider S, which in turn rotates on the bearing B5, being threaded over the ends of the shafts S2 and S3, serving to fetch up the gears G3 and G4 on the tapers T1 and T2, keys K1 and K2 also being provided to resist all twisting moments. Hess-Bright ball-bearings B6 and B7 support the differential housing H1, and the power of the motor is duly transmitted to the tumble shafts S4 and S5, through the universal joints J1 and J2. From the tumble shafts S4 and S5 power is transmitted to the sprocket pinion shafts S6 and S7, through the universal joints J3 and J4, from whence the power passes to the sprocket pinions P5 and P6. The stub shaft S6 and S7, on which the sprocket pinions P5 and P6 are keyed by means of keys K3 and K4, runs on Hess-Bright ball-bearings B6, B7, B8 and B9.

The sprocket pinions, on their stub shafts, being in housings H2 and H3, which in turn swing free on hinge joints J5 and J6, connect with the supporting frame F1 in such a way that the distance rods D1 and D2 maintain the center to center distance between the sprocket pinions P5 and P6 with the respective sprocket wheels on the rear road wheels of the car. The distance rods have no more to do than to sustain against the torque of the motor as it is taken by the sprocket chains, and as to the chains, they run noiselessly because the spacing can be accurately maintained. True, in order to assure noiseless sprocket work, the sprockets are cut accurately, using good material in the sprockets, and the most approved machine tools for the fashioning of the teeth, taking into account the desired clearance and absolutely accurate bottom distance of the teeth.

Mud is excluded by means of the shells S8 and S9, which have ball joints J7, J8, J9 and J10 over the universal joints. These shells co-operate with the housing H4, which, in turn, passes up and sleeves over the shell of the motor at M2 For the rest, as the figure depicts, a brakedrum D3 is keyed K5 on the end of the armature spindle and a nut N1 threads onto the end of the spindle, pressing the drum D3 up to a proper fit. The brakeband B10 is faced with friction material F2 and the band is prevented from rotating when pressure is applied by means of the pin P7, which is secured in a reamed hole in the boss B11 of the spider S10. Pressure is applied to the brakeband by means of the lever L1, when a pull is applied to the cable C1 in the groove C6. Electrical energy is supplied to the motor from the battery through the controller by means of the cables C2, C3, C4, C5, C6 and C7.

Noiselessness Attained by Attending to Details—Glancing at Fig. 10, which is of the gear system, it will be plain that designing for noiselessness was the great question, and it comes as an incident that this same desire is only to be carried to a successful termination by the use of superior materials and the closest possible limits of tolerance in the shop. The herringbone idea is reduced to practice in this example by accurately machining two members for the gear and pinion respectively, and they in turn are cut spirally, so that when they are bolted together they eliminate "backlash" and transmit the power of the motor noiselessly.

A Hundred Details Bespeak Quality—Were it possible to present every working drawing of the cars made it would then be a simple matter to point out to what extent details in design are perfected. Rather than space every drawing, which would render this story futile, in a mass of detail, just one or two characteristic examples will be taken instead. Fig. 11, for illustration, shows how cables are secured to brakearms, and since the cables are of silico-bronze, which is permanent and strong, the equalization of the load between the two brakedrums is taken care of by means of pulley blocks. The method here shown offers strength, ease of repair, and eliminates uncertainty.

Fig. 12, of the steering control system, is sufficiently clear as not to require discussion in detail. The tubing used is cold drawn nickel steel, and the ball and socket joints are made from die forgings of special steel, machined accurately, heat treated to render the bearings glass-hard and the whole high in shock ability. Referring to the ball joint on the end of the steering arm L1, the safety member S1 prevents the ball from departing from the socket, and dirt is excluded as well.

Among the other details not shown the drum controller may be mentioned as entitled to space alone, it being of the street railway type, strong, well made, properly insulated, and lasting. This controller is selective in action, and affords absolutely no chance for the operator to make a mistake. The Woods platform springs make for easy riding, and the solid tires, made from a rubber composition by Woods' formula, work so well that road inequalities are readily negotiated The use of Hess-Bright ball-bearings of the well-known annular type in road wheels as well as throughout the power plant is calculated by the Woods designer to eliminate nearly all friction, and tire tests, using the Woods tire dynamometer, have demonstrated many points which were taken advantage of from the tire point of view, showing that there is much to be gained by selecting tires of proper sizes, and suitable material.

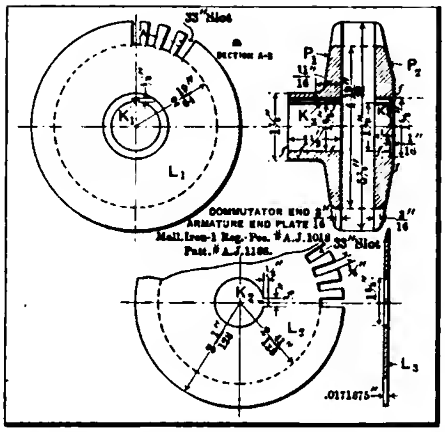

Fig. 6—Armature laminæ, showing plan of slotting, thicknesses of laminæ, method of securing, and details

ELECTRIC VEHICLE INCREASED OVER SIXTY PER CENT.

By LOUIS E. BURR, President Woods Motor Vehicle Co.

ELECTRIC vehicles to-day are an assured success, and their popularity in the larger cities is increasing very rapidly. Vehicles propelled by electric power cannot be compared at present to the gas car from a selling standpoint on account of the very significant fact that in smaller cities there are few garages that have taken the trouble to post themselves on the proper care and maintenance of the electric car. This feature in the care and maintenance is of the very greatest importance in connection with the electric vehicle. Almost any garage is equipped to take care of a gas car more or less successfully, but comparatively few are yet able to give the electric vehicle the attention and care it requires, and for this reason alone the electric car has not made the progress it should in point of sales in the smaller cities. The rather extensive campaign of education that is now being carried on by the storage battery companies and the electric vehicle manufacturers is eliminating very rapidly this feature in connection with the sale of electrics, and it is a question of a comparatively short time only when the smaller towns will recognize the very great convenience of the electric car and its cheapness of operation, and adopt its use just as vigorously as it is being adopted in the larger cities in proportion, of course, to their population.

The several cities in America, where the better class of electrics are manufactured, have larger numbers of garages well equipped to give the electric car the proper care, and for that reason electrics are very popular, as evidenced by the great num-

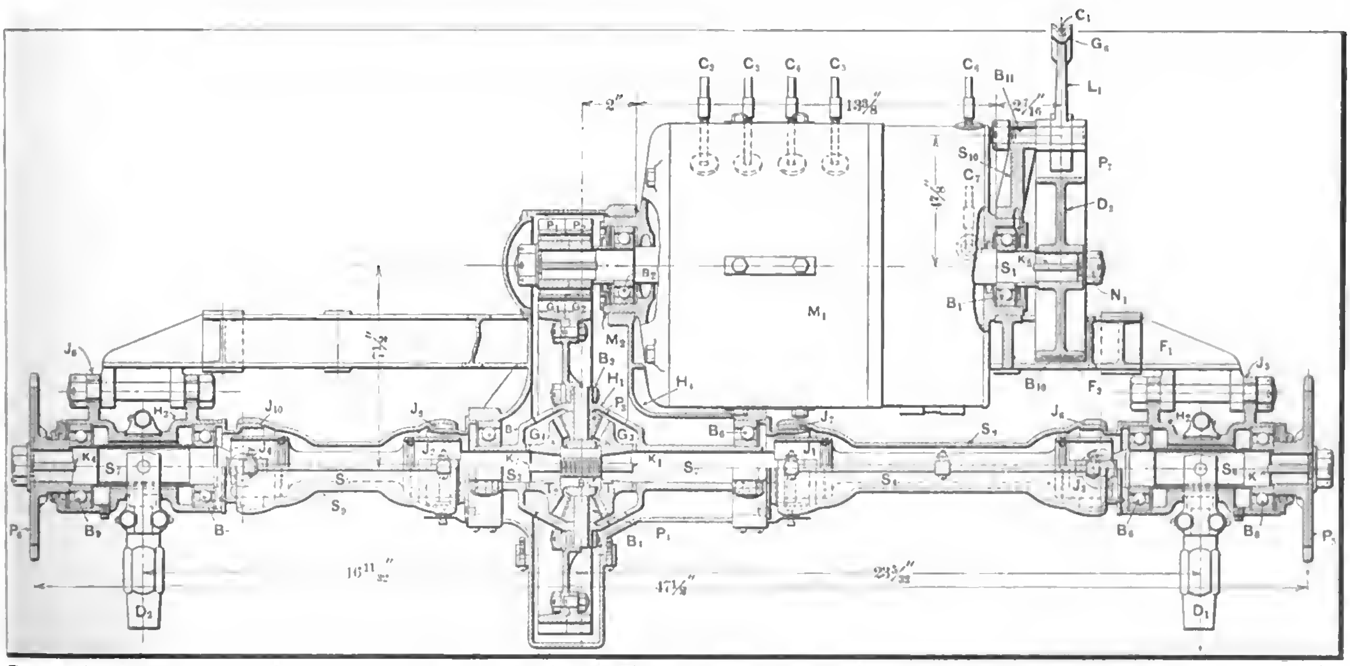

Fig. 9—Cross-section of power plant, from working drawing, showing exact relations of components, precision of fit, and how the differential gear is connected to the system

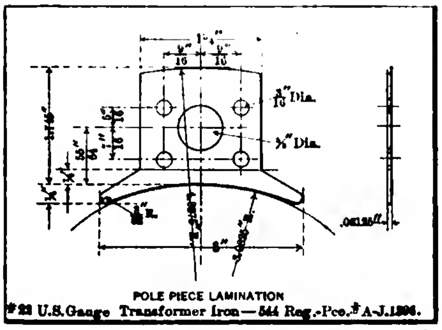

Fig. 8—Laminated pole piece, shape of horns, and method of riveting

bers that may be seen in daily use on the streets of these cities. This fact is easily explained, of course, because the manufacturers of the electric vehicles have taken pains to educate the garages in their own cities, and furthermore have established a more or less regular inspection system which checks up the garages and compels them to give the cars in their keeping at least the ordinary care they should have.

Many people believe that the electric machine is very limited in its use, and suitable only for cities with very level streets. As a matter of fact this is entirely a wrong impression, as very hilly cities like Seattle, Duluth, Kansas City, Pittsburg and Philadelphia have a large number of electric machines in daily use that give perfect satisfaction, and it is only a question of a short time when these cities above mentioned will have their full quota of electrics the same as they have in the gas car line.

To sum the matter up from a selling standpoint, which is the particular feature in this article, the electric car awaits only the education of the people all over the country. This campaign of education is being carried on by those interested in the sale of the electric machine, and it is a question of a short time only when good garages, in all cities, fully equipped to take care of the electric car will be established and the public will become aware of the many advantages accruing from the use of an electric car, not only in point of convenience, but also in the matter of cheapness of upkeep and operation.

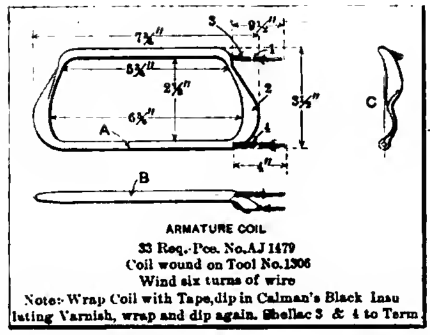

Fig. 5—Plan of armature windings, which are wound in a machine, taped, then submerged in insulating compound, and baked

The electric vehicle should never be compared to a gas car because it fills an entirely different position than that occupied by the gas car, and it is only claimed by the manufacturers of electrical vehicles that its use is suited to those who require a vehicle for moderate distances and moderate speed, and almost entirely for personal use and operation.

Statistics show that the electric vehicle industry has increased over sixty per cent. during the past twelve monhs, and from very good sources information has been received indicating at least as great a percentage increase in the coming twelve months. Is is also well appreciated that electric work is now on a plane as never before; the problems are better understood, and much more care is exercised in every detail of the undertakings. Methods of manufacture are thoroughly well grounded; the most approved processes are used and the engineers, who must be relied upon for results, are in better fettle than ever before, while companiees are more inclined to listen.

THE IMMEDIATE FUTURE OF THE ELECTRIC VEHICLE

By FRED J. NEWMAN

ONE of the greatest uncertaintics on any car, as far as operation without breakdown is concerned, is the pneumatic tire. It makes a great deal of difference as to the power consumption in regard to what kind of a tire is used. In order to make cars light or to have extreme mileage capacity many manufacturers have adopted a special electric type of pneumatic tire, being a development of the single tube Palmer tire of the bicycle days. The construction of this tire is such as to make it very weak, and it is safe to say for a tire that the less power consumption the less life it has. A solid tire rubber composition has been developed which causes the tire to consume less power than the regular composition found in tires on the market. It has been found that either through lack of knowledge in the power consuming qualities of tires or on account of the silvery tongue of a tire salesman regular gas car tires are put on the car with the result that the car runs slower, consumes more power, gives less mileage, and also electrical parts become overloaded. Inasmuch as the solid tire has a very much greater life it is safe to presume that the car will run a much longer time before tires need renewing. As a result the car will run several years before it gets into the above-mentioned difficulties. On the other hand, inasmuch as the solid tire has lasted a long time no good sales argument can be offered to replace these worn tires by those of a different make. Considering reliability: A car will have solid tires.

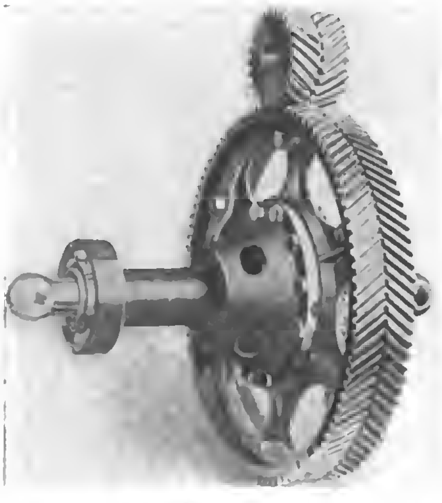

Fig. 10—Herringbone toothed pinion and gear, with the latter flanged to differential gear housing

Solid Tires Demand the Use of Good Springs—To use solid tires it is necessary to have a good spring construction and to make everything below the vehicle springs of as light weight as possible. A good spring construction is not necessarily confined to the spring alone, but to the general "hanging" design. Good springs must have a large deflection with a slow period of vibration and ample margin of safety in regard to fiber strain after the springs have reached their full deflection. Springs of ample deflection cannot be so staisfactorily obtained in the half elliptic construction as in the full elliptic and platform type. Then, again, to get a good deflection without straining the material too much means long, thin plates of good material, properly heat treated and plenty of them. A slow period of vibration necessitates long springs, and to obtain slow periods throughout means a long wheelbase with a well balanced car between.

The limiting dimension for wheelbase is governed by the width of street, gauge of car and front width of chassis frame, consequently the following specifications are developed:

(A) Wheelbase in the neighborhood of 85 inches.

(B) Full elliptic or platform springs made of alloy steel.

The lightest rear axle and a system in which the maximum amount of weight of the gearing and propelling parts is above the springs is obtained by side chain drive. Stiffness is obtained by an I-beam section and life of axles by the use of high grade, properly heat treated materials. To which I am inclined to add the following specifications:

(C) Side chain drive; and

(D) I-beam axles in one piece, of alloy steel, heat treated.

In order to keep the power consumption as low as possible, it is necessary to maintain the axles absolutely parallel and at right angles to the direction of running. When the body surges from side to side, if regular gas car side chain drive construction is used, the rear axle moves out of parallelism; also in case chains are not equally adjusted as to center distances. It is necessary to add a specification to overcome this objectionable feature.

Electrics Are Intended for Winter's Service—Electric cars must of course, run in the Winter as well as Summer. To gain distance over snowbound streets the running in car tracks can be resorted to, so let us add:

(E) Width of gauge; gauge of standard street car track.

Motors for electric cars cannot be satisfactorily rated in horsepower, since no specific standard can be agreed upon. If the motors were rated for a continuous all-day run the publicity departments of the electric companies would be surprised at their low power and, of course, some objection would be had from this source. The discharge of the battery becomes a good safety valve, for outside of good commutation and torque characteristics the capacity of an electric should be stated in terms of time and temperature. For this reason let us write the motor specification as follows:

(F) Motor of such capacity that battery is discharged before motor is dangerously hot.

A maximum speed of slightly less than twenty miles per hour is what this car should have, with three or four speeds below this of uniform graduations. The car should be able to run fifty miles on a charge in hilly cities every day in the year, and to do this it means the battery capacity must be such as to never have to be discharged below a point where there is over 10 per cent. loss in speed from beginning to end of the discharging run.

At least two sets of good and powerful brakes are needed. The construction must be such that much oiling is not necessary, and if it is necessary to oil, place grease cups so prominently that oiling becomes self-evident. This is stated because (especially in public garages) no oiling takes place until it is necessary to use means for removing rust.

The same may be said of the steering gear. In this connection let us add to the specification side lever steering on the left side. Side lever for its simplicity, its quickness of operation, and because the speed and road conditions do not necessitate any other form. Left side because in stopping the car on the right side of a street (the correct side) it is easier to get out of the car.

Ball or Roller Bearings Must Be Used—Anti-friction bearings, the best that money can buy, should be a part of the equipment. They serve the following—reduce the power consumption, eliminate oiling, and produce reliability. The bearings must be properly housed, in order to insure long life. It is necessary to keep out dust and water and retain a large amount of oil and grease.

All working parts should be as accessible as possible, and those parts which require inspection the oftenest should be the easiest of all to get at and the most simple to cope with.

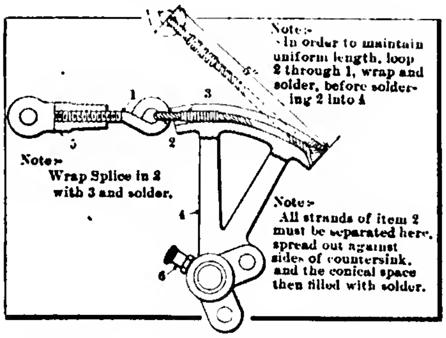

Fig. 11—Quadrant lever to which brake cable is fastened, offered to indicate extent to which details are worked out

About the battery a good deal can be said—what the ultimate construction and type will be is probably as hard to predict as when flying machines will run on schedule time across the Atlantic.

The lead battery of to-day is a commercial success. It will not be necessary to have a battery of imaginative newspaper descriptions to increase the electric in numbers in their chosen field. A battery slightly lighter for a given capacity is not necessary—if it is desirable to have it lighter no great change in design will take place unless the battery is reduced in weight by 75 per cent.

The matter of life now puts the electric vehicle in a high rank at present day transportation economies on account of convenience. There is a great opportunity for economies here, just as there is in any proposition, where operating cost is considered. Taking then only the battery equipment with the possible immediae improvement, we can develop the specifications as follows:

High voltage—within the range of easy insulation problems—is preferable from the standpoint of economy of transmission than low voltage. The transmission loss for a given current transmitted is represented in volts and is independent of the transmitting or impressed voltage. It is therefore evident that as the impressed voltage increases the percentage of volts lost decreases. The limiting maximum voltage is that which is regulated by the maximum voltage obtained in the majority of places. The direct current is necessary for charging and as the 110-volt supply is the most prevalent, 40 cells should be the equipment, for this is the largest number of cells which can be satisfactorily charged from such supply. If a less number of cells be used the difference in voltage must be lost in resistance so that the charging is uneconomical. Then again, if two designs necessitate the same watt capacity, the one with the lesser number of cells is at a further disadvantage, for besides the voltage loss taken care of in the resistance additional current is required on account of the distribution of the plates and the charging becomes uneconomical.

It has been suggested to charge several cars together if the voltage is 100 per cent. too much for one car, but this at the best is only a makeshift scheme and is unsatisfactory. This may not be altogether true in the case of where the supply is alternating current, but it holds true, only to a lesser degree. It is impossible to anticipate the charging supply for any given machine, so it is necessary to provide against the greatest abuses of economies.

Battery Should Be Stable Rather Than of High Capacity—Battery capacity should not be obtained by a multiplicity of thin plates because thin plates mean short life. Thick plates represent the greatest economies because in manufacturing there are certain fixed factors in costs, and as a consequence thin plates cost more for a given weight than thick ones. Obtain vehicle mileage capacity by means of substantial battery plates and make the equipment of such a nature that it can satisfactorily carry a battery of 40 cells and enough substantial plates to give the necessary results.

Body design is a matter of development. The trend now seems to be entirely to an inside operated machine, with decided effort in the direction of greater stability.

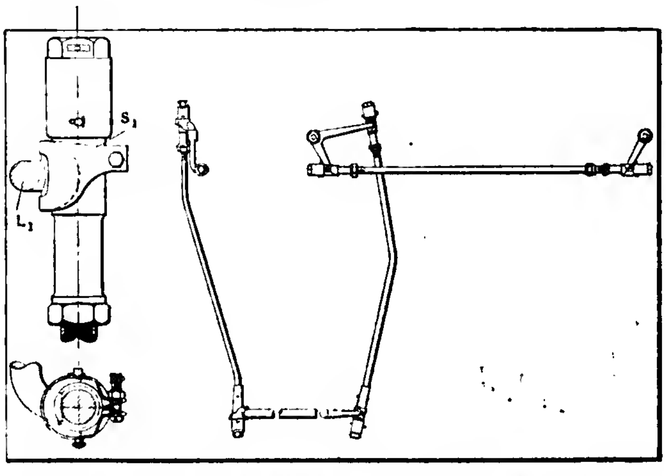

Fig. 12—Diagrammatic arrangement of control system in steering, showing arrangement of parts, nice details, and suitable design

GLIMPSE OF 1911 IN ANHUT CAR

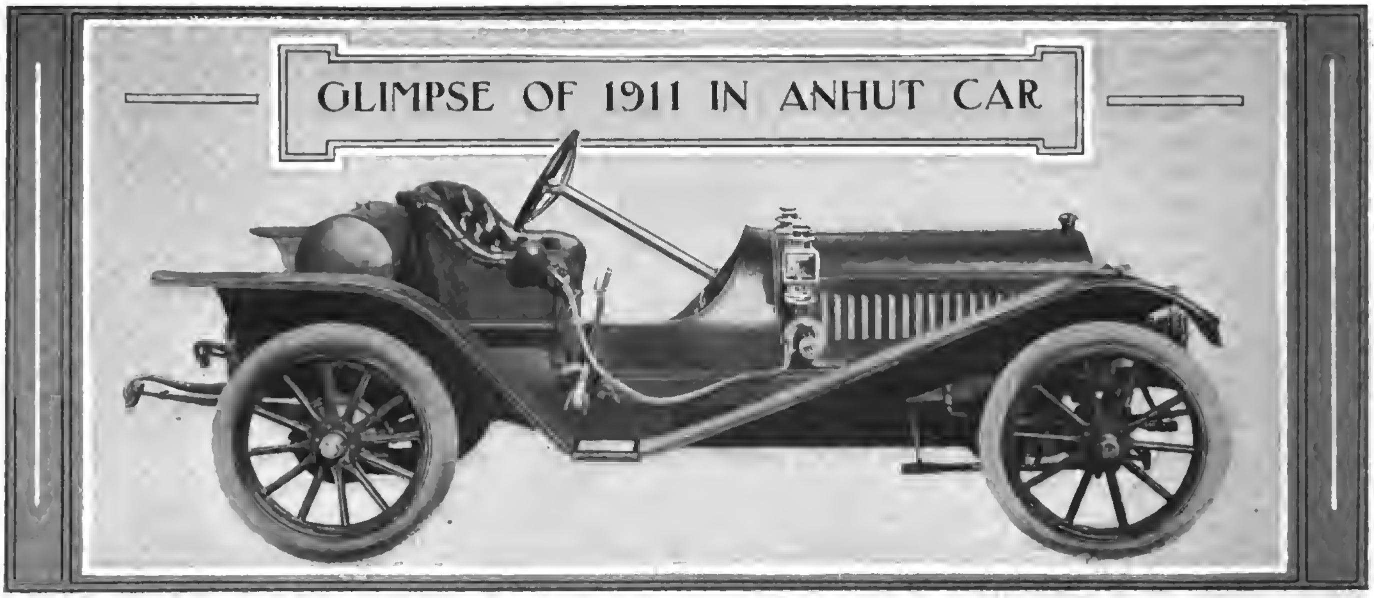

Fig. 1—Roadster, with a round gasoline tank back of seat, flaring mud-guards, 17-inch steering wheel and 110-inch wheelbase.

LOOKING backward, while it has the virtue of enabling one to note progress, affords no such pleasant occupation as "peering into the future." The Anhut maker, Anhut Motor Car Company, located at Detroit, Mich., offers, in Anhut cars, such evidences of standardization as to enable the company to claim that the car of the future is represented in the very automobile that the company is now placing at the disposal of buyers.

This car is a "six," using Brownell motor equipment, and like the motor, all the other units are standardized by time and success. In is the Anhut idea, according to the information at hand, to accept, as standard, the very designs that have faithfully performed from the start, claiming that, while the designer might like to interject his individuality, it is not wise to experiment in the face of certainty. This is not to be construed as evincing a desire, on the part of Anhut designers, to falter in the advance, but there are some things that show principle, deliver satisfaction and, in a word, of all the jewels in a crown, there is the brightest one. Sorting out the jewels requires that the eye of the expert must be utilized for what it is worth, and the principles of design that have earned the title of "standard," according to Anhut representation, will be found in Anhut cars for 1910, and force of deduction, if the first contention is true, makes it possible to proclaim that, in the Anhut, is a glimpse of 1911.

General Scheme of the Anhut Design—Briefly, the power plant, which, after all, is the most important part, is of the unit type, with the motor, clutch, and transmission gear in a single housing, and the whole is suspended on three points. The motor is of the four-cycle, water-cooled genera, with six cylinders. The power is transmitted by means of a propeller shaft, with universal joints, to a live rear axle of standard characteristics, and the wheels, on which the car rolls, are of artillery pattern, with second growth hickory spokes and felloes, of a size to take 34 x 3½-inch pneumatic tires. Semi-elliptic springs, front and rear, with thin, wide plates in sufficient presence. assure easy riding, and the channel section chassis frame is the platform on which the equipment rests. The brakes, in order that they will compare favorably with the rest of the plan, are of assured ability, they being of the external constricting and internal expanding type, engaging drums which are flanged to the rear road wheels. For the steering gear, enough is to say it is of the worm and sector type, and a 17-inch hard rubber rim steering wheel is at the disposal of the driver. For the rest, considering the car as a whole, the wheelbase, which is 110 inches, with standard tread, makes for good road work and lightness as reflected in I-section front axles, and in many other ways, is not at the expense of strength; but this same lightness, considering a 36-horsepower motor, does represent road work, under all conditions, that should be adequate for the needs of the most exacting motorist. In order, however, that the car will be more clearly portrayed, it will be necessary to illustrate the units, and to some extent, at any rate, reproduce actual working drawings, from which the car is built.

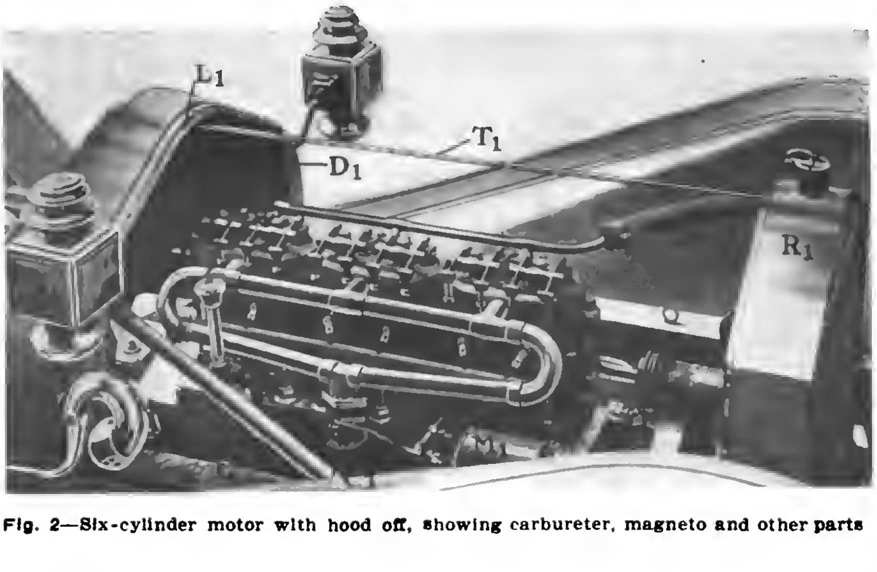

Fig. 2—Six-cylinder motor with hood off, showing carbureter, magneto and other parts

General Appearance of the Car—While the Anhut is made in two general types, the one a pony tonneau and the other a roadster, it will be, for the purpose here, enough to show the roadster. and the title illustration, Fig. 1, discloses much for favorable art criticism. The radiator, for illustration, rests over the front axle; the hood is long enough to accentuate the scheme of the designer, which is to include every evidence of a strictly roadster type of car, and the driver's seat, which is located nearer to the rear than the front axle, is in just the right place to assure the most easy riding qualities.

The seat is low, close to the deck, and the steering wheel is located in the position which was found in racing experience to be the most comfortable and of the greatest utility. The gasoline tank, which is just back of the seat, is round (shape of greatest strength) and is of sufficient capacity (20 gallons) to assure an adequate radius of travel. The springs, especially at the rear, are with but slight bow, and the rear extension of the chassis frame, which engages the spring shackles, is shapely and slender, thus possessing the utility of being limber, and of the appearance desired. Of the mud-guards, it may be stated, they are wide, of flaring set, and rigidly supported; the step, which is just in front of the front line of the seat, is stoutly ironed, and in all the little details which make so much for appearance and satisfaction the fine Italian hand of the designer is indicated by the imprint of its fingers.

What a Peep Under the Hood Discloses—In lifting the hood it will be observed that the character of the work is up to a fitting standard, and, as shown in Fig. 2, a tierod T1 holds the radiator R1 in rigid relation. The tierod being fastened to the dash D1 and a ledge L1 is beaten into form, out of the material of the dash overhang, to serve as a resting place for the hood. The filler F1, for the radiator, is hinged, and a locking bale passes over a cam-shaped rib, by means of which the cover is rendered tight, but it can be swung back at small effort when it is desired to fill the radiator, which, including the cooling system, holds four gallons of water.

Peering in at the motor and its accessories, the carbureter C1 is high enough up to be accessible, and the valve-actuating mechanism is up and above-board, where it can be inspected and worked upon. Likewise, the magneto M1 is above the level of the top of the chassis frame, which is a matter of more than a little moment in these days when accessibility is regarded as of the first importance.

What the Motor and Transmission Look Like—While looking under the hood has the virtue of affording information of a definite character on the subject of accessibility, the fact remains that in order to appreciate the points of merit residing in the power plant proper it is necessary to withdraw it from its surroundings, which is done in Fig. 3. The crankcase C1 is of aluminum, flanged F1 between the motor-case and the gear-case, and split horizontally in the crankshaft axis. The flywheel F2 is in front, and the fan F3 is driven by a round belt B1, while the fan is suspended from a round section bracket B2 and rolls on ball bearings in the fan-housing H1.

The six cylinders of the motor, C3, C4, C5, C6, C7 and C8, are cast in pairs, and in Fig. 3, which is the right side of the motor, the carbureter (a Stromberg) is connected to the intake ports by means of a manifold M1, which balances the pressure by circling around through its two branches, connecting to the three ports of the three pairs of cylinders at P1, P2 and P3 (the latter not shown). The magneto is on the right-hand side also, rests on a ledge cast integral with the uper half of the case, and is driven by a gear of the encased train, as a part of the half-time system which fixes the speed of the camshaft.

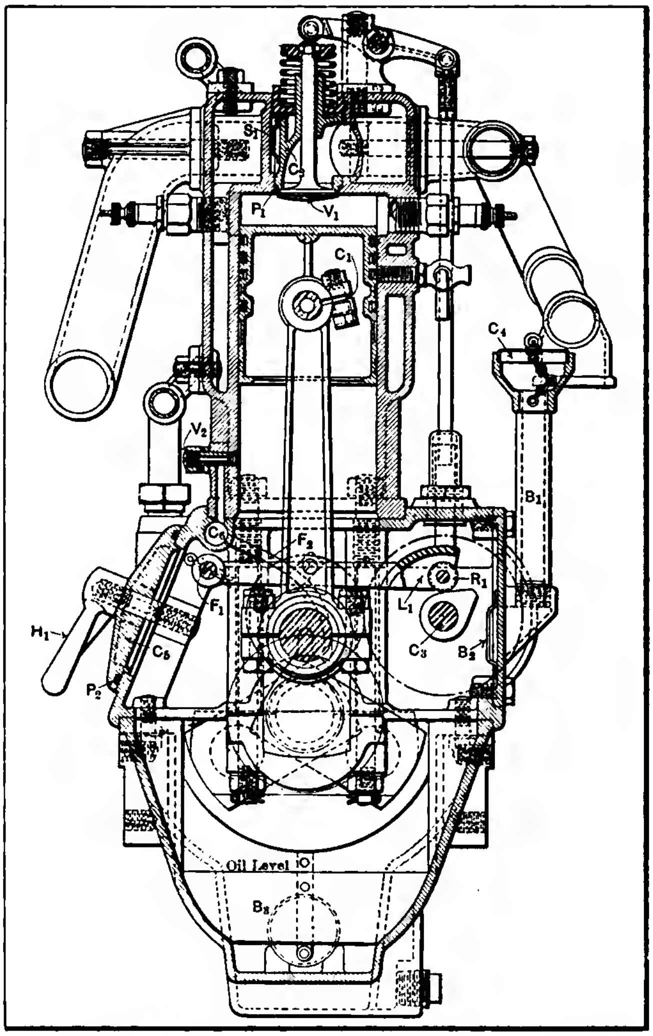

Fig. 4—Cross-section of motor, showing position of camshaft

The camshaft, which is inside, is on the right side of the motor, and the tappet rods extend up from the lifts L1, L2, L3,

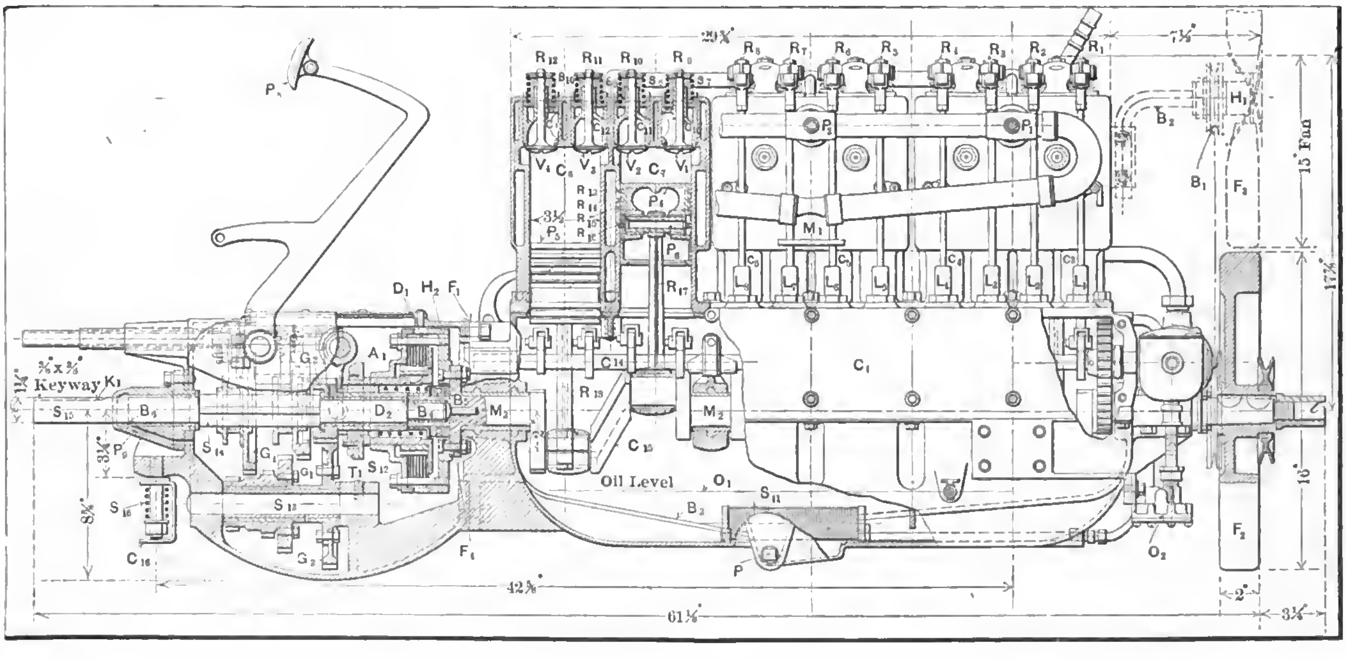

Fig. 3—Sectioned elevation of the six-cylinder Brownell motor, offering evidences of refinement and special means of lubrication

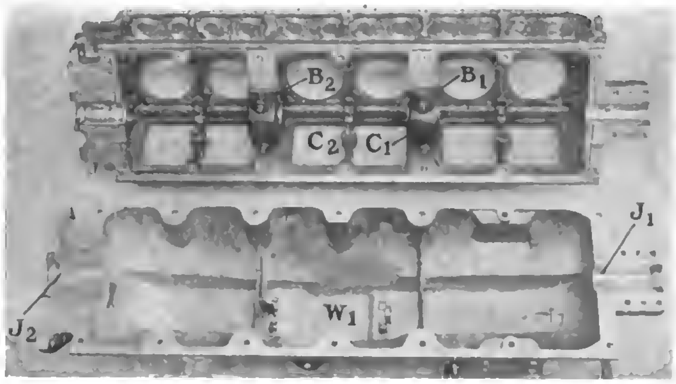

Fig. 5—Top and bottom halves of crankcase, showing caps over journals, formation of bottom half for oil-basin, and strength

L4, L5, L6, L7, L8, L9, L10, L11 and L12 (the last four not shown) to the rocker arms on the top of the cylinders R1, R2, R3, R4, R5, R6, R7, R8, R9, R10, R11 and R12, R9, R10, R11 and R12 being cut away to show the section of the cylinders, presenting a view of the valve springs S7, S8, S9 and S10, the valve cages C10, C11, C12 and C13, and the valves in the heads V1, V2, V3 and V4, as shown in the section of the last two cylinders, it being

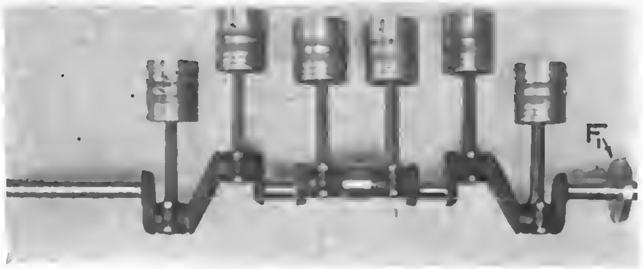

Fig. 6—Crankshaft assembly, depicting flange at rear, flywheel bearing in front, and lightness of reciprocating parts

the case, of course, that two valves (inlet and exhaust) are placed in the head of each cylinder.

The bore of cylinders is given as 3 1-2 inches and the throw of the crankpin is given as 2 inches, thus making the stroke 4 inches. The pistons P4 and P5 are like the cylinders, of cast gray iron, and light. Each piston is provided with three rings R13, R14 and R15, above the crosshead pin, to render the pistons tight against compression, and one ring R16, which passes through a slot in the crosshead pin P6, to keep the pin from floating out. The camshaft C14 is shown at the sectioned end of Fig. 3.

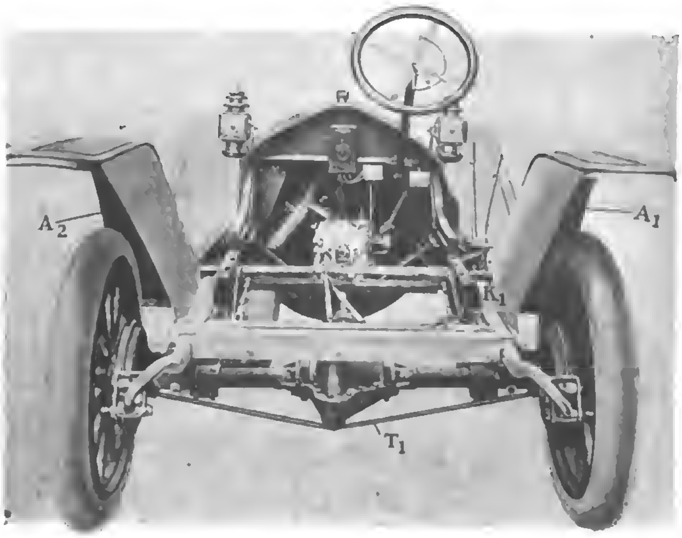

Fig. 7—Rear view of car, presenting live rear axle, method of trussing, and general accessibility with facilities for getting at bevel drive.

and the cams are integral, while the material used is cementing steel and the cam faces are glass-hard.

The connecting rods R17 and R18, as shown in the section, are drop-forged from special steel and the bearing surfaces at both ends are adequate to assure long life. The crankshaft C15 is of high carbon steel, cut from a billet of crankshaft steel, and after rough machining is hardened and ground. The main bearings M2 and M3, as shown in the section, indicate that there is a main bearing on either side of each pair of cranks, and the projected area is such as to assure good running conditions. The journals are of die-cast nickel babbitt, which is regarded in engineering circles as superior for the purpose.

The question of lubrication is of the greatest importance, and the level O1 is maintained by the oil pump O2, and all excess oil drains back to the oil basin B3, while in the process it is filtered through the strainer S11; the plug P7 is available for the purpose of draining the system out, or lowering the oil level. In view of the construction, which places the rocker arms outside, on top of the cylinders, the designer considered it necessary to carefully provide for the proper lubrication of the rocker arm bearings, and this is accomplished by making the shafts on which the arms oscillate hollow. These shafts are plugged at each end, thus forming an oil reservoir, and oil, which is fed from a spring oiler at the top of each rocker arm, maintains a profuse state of lubrication at all times. Small oil passageways are provided so that excesses of oil pass to all bearing points, which are at four places, including the pushrod bearings at the lower end of the rocker arms. Noise, which generally follows wear, is thus aborted, simply because the parts do not generate lost motion.

How the Power Plant Is Made Self-Contained—The rear end of the crankshaft, as the section (Fig. 3) depicts, is provided with a flange F4, which engages the housing H2 of the multiple disc clutch, and the discs D1, D2, etc., are alternately keyed to the driving and the driven members, respectively, so that when the spring S12 is free it presses the discs into intimate contact and the clutch is then capable of transmitting the torque of the motor to the transmission gears. To release the clutch pressure is applied to the pedal P8, actuating the arm A1, the rounded portion at the end of which engages the pocketed face of the thrust-block T1.

The selective three-speed (and reverse) transmission, as it is presented in the section (Fig. 3), shows the lay-shaft S13 below the main shaft S14, and since the drive is "direct on high gear" engagement is made by means of the internal gear G1, with the pinion of the master set G2, which master pinion meshes with the gear G3 to impart motion to the lay shaft. For the remaining speeds the sliding (sleeved) gears G1 and G4 engage their mates on the lay shaft, in response to the demands of the driver, who manipulates the side-lever for the purpose.

Mention of Some Important Details—The telescoped bearing B4 is long, and a ball thrust B5 takes care of the endwise component. The outboard bearing B6 is very liberal indeed, and the stub-end of the shaft, where it engaes the universal joint S15, is splined for a long key K1. Lubrication at this point is well cared for, and by means of the passageway P9 excesses of oil run back into the case. While the front end of the motor is suspended by arms to the side members, the rear suspension is, as shown, at a point with a spring S16, which is placed to impart flexibility. The crossbar C16 is of the channel section and liberal in view of the load.

Fig. 4 is a cross-section of the motor, and in view of specific references to the several parts, as made in Fig. 3, it is offered as showing the clamping means C1 of the upper end of the connecting rod. Flat packing P1 under the case C2 of the bevel-seated valve V1, and the virtue of this method of packing the cage will be seen at a glance, it being the case that expansion is rendered impotent thereby. A little flat spring S1 back of the case C2 prevents the same from working around and aids in assembling.

The cam C3 is of good shape and the roller R1 is forked into a supplementary lever L1, with a fulcrum at F1. This construction assures noiseless performance, since the lifts have but a thousandth or two of clearance, and this distance is below the noise point. A valve V2 controls the supply of oil to the respective cylinders, and by adjustment provided it is possible to regulate at will the supply of oil to each cylinder.

The breather B1 has a cap C4 and a baffle B2 to prevent oil from splashing up and out. The cover C5, over the hand-hole, is provided with a packing P2 and a screwed-on handle H1 to make it tight. It is quick to detach and virtue resides in the plan. The main oil channel C6 shows plainly in this section and the individual oil feed F2 is also plainly in sight. The cross-section of the oil basin B3 offers evidence of capacity, and the oiltight joint J1 is well worth more than passing notice.

Referring to Fig. 5, it will be observed that the crankshaft is suspended to the top half by bearings which are formed in the ribbing system, and the two intermediate bearings B1 and B2 arc provided with caps C1 and C2. In the lower half, which is shown below, the crankshaft is carried by outboard journals J1 and J2, and this view presents further evidence of the method of oiling, with the oil well W1 formed in the bottom of this half of the case. The details of the crankshaft, connecting rods, pistons and rings, are clearly depicted in Fig. 6, and in view of the specific references in Fig. 3 it will not be necessary to more than point out that the flange F1 is placed at the rear end to transmit the torque of the motor to the clutch rather than at the flywheel, which, in a six, is relatively small and unimportant, it being the case that the increments for torque are overlapping and variations are therefore less violent.

Remaining Important Chassis Features—Fig. 7 is of the chassis looking from the rear, and the live rear axle is clearly depicted. The kick-up K1 of the side members shows, and the aprons A1 and A2 of the mud-guards offer, evidences of careful attention to details. The rear axle is trussed T1 to relieve the tube, and a cover C1 makes it easy to open up and examine the bevel drive. There are other features, of course, but they will appear at a glance, unless it is to point out that the selections of material, in the various important parts, is scarcely to be thoroughly well appreciated, since the earmarks of quality, when reference is had to material, are not as surface indications, nor to be seen through varnish. The makers, realizing that future success, which is the matter of moment, depends, to a vast extent, on quality of material, which has been given good attention.

The finished product is delivered to the purchasers either with roadster or pony tonneau body, the color scheme being deep, rich, royal blue, with light cream striping, wheels natural wood, finished with red spiking. Upholstery is in best hand-buffed leather with best hair filling and evidences of superior workmanship. The equipment includes two large headlights, two (side) square oil lamps, tail lamp, horn, jack, and a full set of tools, the whole accessory equipment being of a high grade, and especially selected to suit the car as a whole.

In the roadster accommodation is for two persons, but the pony tonneau has comfortable seating capacity for four persons, and the side entrance, which is provided with a door, is wide. The price of the roadster is $1,700, the pony tonneau bringing a little bit more, namely $1,800.

NEW FRENCH SMALL CAR FOR ONE PASSENGER

PARIS, Dec. 10—In a densely populated country such as France or England many a doctor, commercial traveler, road surveyor and others have objected to be obliged to use a two-passenger automobile, one seat of which was never occupied. There appeared to be a market for a one-man machine, as economical to run as a motor bicycle, but with all the comfort and road ability of a complete automobile.

A machine of this type has just been placed on the market under the name of the Zebra. Except that it has only room for one passenger and has very small dimensions, there is nothing startling in its construction. Its general design, in fact, is most conventional. A pressed-steel frame, dropped to place, the body low, carries a single-cylinder motor of five horsepower under a bonnet in the usual position. The motor has mechanical valves, thermo-syphon cooling through a tubular radiator, and relies on a high-tension magneto entirely for its indespensable spark. The gasoline and oil tanks are mounted on the dashboard, with feed, of course, by gravity with suitable means for proper control and a multiple disc clutch connects the engine to the sliding-gear set, having three speeds and reverse, and final drive is taken by a propeller shaft to rear live axle. On such a light production there is no necessity for torque rods. Brakes are on the rear-wheel drums and are enclosed, with a foot brake on the pulley at rear of the gear box. The steering column, instead of being on one side, is placed in the center, with the brake and change-speed levers in the usual position. Completely fitted with a two-seated body and hood the car weighs 660 pounds. Its speed on the level is 25 miles an hour. Although a very well-finished job mechanically, the small car has the defect of not being sufficiently fitted up in details for the class of users it is intended to serve. The man requiring a one-passenger car generally uses it from eight to ten hours a day, and in consequence calls for a considerable amount of protection not only for himself, but for the organs of the car as well. In this respect the small automobile is rather defective. It is intended to place them on the market in large numbers at $500 complete. The prospects are that the venture will meet with success, the project being in live hands, and all efforts dating from the ground up.

The Zebra, a French Car Designed for One Passenger

Operating Side of the Single-Cylinder Zebra Motor

INDIRECT GEARING NEGLECTED

Reluctant as some may be to believe it, fashion still plays a large part in automobile design, and only too often causes the neglect of constructions which are essentially good. That type of gearbox in which the drive is indirect on the high gear affords an example. This gearbox was used on all the earlier machines, which of course were rather low in power, and gave good satisfaction.

With the increase of power which enabled cars to run for the greater part of the time on the high gear came the invention of the direct-on-high gearbox. For high-powered cars this deservedly became popular; when the high gear was in continuous use, the direct drive gave more power and less noise. But the fashionability of this design on high-powered and high-priced machines led the makers of machines of low power and low price to adopt it, merely as a talking point. To such a degree has this been carried that to-day a thorough search among the specifications of foreign and American cars reveals not a solitary adherent of the indirect system.

Surely this is not as it should be. The indirect system has advantages susceptible of mathematical proof, which are longingly recalled by veterans of the steering wheel. These advantages are most weighty on commercial vehicles and on small runabouts and touring cars, which are becoming more popular now that the craze for high power has died away. The indirect drive deserves consideration by every designer of these classes of automobiles.

In the indirect drive gearbox the power is transmitted through one pair of gears on each of the forward speeds, and through two pairs on the reverse. In the direct drive gearbox no gears are in mesh on the high gear (or whichever gear has been selected for the direct drive), but two pairs of gears are in mesh on each of the other speeds, and three on the reverse. As a certain percentage of the original power is lost in each pair of gears, it is evident that the direct-drive type has a very high efficiency on the direct-drive speed, and a rather low efficiency on the other speeds. The indirect-drive type, on the other hand, has practically the same efficiency on all speeds, the figure being between the highest and lowest of the other type.

For cars which are intended to run practically all the time on high gear, the direct drive is therefore the better; when they are momentarily compelled to use the lower gears, five per cent. more or less power means little to them. But the high-gear car is not as popular as it was. The public has learned that the automobile is a piece of mechanism, subject to the laws of mechanics, and that its changes of gearing do no more than adapt it to do its work in the most economical way.

For low-priced cars the indirect system has the great advantage of simpler and less expensive construction. A three-speed selective direct-drive gearbox usually has eight gears, counting the reverse pinions, and two dog clutches for the direct drive. The indirect box also has eight gears, but eliminates the dog clutches. The direct gearbox has three shafts, necessitating six bearings; one of these must be an "inside" or "concealed" bearing, which not unfrequently is made too small for its work. The indirect box, on the other hand, has but two shafts and four bearings, and costs much less to manufacture.

AMERICA AND THE SLOPING BONNET

Of all the foreign ideas from which we have in time past borrowed freely, one—and a very prominent one at that—has never found much favor on this side, at least not enough to warrant its adoption. By this reference is had to the sloping bonnet, or, more correctly, the dashboard location for the radiator, the shape of the bonnet being immaterial.

At present this is meeting with more favor than ever before in France, all of the highest grade cars being built in this way. In England, the idea has been adopted broadcast (with the revocation of the Renault patents), and no less than a half dozen of Britain's best cars will be so built in 1910.

In this country, on the other hand, the idea has never taken well, and to-day, with perhaps one noticeable exception of recent date, the American manufacturers stand just where they did several years ago on this subject. And yet, this design has much to commend it, the air resistance is slightly reduced, the design lends itself to simplification in the form of thermo-siphon cooling, the delicate radiator is removed from harm's way, the engine as a whole is made more accessible, and the weight distribution is perhaps improved.

With all these weighty arguments in its favor, and some others of lesser weight, why is it that the American manufacturer has not been inclined toward it, or why has the ultimate consumer, the buyer, not taken to this form? This is a question which is hard to answer, in the light of either past practice or present-day tendencies.

E-M-F AND STUDEBAKER INTERESTS ARE AT VARIANCE

DETROIT, Dec. 13—One of the bitterest legal battles the automobile industry has ever known is promised as a result of the summary action of the E-M-F Company in rescinding the selling agreement entered into with the Studebaker Company last April, and the open declaration of war by both the interested concerns. An imposing array of legal talent has been engaged by the warring factions, and official assertion is made that there will be no truce declared until the aid of the highest courts has been invoked, if such a course becomes necessary.

The trouble arose when President Walter E. Flanders, of the E-M-F Company, wrote the Studebaker Company last Thursday, notifying the South Bend concern that all contracts and agreements made and entered into whereby it was stipulated and agreed that the Studebaker Automobile Company should act as sole distributor of the products of the E-M-F Company would be treated as rescinded and annulled by the latter company. The reasons given by Mr. Flanders for this action were because, he alleged, the Studebaker Company had refused and neglected to take and pay for the number of E-M-F "30" cars ordered during the months of October and November; because of alleged failure to give any valid reason or excuse for such nonperformance of the agreement or any assurance that the expressed conditions would be lived up to in future; and because such action evinced an intention not to perform the contracts and agreements existing between the two concerns.

It was further charged that instead of establishing a fair and uniform line of discounts dealers were forced to handle the E-M-F products on discounts unfair and unprofitable; that the popularity of the E-M-F line was used by the Studebaker Company for forcing its products upon dealers if they desired to get the agency for E-M-F cars; that the Studebaker Company committed a grievous commercial blunder in announcing through the public prints that there would be no 1910 model of the E-M-F "30" car manufactured, when as a matter of fact a new model, differing in several important features from its predecessor, had been brought out; and finally that through its advertisements the Studebaker Automobile Company misled the general public into the belief that it owned a controlling interest in the E-M-F Company, it being alleged that this confused agents and buyers and injured the reputation of the product.

A fac-simile of this letter was published broadcast by the E-M-F Company, and brought officials of the Studebaker Automobile Company to Detroit on a jump, with the declaration that they had fulfilled their part of the agreement, that they regarded it as valid and in force, and that they stood ready to go into the courts and fight for what they deem their rights. Officials of the company declared that the fulfillment of the agreement would be insisted upon to the letter, and that all agents and customers would be protected regardless of cost.

As a preliminary to the war that has been declared, the Studebaker Company has retained the legal services of John S. Miller, of Chicago; Otto Kirchner and Gen. Henry M. Duffield, of this city, as special counsel. Besides these there were present at the council of war held here Scott Brown, general counsel of the Studebaker Company; Frederick S. Fish, chairman of the executive committee; Clement Studebaker, treasurer, and Hayden Eames, general manager of the company.

"The Studebaker Company has observed and has not broken its contract with the E-M-F Company," said Attorney Miller, at the close of the conference, speaking officially. "It has established throughout the country selling agencies to the number of several hundreds for the handling of the E-M-F car. It has expended in exploitation of the car and in agencies and facilities several hundred thousand dollars. It has also made sales of the car to be delivered to the extent of hundreds of thousands of dollars. The Studebaker Company has never failed to pay for cars and the E-M-F Company owes a large amount of money under the contract. The claim that the Studebaker Company has failed to take cars required by the contract is untrue. The E-M-F Company has not yet manufactured or had ready for delivery the number of cars it claims the Studebaker is in default of taking. The Studebaker Company has taken all the cars it is obligated to take, and stands ready to take and pay for all such cars in the future."

Officials of the E-M-F Company, just as positive in their assertions that the terms of the agreement have not been carried out, and insist that they will proceed to handle all sales direct hereafter.

Trouble has been brewing for some time, in fact almost from the day the selling arrangement was effected by the two concerns. Of late, however, the situation has become more acute, finally leading to the open rupture caused by Mr. Flanders' drastic action.

The union of the two companies last April was one of the most sensational deals in the history of the automobile industry. For the purpose of securing the E-M-F line of cars to add to other models made by them, officials of the Studebaker Company purchased the stock of William E. Metzger and B. F. Everitt in the E-M-F Company, paying a premium of something like 200 per cent. The capital stock of the company was increased from $500,000 to $1,000,000, and in the reorganization three directors were elected from the Studebaker Company. However, the individuality of the E-M-F Company was retained, and a majority of the stock remained in old hands, a contract being made with the Studebaker Company merely to market the cars. All contracts with E-M-F agents were cancelled at their expiration, September 1, last, and the entire output was to have been taken by the Studebaker Company. Because of the number of lines handled by the selling concern, as well as for other reasons, the arrangement became unsatisfactory, and the E-M-F Company decided to sever all existing relations and market its own product.

The contract with the Studebaker Company is said to have called for 29,600 of the "30" and "20" models for the year beginning September 1, 1909. It is asserted by E-M-F officials that this number will be greatly exceeded with the increased facilities being installed.

Just what the first step in the legal battle threatened will be is not disclosed. Counsel for the Studebaker Company declines to state what action will be taken, merely asserting that the company proposes to insist upon the fulfillment of the selling agreements, and that it will in every instance protect the interests of agents and customers. Meanwhile, the E-M-F Company, having made the first move, is awaiting developments.

What the District Court Has Ruled

DETROIT, Dec. 14—District Court Judge Swan, Monday evening, refused to issue peremptory restraining order asked by Studebaker Automobile Company in its suit against the E-M-F Company to prevent latter annulling the three-year selling agreement between the two companies. The Studebaker Company was given until Wednesday to serve copy of application on the E-M-F, and the latter until Saturday to serve answer. The matter has been set for a hearing next Monday. The Studebaker application stated it had agreed to pay $900 each for E-M-F cars, giving it gross profit of $350; that from April 29 to August 31 it received 4,500 cars, or 1,700 less than it had orders for; for the first year, beginning August 31 last, it was to take 15,200 "30's", and it already has orders for 8,000, exclusive of Flanders "20's". The Studebaker Company claims it has acquired property right which cannot be usurped. The action of the E-M-F directors disrupts business.

S. A. E. WILL HOLD DUAL MEETING THIS WINTER

JUST as in former years, the Society of Automobile Engineers will hold a dual meeting, that is to say, it will meet on Tuesday, January 4, at the Automobile Club of America, at ten o'clock in the morning and hold an all-day session which will include the election of officers for the ensuing year. Papers will be read, discussions will be indulged in, and a dinner will be given at the club, at eight o'clock in the evening.

When the meeting adjourns, it will be until January 13, to meet at the Engineers Club, the idea being to afford its members who cannot attend the meeting which will be held during the A. M. C. M. A. show (the January 4 meeting), a chance to be present at the adjourned meeting which will occur while the A. L. A. M. is holding its show. The adjourned meeting will be quite as interesting, will open at ten o'clock in the morning at the Engineers' Club, papers will be read and discussed, and in the evening a dinner will be given just as at the first meeting, the only exception being that the second dinner will be held at the Engineers' Club.

The meeting this year should prove of the greatest value to the members and the industry as a whole, it being the avowed purpose of the society to deal in the abstract; avoid trade affiliations and serve the whole industry for a broad purpose. The papers in hand are of a high character, the society membership is large and growing, holding in its makeup every chief engineer from almost every company of importance in this country.

In addition to this large contingent of the foremost American automobile engineers, there is a growing representation from abroad, in what is known as International Members, which is a membership contrived by the society to enable foreign automobile engineers to come across with papers; receive the papers of the society and discuss the subjects at length for the common good.' These exchanges of ideas, as interpreted by engineers, will, in the long run, build up the automobile, as a machine, to a state of perfection which is not to be done in any other way. It is of the greatest value to engineers and the industry as a whole, to meet, discuss knotty problems and evolve the right answer. The time must come when the automobile as a machine must be standardized, and who is better qualified than a body of the very engineers who are now responsible for the splendid machines which now afford pleasure and profit to a vast concourse.

GRAND PRIX CALLED OFF—NOT ENOUGH ENTRIES

PARIS, Dec. 9—There will be another year without racing in Europe, owing to the French Grand Prix having failed to fill. When the entry list was closed, the Racing Board of the Automobile Club of France was in possession of twelve cars instead of the forty-five it had fixed as a minimum for the holding of a pure speed test next year. The firms that had decided to show their speed ability under the no-limitation rule were Benz, De Dion Bouton, Rolland-Pilain and Hispano Suiza. One of these firms, the De Dion Bouton Company, had only entered because of the personal conviction of the Marquis de Dion that it was a mistake on the part of the French manufacturers to allow the automobile industry to become nothing more than an industry, as it is tending to become through the absence of racing and shows. Three or four firms failed to send in their entry fees because of the conviction that the necessary forty-five cars could not be obtained.

There appears to have been a belief among the members of the Racing Board that the necessary forty-five cars could be obtained, for before the race was definitely announced personal inquiries were made in all the factories and the promise of forty-two cars was made. Thus it only needed a few foreign entries to obtain what the club considered a necessary minimum. After promising, however, the big firms banded themselves together against any race and the enthusiasm of the smaller constructors quickly fizzled out. Belgium has come forward with the promise of two races on the famous Ardennes course, one of them to be for limited bore and the other for unlimited cars, but in view of the French refusal to take part in any speed event it is very doubtful if she can carry it through on her national resources.

The abandonment of the Grand Prix doubtless carries with it the death of the proposed aeroplane race from Dieppe to the English coast and return, which was to be one of the items of a week's sport in Normandy. The club was only disposed to undertake this if its automobile road race became a reality. This having been killed, it looks upon an aeroplane race alone as rather outside the field of its activities. The only hope of it being held now lies in the towns of Dieppe and Brighton taking it up. As the event would attract spectators in thousands from all parts of the world, there is a possibility of the townships undertaking the cross-Channel flight programme.

Since the abandonment of the Grand Prix the committee of the Automobile Club has agreed in principle to organize next year an aeroplane race from Paris to Brussels, either in a single journey or in stages. The distance by road is practically 200 miles; thus it would be possible, with a light following wind, to make the flight without a stop. Brussels has been selected as the finishing point of the flight by reason of an exhibition which will be held there next year. A better choice might have been made, for the northeast of France is a manufacturing district having very few attractions for the automobilist, while the roads, especially in Belgium and on the French frontier, are far from being the best in Europe.

EX-CHAIRMAN HOWER GETS TESTIMONIAL

BUFFALO, N. Y., Dec. 11—At the Automobile Club of Buffalo last Monday evening Frank B. Hower, former chairman of the Contest Board of the A. A. A., received a chest of silver from the directors of the national organization. It was intended to present the gift to Mr. Hower at the A. A. A. annual meeting in New York, but the plan fell through owing to the absence in the West of the intended recipient.

Chairman George C. Diehl of the Good Roads Board made the presentation speech. Mr. Hower was the most surprised man among the 350 members of the club who were present. His speech, thanking Chairman Diehl as the representative of the A. A. A. was brief, but his manner expressed plainly his pleasure.

KENTUCKY TO CELEBRATE GOOD ROADS LAW

LOUISVILLE, KY., Dec. 13—Arrangements have been completed for a monster banquet in celebration of the recent victory of the Bosworth-Wyatt amendment to the constitution providing for good roads in the State of Kentucky. Prominent Kentuckians from throughout the State will assemble around the festal board on the evening of December 15 at the Seelbach hotel. Final details for the banquet are being worked out by Julius V. Beckmann, secretary of the Kentucky Good Roads Association; Dr. Ben L. Bruner, Secretary of State, and Sam P. Jones, president of the Commercial Bank and Trust Company. Specially invited guests will number about seventy-five. Among the speakers will be Governor Augustus Willson.

WORK STARTED ON ELABORATE PALACE SHOW EFFECTS

THIS week operations were begun on the interior decorations of the Grand Central Palace, New York City, for the Tenth International Automobile Show which opens on New Year's eve, under the management of the American Motor Car Manufacturers' Association. Unitt & Wickes, the official decorators, started a force of 125 artisans at work on the trellis garden decorative effect which will be used for the first time in a New York automobile show.

Decorative Plan of Main Hall, Grand Central Palace

While past automobile shows in New York have been elaborate in decorative effects and have given the gorgeous machines and polished chassis an excellent setting, the trellis garden decorative scheme will linger long in the minds of the public for its simplicity, while it will be impressive and totally different from any preceding show.

Heretofore it has not been possible for the decorators to get into the Palace so far in advance of the show, but this year all work will be completed before the private view at three o'clock, on Friday, December 31.

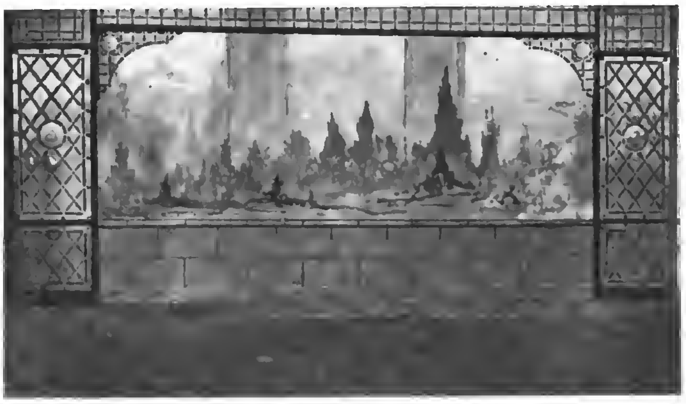
The work of transfiguring the first gallery has already been begun and as soon as this is completed, the artists and carpenters will start work on the second gallery and will then give their attention to the main exhibition hall. Special attention will be given this year to the ceilings under the two balconies, which, heretofore, have not been given much attention by the decorators, but Unitt and Wickes have conceived an excellent decorative effect which will completely hide from view the previously barren ceilings.

One of the most spectacular features of the decorative scheme will be a huge electrical marble fountain stationed at the end of the main hall where last year's statue of Age Instructing Youth was erected. The base of this fountain will measure 16 feet, and it will be over 14 feet in height. Back of the fountain will be an immense plate glass mirror, and surrounding the two will be a beautiful peristyle of green trelliswork, 40 feet in length by 25 feet in width. At the base of the fountain and surrounding the peristyle will be planted low-growing trees, shrubbery and potted plants. The fountain itself, which involves some cunning mechanical ideas, will be operated by a rotary pump and the electrical effects will be produced by a combination of colored mirrors and electricity, which it is expected, will excel anything of its kind ever seen in this country.

Another striking effect which will greet the visitors, even before they enter the building, will be a beautiful porte cochere of green trellis work and frosted glass, which will be illuminated at night by hundreds of parti-colored electric lights, and the whole surmounted by a reproduction of "Miss Liberty at the Wheel" which is also outlined in electric lights.

One of the decorative schemes which will add unusual attractiveness to the Palace will be 100 paintings, measuring 30 by 15 feet in dimensions. These paintings harmonize with the regular trellis scheme and depict various garden and country scenes. Each will be surrounded with lattice work so as to give one the impression of gazing upon midsummer scenes, which will be a marked contrast to the climatic conditions outside of the Palace. The paintings are now being placed in position and will extend around the entire inside of the main floor and the two balconies.

Briefly, the color scheme and decorative effect for this year's show will be nile green lattice work on a soft caen stone background, while the roof will simulate a large trellis arbor hung with grape vines, through which the blue sky is faintly seen. The whole is softly illuminated by scores of immense electric lights, which are hung by chains from the roof of the arbor.



One of the 100 Paintings with Trellis Effect Used

The signs, too, have been specially designed and the names of the various exhibitors will appear in raised gilt Egyptian letters on a green ground surrounded by the usual lattice framework. This idea will be followed all through the main floor and the two upper galleries, except in the central court on the main exhibition floor where trellis standards surmounted by illuminated alabaster signs, will be employed.

DAZZLING DISPLAY OF TROPHIES AT GARDEN SHOW

RACING trophies, great and minor, naturally increase in number each year, but 1909 has been an unusually active one in automobile contests and the aggregate of cups and things now in the hands of motor car manufacturers and agents is enough to make a solid silver monument of heroic size to the Hon. Wm. J. Bryan, or some other man deserving such a fate.

A fine display of these automobile trophies will be made collectively at Madison Square Garden during the week of the Tenth National Automobile Show, January 8-15, and the public then will have the first good opportunity to see the prizes of which it has heard a great deal, assembled all under one roof and in a group and displayed with an amply attractive setting.

The show committee has arranged to make this display of cups, placques, medallions, etc., a feature and a special department of the show. A big case will be provided for the trophies and they will all be ticketed and a pamphlet furnished telling the details of each trophy, its cost, history, etc., and by whom it was won. Big and little, there will be scores of prizes in this loan collection.

Prominent will be the classic Vanderbilt Cup that was won by Harry F. Grant in the Alco; this will be loaned by the American Locomotive Company. The Glidden and Hower trophies, both awarded to the Pierce-Arrow Motor Car Company, are objects of perennial interest, also, and these will figure conspicuously.

Lozier Motor Company will contribute the handsome trophies won in 24-hour races by their six-cylinder car and the splendid statuette won in the Long Island Motor Hunt. The Indiana trophy, the Massapequa Cup, the Merrimac Valley prize, and the Detroit trophy, won in the Glidden tour, will be among the many exhibits made by the Chalmers-Detroit Motor Company. Dewar Cup, awarded by the Royal Automobile Club, of London, in its standardization test, will be loaned by the Cadillac Motor Car Company. The Knox Automobile Company and several others, also, have declared their intention to participate and it is quite possible that some of the recently admitted members of the Association of Licensed Automobile Manufacturers, who will not have any cars on exhibition, will be represented at the show in this display of trophies.

PREPARING FOR THE SALT CITY'S BIG SHOW

Syracuse, N. Y., Dec. 11—The next automobile show under the direction of the Automobile Dealers Association of Syracuse, it was announced this week, will be held in the State Armory from March 14 to 19, inclusive. The dates follow immediately upon the heels of the Boston show, which the Syracuse dealers consider a most opportune time.

The directors of the Dealers Association have been holding meetings at the Hotel Yates this week and starting active preparations for the exhibition, which they claim is going to eclipse anything outside of the New York shows. It is to last two days longer than that of last year and much money will be spent in decorations and illumination in an effort to make the big Armory as beautiful as possible. Those at the conferences included President C. Arthur Benjamin, Vice-President H. D. Van Brunt, Secretary M. W. Kerr and C. H. Norris.

From a complete directory of dealers in Syracuse, prepared at the office of the Automobile Club of Syracuse, it is shown that there are no less than 35 makes of cars sold by eighteen dealers. Since last December the number of dealers in this city, and the number of makes of cars represented, have almost doubled. This is representative of the prosperity, which is everywhere evident in the Salt City, not alone among the dealers and repair men, but at all of the factories as well, most of the latter being now at work nights as well as during the entire day.

SIMMS VIEWS SITUATION WITH OPTIMISM

New York City, Dec. 11—When interviewed by a representative of The Automobile here to-day, Frederick R. Simms, of London, Eng., expressed himself very optimistically on the present situation, both as to automobiles, and what is more close to him, as to magnetos. Mr. Simms was in the city for about a week in connection with the new branch office which he has just established on Broadway to supply the American trade with Simms' magnetos.

For the present, the business will be confined to the exportation of assembled magnetos, followed very shortly by the shipping of parts, which will be assembled on this side (the duty on parts being less than on whole machines). Ultimately, however, the intention is to establish an American factory not far from New York City, where the magnetos will be manufactured complete from the present specifications.

Just at this time, the English and Continental demand for the product is such that the works at Kilburn in London, turning out 600 magnetos per week, is unable to supply the demand. To relieve the situation there, a factory addition is now under way, which will be occupied by March 1. This addition will raise the output to 1,100 machines per week.

On the subject of the present prosperity, Mr. Simms expressed some interesting ideas. He thinks that the present American situation will be continued without change for about two years, or three at the outside, when factory outputs here will have increased to such an extent that overproduction will have taken place, and that the automobile industry in this country then will pass through a crisis, the extent and seriousness of it depending wholly upon the extent of overproduction.

Relative to the other side, and speaking on the same subject, he voiced the opinion that in England, France, Italy and Belgium automobile firms have passed through their critical period and are now on the recovery. England, in particular, coming into her own this year, in connection with the very successful Olympia show which has just closed. Germany, he says, is just emerging from her critical period.

Aeronautics have experienced a great boom on the other side, far greater than can be realized over here, where so little has been done. He said advisedly that the majority of automobile and engine builders in England and France are doing something in this line, either a complete machine or a light engine. The latter have brought a demand for an especially light magneto, and his company is making one, in which the weight is reduced by half or more. His prediction is that in five years aerial machines will be more common that automobiles are now, and that in the meantime, the Atlantic will have been crossed. On the subject of crossing the water, the machine to accomplish this would be a combination of dirigible and aeroplane.

One interesting point which he made was that double ignition, or, as it is often called, dual ignition, is losing ground very rapidly on the other side, the magneto being relied upon for all purposes, even to starting.

ALDEN SAMPSON MANUFACTURING COMPANY WILL CONTINUE

When on December 5, at Pittsfield, Mass., Alden Sampson was laid to rest, the automobile world lost an ideal pioneer, one of its most accomplished engineers and a pillar of stability, of which there were but a few to conjure by.

It will come as no surprise to those who enjoyed the confidence of the late head of this pioneer company that it is to go on; the expressed wish of the late Alden Sampson was that not a moment should be lost; not a thing should be changed; not a single effort should be made which would even tend to dim the luster that clings to a name connected with pioneer effort, original investigation and ceaseless effort in quest of quality—that quality which has the patience to await commercial success as a just reward of its efforts.

Of the trucks made in the past, none was allowed to go into any service for which it was not well fitted, and this year's trucks, of which the company has a goodly number in process, will be placed with the same discriminating care for the future welfare of the company. G. E. Mitchell, long associated with the company, is at the helm, and The Automobile, in expressing its deep regret at the sad event, is compensated in some measure by a situation which assures that the efforts of Alden Sampson will not be lost to posterity.

Specially Fitted Ambulance Built by the Premier Company

NEW AMBULANCE ON PREMIER CHASSIS

Appearing at first glance like a rather long limousine, the motor ambulance just finished by the Premier Motor Manufacturing Company, of Indianapolis, Ind., for an undertaking firm of that city, the A. M. Ragdale Company, has a number of excellent points. It was completed very recently, and put into service for the first time in connection with the Speedway races. The chassis is the same as those used on the regular Premier four-cylinder cars, with a motor rated at 36.1 horsepower.

In the construction of the ambulance, speed, ease in riding and a wish to avoid the morbid curiosity of pedestrians were incorporated in the design. A double floor practically eliminates all sound from the machinery. There is an entrance on each side of the car back of the driver's seat and half of the back of the car opens, forming an entrance for the stretcher, which is of folding canvas design. The canvas is mounted on a folding steel frame, which folds and locks to hold it in place. The stretcher is operated over a roller concealed under the cushions of the rear seat, and fits into steel grooves fastened to the front and rear of the interior of the body. The sides, back and front of the interior are upholstered in black leather. There are two folding chairs, one of which is moved to make room for the stretcher, while the other forms a seat for the physician. Half of the rear seat is also available when the stretcher is in use. The double floor in the car also serves for storing the stretcher when not in use, or for storing the extra chair not used when the stretcher is in place.

Dark green is the body finish, needle-striped with red. Each window is fitted with curtains which bear the company's name. When the ambulance is approaching the patient's home or hospital, however, these curtains are raised, thus removing all appearances of an ambulance and assuming that of an elegantly appointed pleasure car.

UNITED MFRS. WILL SUPPLY TRADEMARKS

New York, Dec. 13—Believing that the could materially assist motoring public, dealer and themselves, five of the oldest and best known accessory builders organized some months since a selling and distributing company to be known as the United Manufacturers. The various units comprising this organization are the Jones Speedometer, C. A. Mezger, Inc., Weed Chain Tire Grip Company, Connecticut Telephone & Electric Company and the N. Y. & N. J. Lubricant Company. The principal object of the formation of this selling organization, is primarily to reduce the cost of these accessories to the consumer; to protect the reliable dealer, seeing that he gets a profit that will enable him to give the consumer the best possible service; and protect themselves and the public against shoddy substituting and infringing. The management of the United Manufacturers states that it believes that all fair-minded dealers are opposed to substitution of any standard product by unscrupulous manufacturers, and therefore, the efforts of the United Manufacturers to stamp out this insidious competition will meet with the hearty approval of their customers among the automobilists.

The United Manufacturers announce that they will supply every reliable dealer in the country with a trademark sign of their own. This is rather a novel idea, and will act as a guarantee to all motorists who are seeking their standard products. Of course that economy is made possible through co-operation is obvious. It naturally decreases the cost of production and selling. The savings made possible by this co-operation really go to the benefit of the consumer, and for that reason, the advent of the United Manufacturers in the accessory field is certain to receive the support of dealer and consumer.

WARNER TAKES UP AERO ACCESSORIES

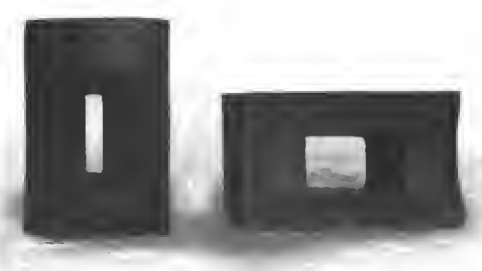
The anemometer, an instrument for showing the velocity of the wind, renders aviators almost invaluable assistance. When stationary, on the ground, it indicates any movement of the surrounding air; when mounted on an aeroplane, it indicates the rate of movement through the air. Although sometimes made in a windmill form, the most common type of anemometer is that with cups mounted on radial arms. The concave surfaces of the cups give the wind a good grip, while the convex surfaces of the cups returning against the wind offer the minimum resistance. In combination wtih the revolving parts some form of speed indicator is used to measure the velocity in miles per hour. This must be suitably calibrated, of course, as on account of friction and other resistances the movement of the cups is slower than the movement of the air.

The Warner Instrument Company, of Beloit, Wis., has found that its magnetic speedometer, as used on automobiles, may be advantageously adapted to anemometer service, and accordingly has brought out a complete anemometer with indicator attached. This instrument is now being sold on a commercial scale. The anemometer measures 17 1-2 inches across opposite cups and weighs, complete, two pounds. The scale is calibrated to read from 0 to 60 miles an hour, which is a sufficient range for ordinary service. One of the anemometers has been in use for some time on the Curtiss aeroplane purchased last summer by A. P. Warner, the vice-president of the company.

VANADIUM STEEL DIES FOR FORGING

A customer of the Pennsylvania Forge Company, of Philadelphia, was using carbon steel dies for very severe service in hot forging and drawing work. These dies were giving an average service of two days, breaking from crystallization or defects in the steel brought out by the constant and heavy blows. It was finally decided to try vanadium steel, in the hope that the remarkable properties of vanadium in retarding crystallization would give the dies a longer period of usefulness.

Some vanadium steel was obtained from the Bethlehem Steel Company and the dies shown in the illustration were made therefrom. The Pennsylvania Forge Company vouches for the fact that the dies were used in the same manner, by the same man and for the same service as the carbon dies. At present they have been in use for over four months, and the illustration shows their condition. The American Vanadium Company, of Pittsburg, gives the analysis of the metal as .75 carbon, .90 chromium and .25 vanadium (contained).



Vanadium Steel Dies That Have Been Used Four Months

Recent Purchasers of Studebaker E-M-F "30's," of Dayton and Springfield, Ohio, Who Have Formed a Studebaker Club

QUAKER CITY TRADE HAD A FINE YEAR

PHILADELPHIA, Dec. 13—Enthusiastic to a degree was the annual meeting of the Philadelphia Automobile Trade Association last Tuesday at its Odd Fellows' Temple quarters. With a sizable balance in the treasury, with fifty-three concerns on the books, and with the success of next month's show already assured, the optimistic spirit that prevailed was not to be wondered at. The past year was the most successful ever experienced by the local automobile trade. A careful estimate indicated a one-third increase over last year, with more than 3,000 cars disposed of for local use alone, not to mentioon upward of 1,200 more distributed to agents in this territory through the various factory branches located here.

The report of Secretary Beck showed fifty-six concerns engaged in the selling of automobiles, of which fifteen were branch houses and forty-one agencies. Twenty-one of these concerns remain unrepresented in the association. The report also showed twenty-eight accessories jobbers and retailers, twenty-one tire houses and seventy-two garages. All of the members present reported the outlook excellent for 1910 as the biggest business year in their history.

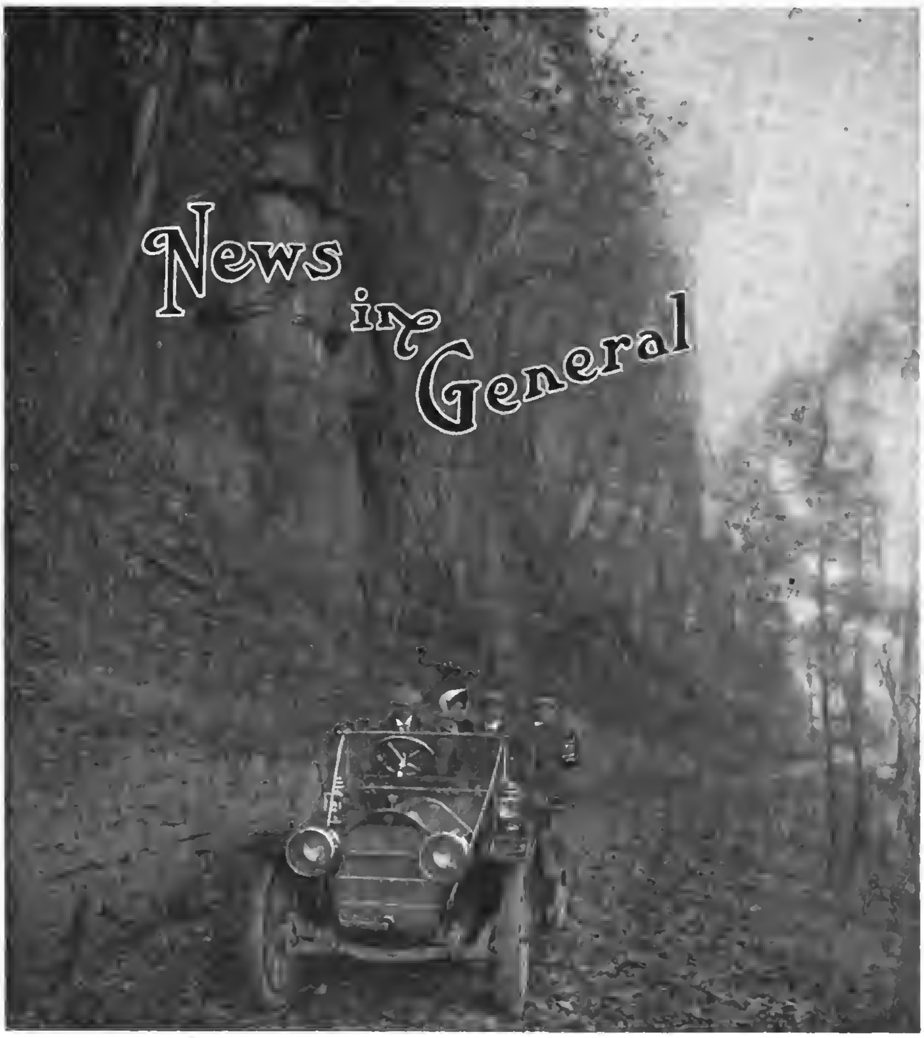
In that section of his report which referred to the coming show in the Third Regiment Armory, Secretary Beck was particularly enthusiastic. Not only had all the available space for the first week been preempted, but that for the second week (which it had been the original idea to devote almost entirely to an exposition of electrics, commercial vehicles and accessories) was almost gonc, the large number of left-overs from the gasoline pleasure class which had been assigned the first week taking up more than half of the second week allotment. An air navigation annex will be a feature of both weeks, whilc the electric display promises to take on the proportions of a national exhibit, as an arrangement has been entered into with J. C. Bartlett, of the big Woods garage, at a minimum of expense, whereby salesmen and demonstrators will be provided for out-of-town manufacturers who may desire to exhibit their cars, which will be received, taken care of, and shipped home after the show. This scheme has already borne fruit, no less than eight electric concerns having applied for space during the second week.

The annual election of the association resulted in the choice of the following officers to serve during the ensuing twelve months: President, J. A. Wister (Elmore); vice-president, H. B. Larzelere (Chadwick); treasurer, W. J. Foss (Pierce-Arrow); board of directors, L. C. Block (Ford), A. E. Maltby (Winton); committee on admissions, Fred C. Browning (Autocar) and F. C. Vanderhoof (Olds-Oakland).

INSURANCE MEN INDORSE AUTO ENGINE

LANSING, MICH., Dec. 6—That the insurance companies would have fire departments equipped with automobile engines if they had their way is shown by the endorsement of the work of the Lansing, Mich., machine by the Michigan Millers' Mutual Fire Insurance Company. The village of Bath, about 10 miles distant from Lansing, was nearly destroyed by fire last week, and would have been entirely wiped out but for the prompt assistance of the Lansing auto engine, which made the run in a few minutes, a feat impossible for an engine drawn by horses. The Millers' Insurance Company was enthusiastic in praise of its work. As insurance companies seldom grow enthusiastic about anything of this nature, it is taken as a huge compliment to the automobile.

Nearly Completed Four-Story Addition to the Plant of the Moline Automobile Company, Moline, Illinois



Along the Face of the Palisades in a Simplex Car

Industry Needs Machinists—Robert Jardine, who is now superintendent of the Royal Tourist Car Company's plant, at Cleveland, says that the greatest need of the automobile industry is a supply of intelligent machinists. The average man now learns to operate but one machine, and as a result, if a man cannot be used on that particular one he is, as a rule, temporarily unavailable. All-round men are badly needed. The trouble seems to be that young men who have passed through the high-school will not enter a plant as apprentices, and with others who have not had that much education the operation of a machine must be learned by rote. Naturally the latter kind are not found very adaptable.

Bergdoll Buys a Blériot—Louis J. Bergdoll, the Philadelphia automobilist, has purchased a Type XI (cross-Channel) Blériot monoplane, and will attempt flights shortly. He purchased the machine from Rodman Wanamaker, the direct importer, and has had it set up in his garage. Some interesting details are given of the construction of the propeller. It is made by Chauvière, of Paris, 6 feet 10¾ inches in diameter, and weighs but 9.9 pounds, although revolving at a speed of 1600 revolutions. The wood is selected French walnut, laminated, and the laminæ are so arranged that the grain extends from tip to tip. The slip is said to be but 15 per cent.

More Electric Stations—Charging stations at frequent intervals are absolutely necessary to convenient use of an electric car, and the interest taken by electric power plants has greatly helped to popularize this type of motive power. According to O. B. Henderson, of the Baker Motor Vehicle Company, many electric plants are realizing the advantages of supplying current for electrics, and in many cases have completely equipped establishments, with expert attendants. They understand that the automobiles use much more current than curling irons or chafing dishes, and that a moderate patronage will more than pay the expense of providing charging facilities.

Apperson Feats in West—During the past summer Harris Hanshue, of Los Angeles, has driven his Apperson "Jack Rabbit" in eight events on the Pacific Coast, and of these has won five firsts and two seconds. In the 50-mile Ascot race at Los Angeles, in which he was unplaced, a tire blew up and tangled a driving chain, breaking it. He won the 150-mile Ascot race, the Pasadena-Altadena and Redlands hill-climbs, and the heavy car classes at Santa Monica and in the Portola race, at Oakland, Cal. The car is now two years old, having been for one year the property of a private owner in Chicago before being taken to the Coast.

Hartford Likes Its Fords—Two Ford runabouts ordered for the use of the fire chiefs of Hartford, Conn., have just been accepted by the commissioners. President Clark, of the fire board, has given a demonstration at the rate of 48 miles an hour. In the purchase of these two cars the city saved over $1,000, as the appropriation was $3,000 and the Fords cost but $1,997. They went into commission on December 12. The Fords previously used by Chiefs Krug and Loomis have made good in every sense of the term. Chief Krug does not think it is possible to beat his old car, and says that if the new one cannot beat it he will retain the old one.

Baseball Celebrities Converted—To the list of baseball celebrities in the ranks of the automobilists have been added Charles A. Comiskey, president of the Chicago White Sox, and "Hughie" Jennings, manager of the Detroit Tigers. Mr. Comiskey purchased a Studebaker-Garford "40," with a limousine body, from the Chicago Studebaker branch just before leaving for his annual hunt on the Mississippi. The Tiger manager got a Studebaker-E.M.F. "30" in Detroit and drove it to his winter home in Scranton, Pa., where he practises law.

Free Half-Barrels of Oil—The following automobilists are now the recipients of half-barrels of Mobiloil, distributed as the result of an ingenious program scheme at the Vanderbilt: Miss Grace Driggs, New York; J. R. Salmon, Boonton, N. J.; R. C. Warner, East Orange, N. J.; C. J. Allen, Moorestown, N. J.; F. S. Hastings, Richmond Hill, L. I.; B. J. Sjaberg, Elmhurst, L. I.; T. N. Benedict, New Rochelle, N. Y.; C. A. Kochlen, Morris Park, N. Y.; C. A. Baker, Richmond Hill, L. I.; B. H. Harrison, New York.

Rambler Wins At Slow Driving—At times it is fully as important to be able to drive slowly on the high gear as it is to drive fast. In recognition of this, at a recent meet in Texas, a prize was offered by H. T. D. Wilson, of Houston, to the driver making the slowest quarter mile on the high gear. Four cars were entered, of which two were disqualified by their inability to travel slowly on high without killing the engine. A Rambler won the event, taking 4 mins. 35 secs. to cover the distance.

Empire Tire Branch in Philadelphia

Under the management of E. B. Richardson a new branch has been opened in Philadelphia by the Empire Tire Company, Trenton, N. J. The office shown above is located at 322 N. Broad street, where a full line of Empire tires is always kept on hand.

Factory in Springfield, Ill.—The Illinois capital is about to acquire its first automobile factory. This is a 500 by 260-foot building of brick and concrete, with saw-tooth roof, now und r construction for the Springfield Motor Car Company. The car to be built in this factory will be a 40-horsepower, seven-passenger, selling, complete with Bosch magneto, top and lamps, for $2,500. It will bave a four-cylinder 5 by 4 3-4-inch motor, 128-inch wheelbase, and tires 36 by 4 front and 36 by 5 rear.

Franklin Family in Vermont—The Proctor family of Vermont, which has for years taken a prominent part in the political and industrial history of that State, owns nine Franklin cars. The first, an 18-horsepower runabout, was purchased in 1906, and was used mostly for trips between the family marble quarries. Recently a 1910 Franklin 18-horsepower runabout was sent for the use of Redfield Proctor, son of the late senator of tbat name. All of the nine are in steady use.

From the Sunflower State—The Stafford Motor Car Company, of Kansas City, has been organized with a capital stock of $100,000, fully paid up, and will take over the property of the Stafford Motor Car Company, of Topeka, which it succeeds. The plant will be moved to Kansas City about January 15. Terry Stafford continues as president, and the same car will be manufactured. Others interested are C. L. and F. C. Merry, W. G. Whitcomb and C. C. Hoefer.

"Seeley Cure" for Autos—The High-Frequency Ignition Coil Company, of Los Angeles, Cal., which makes the Seeley ignition system, says that this ignition bas been adopted by tbe Columbia Motor Car Company, of Hartford, Conn., for use on its 1910 product. In the Ascot Park races at Los Angeles a Corbin car with Seeley ignition took first in a five-mile and second in a ten-mile.

"Silent Sioux" in Waukesha—The "Silent Sioux," a four-cylinder, 40-horsepower car that was built at Sioux Falls, S. D., last season, will benceforth be made in Waukesha, Wis. The concern, of which R. J. Wells is president, bas leased the former plant of the Waukesba Motor Company on North street, and its equipment is now being removed. The output will be increased to ten a month.

"Red Wing" From Minnesota—The Red Wing Boat Mfg. Company, of Red Wing, Minn., has changed its name to the Red Wing Motor Company, and coincidently increased its capital from $50,000 to $250,000. The reorganized company will build automobiles, which, it is said, will be fitted with a modification of the motor formerly built by the company for use in boats.

The Kero-Car from Dayton—Dayton, O., business men are forming the Kero-Car Motor Company to build an automobile driven, as the name indicates, by a kerosene engine. Tbe new engine is said not to be a freak, either in appearance or operation, closely resembling the standard automobile engine. It will burn, however, either gasoline, kerosene or alcohol.

IN AND ABOUT THE AGENCIES

Rushmore Lamps, Berlin, St. Petersburg, Riga and Christiania—The Rushmore Dynamo Works has recently placed agencies in the capitals of Germany and Norway, and in St. Petersburg and Riga, Russia. Branches have also been opened at 1 Crow street, Dublin, and 33 Victoria Building, Deansgate, Manchester, G. B., in addition to the well-established London and Paris branches.

Speedwell and Perry, Philadelphia—Harry L. McCullough has been selected to manage the Continental Motor Car Company, wbich recently secured the Philadelphia rights for the Speedwell and Parry cars. He is carrying on business from Room 1541 Land Title Building, until repairs are completed on the building at 1416 Vine street, just off the "Row."

Peerless, New York City—The Peerless Motor Car Company announces the opening of new salesrooms and offices at 1760 Broadway, near Fifty-seventh street, New York City. This is the splendid new building of the Peerless branch, wbich affords a location and facilities unsurpassed in the city.

Everitt "30," Philadelphia—The W. Wayne Davis Company of Philadelphia, distributors and factory representatives of the Metzger Motor Car Company, makers of the Everitt "30," is carrying on business in temporary quarters at 207 Nortb 22d street, pending the securing of a location on the "Row."

Thomas, Philadelphia—Frank J. Fanning, formerly of the Chalmers-Fanning Company, has closed with the E. R. Thomas Motor Company to represent the Thomas Flyer in Philadelphia. Mr. Fanning already has the local right for the Mercer, built in Trenton, N. J.

Simms Magneto, New York City—An American branch of tbe Simms Manufacturing Company, Ltd., has just been established at 1780 Broadway, New York City, from where the American trade in Simms magnetos will be pushed with characteristic vigor.

Everitt, Detroit—John A. Sibley and W. J. Casterton have organized the Security Auto Company, and will act as Michigan agents for the new Everitt. A garage 60 by 250 feet, on Woodward avenue near Warren, is to be ready by February 15.

Remy Magnetos, San Francisco—The Remy Electric Company has established a branch distributing office in San Francisco, at 170 Golden Gate avenue, where a complete line of magnetos, fittings and parts will be carried in stock.

Continental, Wimbledon, N. D.—The Indiana Motor Sales Company has appointed More Brothers, Wimbledon, N. D., agents for the Continental in North Dakota and part of South Dakota.

Pullman, Birmingham, Ala.—The Pullman Automobile & Supply Company bas been organized, and has arranged for a garage at Avenue C and Twenty-first street, where it will handle the Pullman.

Palmer-Singer and Simplex, Kansas City, Mo.—In the future the Palmer-Singer and Simplex cars will be handled in tbis city by the L. C. M. Motor Car Company, located at 3816 Main street.

Thomas, Boston—C. S. Henshaw, manager of the E. R. Thomas branch in the Hub, has leased a new salesroom at 587 Boylston street, on Copley square, and will take possession December 22.

Velie, Geneva and Oneida, N. Y.—The Kerr-Doane Motor Company, of Syracuse, N. Y., has appointed Baker Brothers, of Geneva, and F. B. Petrie, of Oneida, subagents for the Velie.

Monogram Oil, Boston—The Boston branch of the Columbia Lubricants Company, maker of monogram oil, has removed from 35 Hartford street to new quarters at 1000 Boylston street.

Mason, Shelby, O.—The American Motor and Supply Company, of Shelby, O., has the State agency for the Mason car, and is erecting a fine two-story garage and salesroom building.

Parry, Baltimore—The General Auto Company will be the local representative of the Parry. The firm bas its salesroom at 12 West Eager street. Joseph M. Wright is manager.

Austin, Boston—Tbe Austin Company has been established to act as agent for this car, and has established quarters in the former Kenny-Clark building at 94 Massachusetts avenue.

Howard Rim, Philadelphia—A Philadelphia branch has been opened at 1411 Race street by the Howard Demountable Rim Company, of Trenton, N. J. H. T. Eisenberg is manager.

Continental, Indianapolis—The Reliable Auto Exchange, of Indianapolis, has been appointed Indiana State agent for the Continental, with an allotment of 100 cars.

Marmon, Louisville, Ky.—The Atlas Machine Company, which represents the Empire, has moved to 735 West Market street and assumed the agency for the Marmon.

Overland, Omaha, Neb.—H. H. Van Brunt has obtained quarters on the south side of Farnum street, near Twenty-second, where he will handle the Overland.

Moline, Houston, Tex.—George W. Beardsley, who has a bicycle establishment on Texas avenue, has taken the agency for the Moline.

Demot, Houston, Tex.—The Imperial Motor Car Company, of Houston, has been appointed agent for the Demot in southern Texas.

Corbin, San Francisco—Tracy Holmes has been appointed agent for the Corbin and will open headquarters on Van Ness avenue.

NEW FIRMS IN WINNIPEG

Winnipeg, Man., Dec. 8—Two new concerns have entered the automobile field in this city during the past month, and there is every prospect of a further increase before the opening of the 1910 season, as the Regal Motor Car Company is looking over the ground with a view to the establishment of a branch in connection with its Canadian factory, under construction at Walkerville, Ont.

The Central Garage Company has secured a long lease on the modern garage erected by an English syndicate as a speculation. The building has a frontage of 200 feet on two thoroughfares and is 110 feet deep, the construction throughout being brick and steel. The company has secured the local agencies for the Knox, KisselKar and Oakland.

The other company is the firm of McRae & Breen, a reorganization of the carriage firm of A. C. McRae. They will place on the market the Overland, Detroit Electric and a good line of commercial vehicles. General trade prospects in Western Canada have never been better. The number of orders already placed exceeds last season's total.

TOLEDO, O., AGENCIES FOR 1910

Toledo, O., Dec. 4—Arrangements have practically been completed by the dealers of this city for their 1910 agencies. The following have been announced: Toledo-Mitchell Company, W. A. Kavanaugh, manager, Mitchell; H. J. Adams, Toledo and Fostoria, O., Babcock Electric; Lichtie Auto Company, Cadillac; Olds-Oakland Company, Oldsmobile and Oakland; Gamble Motor Car Company, Baker, Rauch & Lang and Columbia electrics, and Peerless and Stearns; Patterson & Rault, Rambler; Norris-Toledo Sales Company, Demot, Parry and Velie; Wood-Kessler Company, White steam and gasoline, and Black-Crow; Buick Motor Car Company, F. S. Rockwell, manager, Buick; Regal Motor Car Company, W. S. MacMurray, manager, Regal; Atwood Automobile Company, Overland; Twenty-first Street Garage, Detroit electric and Jackson, Stearns and American; Blevins-Studebaker Automobile Company, Studebaker; Dosson Carriage Company, Paterson, De Tamble and Brush; Union Supply Company, Chalmers-Detroit and Hudson; Roberts-Toledo Auto Company, Ford; Banting Machine Company, Whiting and Grabowsky.

MORE NEW BUILDINGS FOR WILLYS

Toledo, O., Dec. 6—With the mortar hardly dry on one addition, President Willys of the Willys-Overland Company has announced that plans are being made for another, on which work will be started as soon as the weather permits. This new department will be used for the manufacture of commercial cars of both the delivery and truck types. Mr. Willys sees immense possibilities in this line and has determined to enter it as soon as possible. Orders are already being taken for delivery on May 1. Specifications have not yet been published.

MAXWELL AGENTS IN OHIO

Columbus, O., Dec. 6—The Maxwell-Briscoe Columbus Automobile Company, of which Frank Corbett is manager, has announced a number of sub-agencies in its territory. They are: E. D. Valentine, Springfield; R. W. Ferris, Mt. Vernon; J. B. Griffith, Jackson; J. W. Patton, Marion; W. A. Biddle, Urbana; R. C. Fulton & Company, Athens; Dwyer Brothers, London; O. W. Bonnell, Delaware; Martin & Michael, Washington Court House; Amos Johnson, Wilmot; F. P. Arnold, Cambridge; W. P. Bletzacher, Lancaster; M. A. Ryan, Circleville, and S. Siegrist & Sons, Coshocton.

The company will move shortly into the new salesroom at 58 East Spring street, which will have a space of 40 by 140 feet for salesrooms and a repair shop 50 by 16 ft.

NEW THERMOID RUBBER FACTORY

Trenton, N. J., Dec. 4—The Thermoid Rubber Company is now occupying its new building, which is devoted entirely to the automobile lines, the manufacture of brake lining, tubing, etc. The building is of brick and steel construction, 120 by 120 feet, and two stories high. The first floor ceiling is 16 feet high, and the second floor 14 feet on the sides, running to 27 feet in the center. The interior walls are painted white and the machinery black. The building is equipped with lockers and lavatories for the workmen.

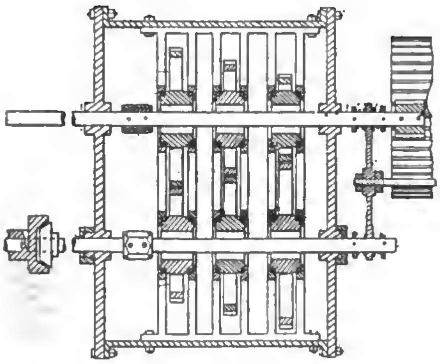
New Brick and Steel Building of the Thermoid Rubber Company at Trenton, N. J.

SOME SELECTED AUTO PATENTS

Issue of August 31, 1909.

932,467. Power Transmitting Device—L. J. Harris, Worcester, Mass. Filed January 10, 1902.

This gear-changing device works, generally speaking, on the individual clutch plan, in which the gears are always in mesh. In all the forms shown in the patent drawings the gearing is of the indirect-on-high type; there are but two solid shafts, the power from the engine being applied to one and the drive to the rear wheels being taken from the other. In addition, the gearing is of the progressive type; the gears must be engaged in their regular order. It will be remembered that the "indirect progressive" was the earliest form of sliding change-gear to be applied to automobile use, and although it has since gone out of fashion, it nevertheless possesses advantages which lead some experts to believe that it will be revived for use on certain classes of vehicles, particularly motor trucks. However, it is probable that the inventor can adapt his gear to the more fashionable direct-drive and selective systems without material modifications.



Harris Individual Clutch Change-Gear

The most noticeable difference from ordinary individual-clutch practice is that the gears not working are not allowed to turn idly. This is accomplished by having the gears on both shafts free, instead of those on one only. Further, it is specified that the gears are actually not in contact with their shafts unless engaged by the clutches. The gears are carried on their own bearings in a separate frame.

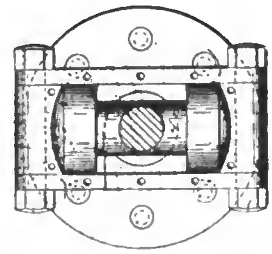
Means of locking the gears to their shafts is provided which has considerable novelty. A hexagonal block of hardened steel is keyed on the shaft. The gears are formed with hexagonal holes through their hubs, adapted to fit the block. By sliding the gears and shaft relatively to each other, the block engages in turn with the hubs of the gears, giving a positive drive. The corners of the block are beveled to guide it into engagement.

The patent covers various combinations of the shafts, gears and hexagonal block, as well as other suitable means, by keys or otherwise, of locking the gears to the shafts as desired. The engaging means, it will be remembered, are provided on both driving and driven shafts. It is possible either to slide the locking devices, the gears remaining stationary, or to slide the frame carrying the gears, the locking devices remaining stationary. The locking devices are suitably cushioned by springs to give smooth action.

Issue of December 7, 1909.

942,087. Universal Joint—Willard C. Lipe, Syracuse, N. Y. Filed November 25, 1905.

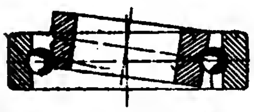
This joint appears to be simpler than many in use at present, and combines both the universal action and the sliding movement necessary to compensate for the variation of distances between centers. It consists of two members to be attached to the two shafts, respectively; two side plates for one of the members and bolts for their attachment. The first member is formed with two projecting arms parallel to its axis, the opposite interior faces of which are formed with concave cylindrically curved surfaces. The two plates mentioned bolt across between the two arms, forming an open-ended socket or rectangular cross-section. The end of the other shaft is formed with a T-head, the ends of the T being suitably rounded and sliding in the concave surfaces of the member on the other shaft. The rotational driving moment is transmitted between the plates which form the sides of the socket and the ends of the T. It is apparent that the device has longitudinal freedom, limited only by the length of the projecting arms of the first member and consequently of the socket.



Lipe Universal Joint

942,392. Ball Bearing—Gustav A. W. Koch, Paris, France. Filed July 14, 1908.

This is a ball bearing of the annular type, and the patent covers especially the method of assembling the same with the balls in place. The bearing is presumably of the "full" type. The patent calls for a ball bearing in which one of the rings forming the races is provided with an "eccentric frustoconical surface" at one side of the raceway to facilitate forcing that ring into its proper relation to the other ring with the balls in place. An additional claim covers "a confining ring for a ball bearing having a concave circular race-way, and a marginal surface on one side of said race-way whose surface is inclined to the cylindrical, the angle of said inclination varying continuously from a certain minimum to a certain maximum."

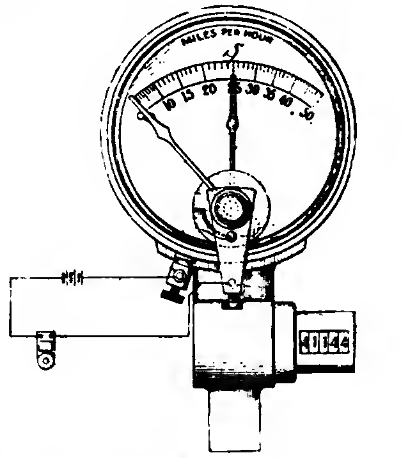


Koch Radial Ball Bearing

942,497. Speedometer Attachment—William R. Harris, Irvington-on-the-Hudson, N. Y. Filed July 28, 1908.

A new field for the inventor's talent has been opened up by the demand in some quarters that automobiles be provided with a device that will show when a certain legal maximum speed is being exceeded. Several devices of this nature have been brought out in England, but this is the first which has come to notice in this country.

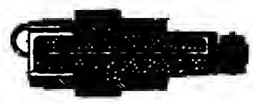
The speedometer itself may apparently be of any ordinary type. It is provided with a second hand, like the "maximum" hand recently brought out, which may be adjusted to any desired position on the scale. This hand carries an electric contact piece connected to one side of a circuit. The speedometer indicating hand carries a similar contact adapted to touch that of the extra hand whenever the figure indicated by the latter is reached or exceeded. The electric circuit of course is provided with a suitable alarm bell which rings when the contact is made.



Speedometer with Harris Speed-Limit Bell

942,567. Automobile Tire—Iva B. Kempshall, Boston, Mass. Filed August 13, 1909.

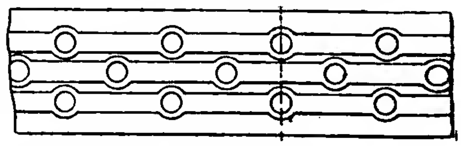
Anti-skid tires are another fruitful field for inventors. This tire is one which has been on the market with considerable success. The patent covers the shape and arrangement of projections on the face of the tire. These are specified as a "series of continuous longitudinal ribs, each of which presents continuous edges around the tire, and is formed with a series of pockets" and a series of continuous longitudinal ribs presenting continuous edges extending around the tire, each of the ribs being formed with a series of enlargements forming protuberances on said edges. These two claims, although embodied in the same patent, seem to cover quite different and distinct ideas in tire construction, as the former, with its "series of pockets" should have a sucking action on the road surface quite different from the effect of the protuberances in the other claim.



Jeffery Non-Sooting Plug

942,646. Electric Igniting Device—Joseph A. and Benjamin A. Jeffery, San Francisco. Filed August 15, 1906.

Although disguised as an "electrical igniting device," this is really only a spark-plug, with an ingenious means for preventing fouling. The claim is for an "electric sparking device with separated terminals, the exposed area of either of said terminals being restricted to a limit where the proximity or surface contact therewith of a medium of lesser conductivity will be insufficient to carry the current without heating such medium to the point of disintegration." In other words, the electric current passing between the points is so concentrated that the "medium of lesser conductivity," that is, the soot or carbon, is simply burned away before it can have any injurious effect. The patent appears to cover some forms of spark-plugs which are at present on the market, although the anti-fouling device is both new and ingenious.



Kempshall Anti-Skid Tire with Ribs

Information for Auto Users

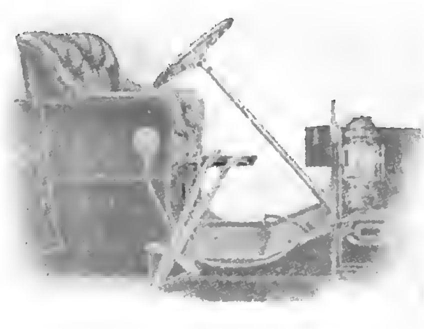
Bi-Motor Wind Shields—These shields manufactured by the Bi-Motor Equipment Company, 177 Portland street, Boston, are in several styles, known under the trade names of the "Boston," the "Hartford" and the "Lincoln." The "Boston" is folding and adjustable. It has no cams, springs or catches, and can be placed in any position with one hand. It cannot be broken by slamming, as it stays in any position in which it is placed. The resistance is adjustable, either for wear or to suit the individual taste. The frame is of 7-8-inch seamless brass tubing, and the glasses are genuine French plate.

The "Hartford" is a drop shield, and is particularly adapted to cars which have the steering wheel so near the dash that there is not room for a hinged shield to swing. The upper glass moves up and down in a vertical position close to the

BI-MOTOR WIND SHIELD, "BOSTON" STYLE

stationary glass. It is made of the same materials as the "Boston" and sells at the same price. The "Lincoln" is a cheaper shield, of the folding type. Its mechanism is different from the "Boston," involving the use of set screws to hold the swinging glass in the desired position. The materials are the same as in the other shields, the lower price being due to the less expensive mechanism. All three shields are made either 36, 39 or 42 inches wide, with 5, 8 or 10-inch mahogany filler boards. Special attention is paid to packing for shipment, to insure reaching the purchaser in good condition.

"Out-o-Site" Seat.—The McKinnon Dash Company, of Buffalo, N. Y., has brought out a simple and inexpensive folding seat with which the capacity of an automobile can be increased in an emergency. It is intended principally for children, although strong enough to support the weight of an adult if necessary. The cut shows it attached between the two front seats, a position which, of course, would be impractical unless the occupant was small enough not to encroach on the driver's elbow



"OUT-O-SITE" SEAT ON A CADILLAC CAR

room. It can also be used in the tonneau, back to back with the front seat, or on the inside of the tonneau doors. It folds flat into the thickness of its own cushion, so would not obstruct the opening of the doors in this position.

The seat consists of a light frame of round steel, handsomely oxidized, which is attached to the framework of the body by four screws, and the seat cushion, also with a steel frame, upholstered in imitation leather. There are no diagonal struts. The seat when open is held in a horizontal position by hook-like extensions of the cushion frame. To close, the cushion is swung up vertically and then dropped down into the supporting frame.

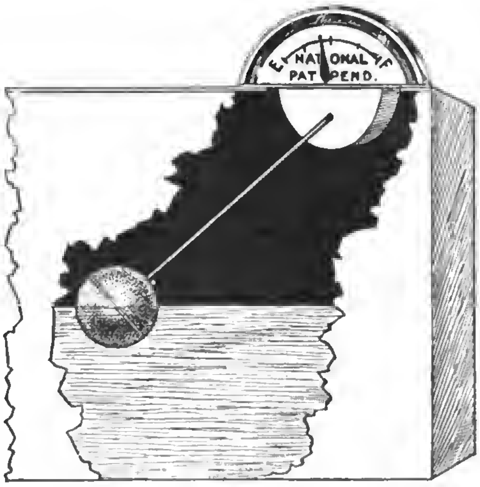
1910 Gabriel Horns—The Gabriel Horn Manufacturing Company, of Cleveland, will continue to manufacture its horns which have given such satisfactory service in the past. In the 1910 models, however, the two lower notes will be operated together, making a perfect chord, which, in combination with the high note, two octaves above, produces a singularly sweet musical effect and also gives great carrying power. The sizes and weights are as follows: No. 2 horn, 2 1-2-inch tube, 30 inches long; weight, 4 pounds; No. 3 horn, 3-inch tube, 32 inches long; weight, 5 1-2 pounds; No. 4 horn, 3 1-2-inch tube; weight, 6 1-2 pounds.

The 1910 valve is the same as formerly except that the lever is made from 3-8-inch stock, and the screws which fasten on the discs are better placed, so as to greatly increase the strength. The valves are made in sizes to fit 3-4 to 3-inch steel tubing and 1 to 2-inch iron pipe. The valve can be used for a muffler cut-out by removing the disc in the main channel.

The Gabriel trumpet is another novelty which this company has recently placed on the market, and which has proved very popular. It consists of four single tubes with a valve on each controlling the tube individually. These are operated by a keyboard carrying four keys. All the ordinary bugle calls can be played on this instrument. The keyboard is also fitted with a small lever which opens all four valves, thereby giving a perfect chord for signalling purposes simply on pressing the foot pedal.

"National" Gasoline Gauge.—For simplicity this gauge will certainly take the prize. It has but one moving part, a bent wire, pivoted, one end of which carries a float and the other the gauge pointer. There are no gears, springs, pulleys, or anything else that could get out of order or stick. The float is of spun brass. The dial is an arc of about 90 degrees, and reads from the side. This makes it easy to see while filling the tank, and at the same time protects the glass from breakage. The dial projects only three-quarters of an inch, so that it will go on almost all tanks under the seat. The gauge body is of brass, nickel plated, and is dust-proof.

Another good feature of this gauge is that it can be adapted to any depth of tank up to 12 inches simply by lengthening or shortening the wire which carries the float. The length of wire for a given depth is specified by the maker. This



FEW PARTS IN THE "NATIONAL" GAUGE

makes easy work for dealers, who do not have to carry in stock different sizes for different tanks. The "National" gauge is made by the National Motor Supply Company, Cleveland, and sells for a very reasonable price.

INDEX TO ADVERTISERS

THE AUTOMOBILE

FRANCE HOLDS A RELIABILITY RUN

BY W. F. BRADLEY

PARIS, Dec. 9—France is holding an automobile realiability trial. It has adopted both the idea and the word from across the English Channel, and explains that the foreign word means "that in which you can have confidence." Thus, as confidence needs to be established more in the smaller types of cars than in their big brethren, the trial has been limited to voiturettes, with dimensions fixed at 4.9 by 5.9 for a single-cylinder engine, 3.9 hy 4.1 for a twin, and 3.1 by 4.7 for a four-cylinder motor.

The reliability trial is simplicity itself; 15 daily stages, totalling 2,000 miles, to be covered at an average speed of not less than 15½ miles an hour, with no other stoppages than filling gasoline, oil and water tanks and changing tires when necessary. As each day's run is finished the car is pushed into a closed garage and locked up until the official starting hour in the morning. Six courses have been selected, but the particular one to be followed is never made known until a few minutes before the start. To come through with a clean score practically amounts to a sealed bonnet competition, but in order not to decimate the ranks too much it is allowed to clean spark plugs, carbureter in case of obstruction, tighten nuts and adjust brakes and driving chains without penalization. Any other work on the car entails the loss of points.

Thirty-three small cars entered for the trials, but on the Sunday morning appointed for the start the number had been reduced to 29 actual competitors, the firms represented being Sizaire-Naudin, Gregoire, Delage, Alcyon, Hurtu, Corre-La Licorne, Barré, Demeester, Doriot-Flandrin-Parant, Turicum, Fouillaron, Rolland-Pilain, and Zenith. This list comprises all of the French voiturette constructors of any importance with the exception of one.

Although the one-lunger has been most highly developed in France for small-car work, it is somewhat surprising to find that they are in a decided minority in this competition. There are only six single-cylinder cars, compared with 23 fours, and no twins. The only firm putting in a full team of single-cylinder cars is Sizaire-Naudin; even they are about to start the construction of a four. Doriot-Flandrin-Parant has one single and two fours, and the others in the one-lunger class are Hurtu and Fouillaron. It would not be safe to conclude from this that the one-lungers are going out of use, but rather that the manufacturers have more confidence in their fours, or prefer to push them in preference to the singles, the public demand for the former being greater.

Delage No. 7, Driven by Haye, Passing the Barre Car in the Climb of the Cote de Bonnieres

From an external examination only it would be impossible for the most expert automobilist to distinguish the ones from the fours. Ninety-nine men out of a hundred would swear, indeed, that the single-cylinder Sizaire-Naudin had a multiple-cylinder motor under its bonnet, while the Doriot-Parant single is an exact counterpart externally of its four-cylinder brethren. If anything, the single cylinders are quieter than the fours, for the former are well muffled, while the latter have that peculiar ring of a small high-speed four-cylinder motor with its exhaust not completely muffled.

Although 15½ miles an hour is all that is required of the cars, no driver is satisfied with such a crawl. On the first two days the average speed of the conservative drivers was 25 miles an hour, while some of the daredevils went very much higher. There was not a single case of failure to make the controls on time, though

Georges Sizaire on the One-Lunger Sizaire & Naudin

Four-Cylinder Zenity—Friction Transmission, Shaft Drive

several failed by reason of minor adjustments which were not allowed under the rules. Although the roads are particularly heavy by reason of persistent storms, it is certain that several will come through with a clean score, and elimination is likely to be caused more by reason of small adjustments than for serious mechanical defects.

One of the most important conditions is that the cars shall be completely fitted with hood, wind shield, running boards, lamps, etc., as for winter touring. In the majority of cases this regulation has been strictly adhered to. A four-cylinder Corre-La Licorne, indeed, with an engine only measuring 3.1 by 4.3 inches bore and stroke, has a closed four-passenger inside-steering body of a nature that is not usually classed with voiturettes. In several cases the letter of the law rather than its spirit has been adhered to, the wind shields being mere apologies for this article. Most, however, are fairly well fitted, though passengers' comfort has not been so well considered on the open touring car as by the English neighbors. The sides of the bodies are too low, side doors are not used, and there is a lack of adequate protection.

Mechanically there is not a great deal of variety in the competing vehicles. Large car lines are followed in the majority of cases for both external and internal features. The four-cylinder motors are for the most part in a single casting, the bore varying from 2½ in. to the maximum of 3.1 in. A long stroke is generally favored. High-tension magneto, without batteries as a stand-by, is to be found on every car in the competition. There are two cases of friction transmission, in one of which the final drive is by single chain and in the other by cardan shaft. In price the voiturettes vary from $850 to $1,200 complete.

The first two days of the trial resulted in six small cars receiving penalization. In each case the defects were minor ones, which did not prevent the cars reaching control on time. Georges Sizaire broke a spring clip; the radiator fan belt jumped its pulley on a Barré car, one Doriot-Flandrin had to tighten up a nut on the intake pipe, and another of the same make had a leaky radiator; a Turicum had to tighten up nuts on its friction plate, and the driver of a Fouillaron stayed outside the garage, filling tanks and looking over his car, until his time had passed.

AMERICA'S STOCK CAR SUGGESTIONS NOT ADOPTED

PARIS, Dec. 15—America's suggestions for stock car races were not adopted at the International Conference of Recognized Automobile Clubs. William S. Hogan received the proposals from the Automobile Club of America too late to give the necessary three weeks' notice, with the result that the matter was introduced to the meeting, but could not be discussed.

To judge from expressions of opinion gathered from the European manufacturers, the American method has little likelihood of finding favor here. Purely stock-car races never have been held in any country of Europe, speed events here being an opportunity of trying out new ideas and not of testing the standard product. Further, Europe is opposed to a piston displacement rule. Such

Turicum Four-Cylinder with Single Chain Drive

Four-Passenger Corre-La Licorne—Inside Steering Body good results have been obtained by classifying cars according to cylinder bore only, leaving manufacturers to adopt as long a stroke as possible, that it would be impossible to convert the European to a rule tending to development of short-stroke engines.

The most important work of the conference was in connection with an international triptyque. The Touring Club of Italy had proposed through its spokesman, the Automobile Club of the same country, that an international triptyque should take the place of the numerous national documents now in use. The matter has been before the road conference and the recent government conference, and there met with approval. The recognized automobile clubs, in order to help the matter forward to a practical issue, decided that each club should study the matter and present a detailed scheme for the realization of an international triptyque at the February 1 gathering of the conference. At the same time they should use their influence with their respective governments toward the adoption of a scheme having for its object the creation of an international automobile passport. There is no real opposition to the Italian scheme, but there are plenty of objections on the part of officialdom against doing things in a way that is not in accordance with their routine. As the scheme would provide an open door into every country in Europe merely on the accomplishment of a single formality, it is one that is worth working for. America's interest in it is real, for she provides a large proportion of the automobilists who travel annually over the highways of the Old World.

John Bull has reason to be satisfied with the results of the meeting, for it was decided that the automatic electric timing apparatus in which he is interested shall be given official recognition, and this or a similar type of instrument made compulsory for all races, either on road or track, of less than five kilometres distance. Colonel Holden, a member of the Royal Automobile Club of Great Britain, invented a timing machine which automatically recorded the passage of a car, and did it so well that the passage of the front and rear wheels was separately recorded at speeds of 80 miles an hour. The machine was proposed for compulsory adoption, but not immediately accepted. Now it has been decided that this method of timing shall be employed wherever it is desired that the records shall have official recognition. In order not to give the English colonel a monopoly, the conference declared that any type of automatic machine could be employed provided it was capable of recording one-fifth of a second.

The relations between the National Automobile and the National Aero clubs is a matter now troubling Europe, and have been placed in the hands of a special committee.

Gregoire Voiturette Leaving Garage to Compete in the French Reliability Trials

NINE VEHICLES SUCCEED IN MILITARY TRIALS

Paris, Dec. 15—Intimation has been given by the Minister of War that nine different types of automobiles proved satisfactory in the recent commercial and military trials held by the Automobile Club of France, and have met with the approval of the military jury. As soon as the necessary funds have been voted by Parliament, and this will be done within a few weeks, these nine types can be offered to private users with the advantage of a subsidy on condition that their owners guarantee to present them for annual inspection and to place them in the hands of the army in case of mobilization. The subsidies amount to $600 per vehicle for the first year and $200 for each of the three succeeding years. All that the army requires is that the subsidized vehicles shall be similar in every respect to those presented in the competition. This will give France a fleet of commercial automobiles ready for army purposes at a moment's call, and always kept in the best of condition, the annual inspection and the fact that they are employed for ordinary commercial purposes assuring this.

The vehicles selected are two four-cylinder Aries trucks carrying three-ton loads; two four-cylinder Aries carrying four-ton loads; a 15-horsepower three-ton two-cylinder Delahaye; two four-cylinder Delahaye trucks, each taking four-ton loads; two Berliet, two two-cylinder Cohendet, two De Dion, two Saurer, and two Vinot-Duguingand.

STRIKE OF HARTFORD TIREMAKERS

Hartford, Conn., Dec. 21—As a result of a wage cut, about 100 tiremakers at the Hartford Rubber Works Company went on strike this morning. The strike proper began Monday morning, when a number of the tire builders failed to show up for work. The factory has been running twenty-four hours a day for some time, so that there are two shifts of workmen. Those in to-day's demonstration were of the day force. Rumors of advanced prices in crude rubber have been spread for some time, and it was said might be used as a reason for a general wage reduction. No definite cause has been stated as yet. The local tiremakers are paid by the day—earning from $1.75 to $3—and the cut, which ranges from 15 to 33⅓ per cent., averages 24 per cent. for the whole body. The tire builders have no union, and this phase does not enter into the question. The strikers congregated at the works this morning and induced others to join them, and then formed a demonstration and marched to a nearby hall for a prolonged meeting.

Justen D. Anderson, president of the Hartford Rubber Works Company, when asked as to the strike, said that he had nothing to say.

Aitken, Driving the National, Broke All American Records for Stock Cars

SPEEDWAY RECORDS DESPITE ZERO WEATHER

INDIANAPOLIS, Dec. 18—Considering the weather conditions, the speed trials on the Indianapolis Motor Speedway yesterday and to-day could be termed eminently successful. The events, which were the first on the course since the track has been paved with brick, merely gave an indication of what may be expected when the weather is more favorable.

The speedway management, in fact, is fairly well satisfied with the results. With the thermometer hovering near the zero mark, causing frequent carbureter trouble, and with the drivers suffering from the intense cold, some remarkable time was made. The most notable feat was that of Strang in his 120-horsepower Fiat covering five miles in 3:17.70, establishing a new record, the former record for thed istance being 4:11.3, held by Oldfield and established on the local course last August.

Inclemency of weather detracted somewhat from the mass of interested spectators, yet the total attendance was quite satisfactory, being of the substantial sort, to whom a little detail like zero weather would have but small influence in the face of the expected performance, nor can it be claimed that they were disappointed. Then, there were opening speeches, congratulatory opportunities, the meeting of workers in the vineyard, they who stood shoulder to shoulder in the good fight.

Ceremonial Placing of the Last Brick

Just prior to the first trials yesterday afternoon, the ceremony of placing the last brick in the course was held in front of the judge's stand, at the finish line. This brick is of coin silver, plated with gold and weighs about fifty-two pounds. It was placed in position by Governor Thomas R. Marshall, assisted by his private secretary, Mark Thistlethwaite.

Stillman, Warmly Hooded, at the Wheel of the Marmon

Newell Motsinger, driving a 20-horsepower Empire, was the first to start after a record on the new brick course. He entered in the class for cars having a piston displacement of 160 cubic inches and under, and was the only entrant. Summary of the afternoon:

Class 5—160 inches and under piston displacement—Empire No. 10 (driven by Newell Motsinger, only entrant), one-fourth mile in 18.73 seconds, one-half mile in 38.18 seconds, one kilometer in 48.31 seconds, one mile in 1 minute 20.46 seconds.

Class 4—161 to 230 cubic inches piston displacement—Cole No. 9 (driven by Endicott, only starter), one-fourth mile in 15.69 seconds, one-half mile in 31.70 seconds, one kilometer in 39.88 seconds, one mile in 1 minute 05.97 seconds.

Class 2—301 to 450 cubic inches piston displacement—National No. 5 (Aitken, driver), one-fourth mile in 11.60 seconds, one-half mile in 23.20 seconds, one kilometer in 30.20 seconds, one mile in 49.20 seconds.

National No. 4 (Kincade, driver)—One-fourth mile in 11.80 seconds, one-half mile in 22.60 seconds, one kilometer in 30.20 seconds, one mile in 50 seconds.

Class 1—451 to 600 cubic inches piston displacement—Packard No. 12 (O'Donnell, driver, only starter)—One-half mile in 27.80 seconds, one mile in 58.60 seconds.

Strang's Five Miles Fastest on Saturday

The sun to-day was a bit warmer, but nevertheless the wind made driving decidedly unpleasant. Nothing longer than five miles was attempted, in which, however, a new record was established for one mile on the track, and also a new record for five miles. These trials, briefly summarized, were as follows:

Car and Driver	1-4	1-2	Kil.	Mile
Christie (Christie	:09.04	:18.11		:50.10
Christie (Christie)	:08.92	:18.23	:24.50	:42.58
Christie (Christie)	:08.37	:17.53	:22.86	:43.03
Christie (Christie)	:08.70	:18.08	:23.45	:43.77
Fiat (Strang)	:09.07	:18.62	:23.65	:39.21
Fiat (Strang)	:08.92	:18.39	:23.36	:39.36
Empire. 20 (Motsinger)				1:17.03

Strang's time for the five miles—3:17.70—was easily the sensation of the meet. He had a flying start before starting on the five miles. This mile flying start was as follows: One-fourth mile, :08.05; one-half mile, :17.82; one kilometer, :22.70, and the mile, :40.02. His first mile of the five miles is given above, being in :39.96. His time for the first lap of two and one-half miles was 1:38.80. The first mile of the second lap was made in :39.66, the quarter of this mile being :09.02; the half, :18.62, and the kilometer, :23.52.

The drivers suffered intensely from the cold. Despite the fact that they wore heavy gloves and had their faces protected by woolen bandages they were almost frozen during the trials. When they stopped their cars they could scarcely move their bodies and frequently had to be lifted out. Once after Strang had completed a trial he found his face was almost frozen and washed it in the icy water of the stream that runs nearby.

C. H. Werner, of the Werner Instrument Company, Beloit, Wis., had charge of the timing. The same special Werner timing device that gave such excellent satisfaction at the previous local meet, as well as at the one at Atlanta, was used. Only once was trouble encountered, and that was when the one kilometer wire was damaged.

Officials of the meet were: Honorary referee, Gov. Thomas R. Marshall; referee, Frank H. Martin, Chicago; starter, Fred J. Wagner, New York City; announcer, E. A. Moross; paddock manager, O. G. Temme, Chicago; board of judges, C. G. Sinsbaugh, Chicago, Robert H. Kramer, Mudlavia, Charles Root, Chicago, Thos. Hay, Chicago; board of timers, F. W. Kohl, Cleveland, Frank Remy, Anderson; scorer, John S. Cox, Terre Haute; timing director, C. H. Werner; representative of racing board of A. A. A., C. W. Sedwick; clerk of course, W. H. Wellman; director of contests, E. A. Moross, Indianapolis.

The trials were with the sanction of the A. A. A. Not a single accident marred the two days' events, and from indications, as it would seem, this track will have a vast influence on the future of racing, partly because of the new records, which were established under adverse conditions, and again, since safety is established under speed conditions. That the banking angle, as

Strang at Wheel of Record-Breaking 200-Horsepower Fiat

it obtains at Indianapolis, is a wise one, seems to be proven, and those who may have had to struggle with this important matter will fully appreciate how apparently simple it looks to fix the angle of banking, and yet, in an actual trial the simple fixing fails to deliver satisfaction.

Despite the exactness with which the present angle of banking seems to satisfy the conditions of racing, which angle, it will be remembered, is maximum at 36° 40", other means of safeguarding the course are available, as for illustration, the buttresses are reinforced, all around the curves, as shown in the title illustration, so that they project up, and above, some 33 inches. These reinforcements are of concrete, with a 9-inch thickness of wall at the top, tapering off to give strength and stability. Under the new conditions safety is further assured. due to a 15-foot sweep on each side of the brickway, the same having been leveled off after having been filled in with a depth of filling, the same having the characteristic of rolling down firm, and the further property of remaining so, even under conditions of protracted inclement weather. This wide sweep on each side of the track assures that a disabled car going at top speed will have a wide field in which motion may be arrested, thus affording the driver and his mechanician reasonable opportunity.

The management is to be congratulated for its persistence, having expended a vast sum of money in brick-paving the track, after it was found that no other class of pavement could be regarded as safe, considering the possible speeds of modern racing automobiles. That all records will be broken, under fair conditions of weather, is now assured.

Governor Marshall, of Indiana, Placing the Golden Paver Which Completed the Track Into Its Position

Yielding Wheel with Steel Side Plates Removed

ANOTHER FRENCH SPRING TRUCK WHEEL

PARIS, Dec. 8—France, always active in the spring wheel line, has produced another. This one, shown in the two accompanying pictures, is not strictly a spring wheel, in that no springs are used, at least springs do not form the major part of the design. They do, however, belong in the same class, for the idea is to do away with pneumatic tires. As the illustrations show, there is an outer tread of hard rubber, within which a layer of soft rubber forms a yielding felloe. The latter is made in many small sections, with holes through them, through which holes the bolts to hold on the steel side plates pass. Below this, in turn, there is another felloe of wood, attached to the ends of the spokes in the usual manner. But between the two is a sort of air bag, which may be inflated somewhat, increasing the yielding effect of the whole wheel, which is the desired object.

Same Spring Wheel Complete Ready for Use

OLYMPIA SETS NEW BODY FASHIONS

LONDON, Dec. 7—As was stated in the last report of the mechanical features of Olympia, chassis fashions have not altered greatly, except in details. The same thing, however, cannot be said about the carriage work, for on all sides there is evidence of great improvement. The reason for this is not far to seek. In previous years the attention of both manufacturer and user has been centered on the "machinery" to such an extent that there has been comparatively little interest available for the body builders' department; but now the chassis is becoming less in need of continual improvement, and, in consequence, the importance of the carriage portion of the car has grown considerably.

In open cars, the striking features are general adoption of high side doors for the front seats, and the prevalence of the flush-side, or torpedo style of body. These side doors make such a distinct improvement, both in comfort and in appearance, that it seems surprising that all bodies were not thus fitted long ago. To afford a maximum of comfort, the doors must be as high as the arm rests of the front seats, and the result is that with a very short body or a carelessly designed two-seater, the effect may not be pleasant to the eye. With this exception, however, the front doors may be taken to be a very material improvement.

The flush-sided body is immensely popular, and, as might be expected, there is much rivalry between makers as to which was the originator of the type. Captain Masui, of the Germain Company and the Hewer Body Company, Coventry, seem between them to have been the responsible parties, but it is interesting to note, as showing the quick development of the type, that no example can be traced previously to the summer of 1908.

There are many varieties to be seen—some of which bear but little resemblance to the original type. To be most effective the body must be joined on to the bonnet by a sloping line, so that the top of the car may present an unbroken outline from the radiator to the hood at the rear. Hence, it will be recognized that this body is seen to best effect when the front of the car is on Renault lines, or, if otherwise, when the bonnet and radiator are higher than the average. The former case is well exemplified by the Arrol-Johnston, the latter by the Hobson car

A special feature in favor of the flush-sided body is that it can be made specially light, for the framework can consist of a properly braced wooden skeleton with sheet metal panelling In passing it may be stated that aluminum is becoming less popular as a material for panelling, its place being taken by sheet steel.

There also seems to be, this year, an increase in the proportion of covered cars, not only in the case of town carriages, but in touring vehicles also. Popular opinion favors the convertible type, such as the landaulet or the cabriolet rather than the limousine. The cabriolet, in particular, is becoming fashionable. somewhat in the same way as the torpedo in the open body section. A year ago it was the exception to meet with a body of the cabriolet type, but at the present exhibitions there are a dozen staged by various makers. It is unquestionably more expensive to make than either the limousine or the laudaulet, but its great advantage as a completely convertible carriage is likely to make it come into general favor with users of high priced cars. More than this, it fills a special field midway between the enclosed and open bodies, in large establishments, having a distinct usefulness for afternoon strictly of its own.

Other noticeable advances are the general use of electric lighting for cars of every type, and also the provision, in many cases, of a black leather hood in place of the cape cart hood of canvas almost invariably used before.

Luggage carriers at the rear of the covered cars are now usually fitted, instead of the grid on top of the body. When a rear petrol tank is fitted the filling orifice is arranged at the side in such a way that it is accessible without removing the luggage.

Latham with a Pupil in Antoinette Two-Seated Monoplane, Which He Calls "The Taxicab"

YOUNGER FARMAN MAKES CROSS-COUNTRY RECORD

PARIS, Dec. 10—Maurice Farman, younger brother of the aviator Henry, now holds the world's record for long-distance cross-country flying. Starting from his shed at Buc, about twelve miles from Paris, he made an uninterrupted flight as far as the suburbs of Chartres, 44 miles away, in the record time of 59 minutes. His average height was 280 feet.

Maurice Farman has had his flight in view for over a month, but owing to bad weather has not been able to put it into execution earlier. After heavy storms a complete calm prevailed yesterday, the biplane was brought out, quickly prepared, and at 3 o'clock in the afternoon soared away for the city on the Beauce plain. Owing to the uneven nature of the country, Farman did not steer a perfect straight course, but at the outset flew westward, instead of southwest, in order to get directly over the main road from Versailles to Rambouillet, which lies in level country. After crossing the forest of Rambouillet, sacred to the presidents of France, the Cathedral of Chartres could be seen nearly thirty miles away. The country was level with the exception of a portion just outside Chartres, where a deep valley had to be crossed. The main road and the railway served to guide the aviator, who took up a course between the two, and was clearly visible to the occupants of the trains.

It is very probable that Farman will continue his journey as far as Bordeaux, nearly 300 miles from Paris, taking it in several stages. There is a fascination about a flight from Paris to Bordeaux, for it is over this road that the first long-distance cycle races were held and later some important automobile races.

Maurice Farman's biplane is a machine of his own design built for him at the Mallet factory. In general features it resembles the aeroplane employed by his brother Henry, though its details are distinctive, and are entirely the outcome of Maurice Farman's personal research. The motor is an eight-cylinder air-cooled Renault, with the cylinders in V. In order to obtain a slow-speed propeller without the use of special reducing gear, the camshaft is strengthened considerably and receives the propeller on its extension. The propeller is a two-bladed type built by Chauviėe, having a diameter of 8 feet 3 inches, and turning at 700 revolutions a minute. This is the first occasion on which the Renault motor has been used for an aerial flight of any importance. Farman declares himself thoroughly satisfied with his motor, but he is responsible for much of its success, by reason of the detail modifications he has made and his careful tuning-up.

Maurice Farman, the youngest of the three brothers, is a pioneer in the automobile world. Before the self-propelled vehicle came into existence he was a successful cyclist, forming a team with his brother Henry, which could never be beaten. He entered the automobile industry as soon as it sprang up, driving high-powered cars in most of the early races, generally for Panhard-Levassor. He is now at the head of the Palais d'Automobile, together with M. Neubauer, his establishment being by far the largest automobile garage in Paris. Maurice Farman was a balloonist before becoming an aeroplanist, at one time holding the French record for long-distance travel. All his aerial experiments have been carried out in the spare time obtainable from his business, this explaining the slower rate of progress compared with his brother Henry.

TWO HOURS' PRACTICE MAKES AN AVIATOR

DETROIT, Dec. 20—"Driving an aeroplane is a matter of two hours of practice," said Wilbur Wright during his visit here to attend the organization of the Aero Club of Detroit. "I can take a man up and in two hours he will know enough to run the machine. You ask why it is that men did not operate aeroplanes before. I will tell you. Men did not have the art of balance, they did not know how. That is all. We brought out the aeroplane and gave to the plane a balance which made things possible that were not possible before. I do not know that you were ever caught on a cake of ice in midstream. The ice, if so, rocked with you. When it tipped one way you naturally went across to the other side to bring it to a balance and then you went to the center to hold that balance. It is a good way that way with an aeroplane."

"But they say that you have not really shown the possibilities of the aeroplane and that you have held back in your demonstrations; in other words, that you have never shown the real possibilities of the aeroplane in flight?"

"That is not altogether true, for we have made some flights which should have shown the possibilities of the machine. However, greater things are coming than any that have been seen."

"It was too bad that you should have had trouble at New York when you might have sailed around the city." Wright answered:

"That was bad, but it happened on the ground, and had my engine have blown out a head in the air things might have been different. I am glad, rather glad, that it happened where and when it did, but I should have liked to have made that flight."

In speaking of the jump made from the bicycle to the aeroplane, escaping the automobile, Mr. Wright, whose brother smiled at the thoughts, said: "We did not altogether jump from the bicycle to the automobile. A friend of ours had an automobile in Columbus and we did a lot of work helping him to make the thing run. Then we planned on flying and our interest in the troublesome automobile vanished. Our time was given to the aeroplane and to experiments."

When the subject of Tillinghast and his reported flight from Boston to New York and back with two other men was broached to him, Mr. Wright said: "I did not read that story at all. I was called up by a New York paper with regard to it and had to tell them that. However, I do not really believe that that flight was made. It is, of course, true that lots of people are working on aeroplanes throughout the United States, and perhaps they have struck it as we did; but from Boston to New York and return with the motor going wrong in the air and being repaired without alighting, never."

Approached in regard to a location in Detroit for an aeroplane factory, both Wrights refused to talk outside of stating that they had already seen several locations.

The Wright brothers conducted a small bicycle company away back in 1893 and 1894 at Columbus, O. "It's a far flight from then until now," laughed Wilbur Wright, "for when we made bicycles to run on the ground we hardly planned to some day ride in the air, but we are doing so now. That was one great day, the days of the bicycle, but this is another, and we have just skipped over the automobile day, spending our time, while others made fortunes in automobiles, in developing the third stage, the aeroplane."

When the subject of his participating in flights during the coming year was brought up to him, Orville Wright said: "We shall undoubtedly delegate most of that to others and attend to business. The demands upon us for business will compel us to retire from the field of contest. However, there is altogether too much enjoyment in a real flight to ever keep us out of the air. Our flights will be made in private, however. It is not really our intention to take part in public contests."

Both of the Messrs. Wright laughed over the efforts of the photographers to get into touch with them while they were at work at Kittyhawk, N. C., experimenting with gliders. "There was one photographer down there (it was Jimmy Hare of Collier's) who laid low day after day for us and got something. Others have followed the same tactics since. We are now rather accustomed to being photographed and do not mind it so much. But some men with cameras are an awful nuisance."

AUSTRIA'S FIRST STEPS IN AVIATION

Berlin, Dec. 11—Austria's first home-made aeroplane has stood its primary test well on the aviation ground near Vienna, where it achieved a flight of nearly five kilometers, guided by the constructor, Etrich.

Berlin's example in opening an aero section in the Post museum might well be copied by other large cities, for it is a decided step in the right direction. The postal authorities have placed an order for models of four aeroplanes and two airships with a local firm, and permission has been requested from the war office to carry out a replica of the Gross as well as the Zeppelin and Parseval already ordered. The aeroplanes are copies of the Wright, Blériot, Latham and Grade flyers, and will be exact in every detail, even the same kind of wood being used as in the originals. All the aeroplanes are to be one meter in length and one-and-a-half over all, while the Zeppelin is a seven-meter copy of Zeppelin III, and the Parseval on the same scale proportionate to the original. Each part is to be numbered and full information given on a table over each apparatus.

PROVISIONAL CALENDAR OF 1910 EVENTS

Paris, Dec. 16.—An attempt is being made by the aeronautical associations of Europe to draw up a calendar of events for 1910 in order to prevent clashing. The first list has been drawn up by the Aero Club of France, and will be submitted to the Mixed Commission in order to be modified by them if any clashing is likely to take place. The following is the provisional list:

February 6 to 13, Heliopolis meet, Egypt. Prizes, $42,400.
April 1 and 2, Biarritz meet. Prizes, $40,000.
April 3 to 10, Cannes meet. Prizes, $1,600.
April 15 to 25, Nice meet. Prizes, $48,000.
May 7 to 9, Croix d'Hins, Bordeaux, meet. Prizes, $8,000.
May 14 to 22, Lyons meet. Prizes, $30,000.
June 5 to 12, Vichy meet. Prizes, $6,000.
July 3 to 10, Elimination race for Gordon Bennett contest.
Sept. 4 to 11, Croix d'Hins, Bordeaux, meet. Prizes, $40,000.
Sept. 23 to 30, flight from Havre to Trouville and Deauville, across mouth of River Seine. Prizes, $40,000.

In addition to these events, with a total prize list of $256,000, there are several others not yet included on the programme, among them being the second Rheims meeting and the Automobile Club of France's flight from Paris to Brussels. Prizes which are eligible for competition any time during the year are not included in the programme.

SEEK PERMIT FOR LOS ANGELES MEET

Action on the application of the Aero Club of Los Angeles for a license for an aeronautic meet in that city will be taken at a meeting of the board of directors of the Aero Club of America December 22. The proposed meet is supported by both the Los Angeles Club and the Merchants' Society, and as the principal desideratum in the granting of a license is the financial responsibility of the promoters, it is highly probable that Los Angeles will get the meet.

The meeting is intended to begin January 3 and last ten days, and $80,000 prize money has been raised. Louis Paulhan, the French aviator, has been engaged, and sailed from France Tuesday. Glenn Curtiss will also appear, and it is said that there may be no less than six Curtiss machines present. Their pilots, besides Mr. Curtiss, will be C. F. Willard, C. K. Hamilton, C. B. Harmon, A. P. Warner and M. de Riemsdyk, a Netherlandish aviator who has been flying at Hammondsport, N. Y., recently.

ALEXANDER WINTON BUYS AN ANTOINETTE

Cleveland, Dec. 17—During his recent European trip Alexander Winton, the president of the Winton Motor Carriage Company, ordered a 50-horsepower Antoinette monoplane, which is to be delivered in this country next May. This machine is of the type with which Latham holds the present world's record for altitude. The standard Antoinette machine measures 36 feet across the wings and 34 feet from propeller to rudder. It has 280 square feet of supporting surface and weighs 1190 pounds

ROCHESTER, N. Y., AERO CLUB FORMED

Rochester, N. Y., Dec. 17—The Aero Club of Rochester was formally organized here last night with a membership of sixty-five. President Taft, Governor Hughes and the Mayor of Rochester are honorary members, ex-officio. Incorporation papers have been prepared, and will be filed at once. The new club expects to hold a big aviation meet next Fall.

WILL HAVE AERONAUTIC MOVING PICTURES

Baltimore, Dec. 19—Moving picture proprietors have become interested in the movement of the Aero Club of Baltimore to have the next international meet on a site somewhere between Baltimore and Washington. These gentlemen got together and made a subscription of $1400 toward the $50,000 fund.

ROADS BUILDING NEWS FROM ALL OVER THE COUNTRY

MASSACHUSETTS' LOSS IS CALIFORNIA'S GAIN

BOSTON, Dec. 20—The cause of good roads in Massachusetts loses one of its ablest advocates in the resignation, announced to-day of Austin B. Fletcher, secretary of the Massachusetts Highway Commission since its organization sixteen years ago. But Massachusetts' loss is to be another State's gain, for Mr. Fletcher is leaving here to take charge of road building on a very large scale in Southern California. He will have full charge of the construction of 400 miles of high-class roads, which is half as much mileage as there is in this State, and to begin the work he has available an appropriation of $1,500,000. Good roads have been advocated in Southern California for some time.

After the appropriation was made, it was determined to obtain the best possible authority to have charge of the work. Mr. Fletcher has a national reputation as an authority on road construction, and he was offered the position together with a most attractive salary. A few weeks ago, he went to California and after investigating the conditions, decided to accept the offer. He will leave Boston about the first of the year.

When the Massachusetts Highway Commission was organized sixteen years ago, Mr. Fletcher became its secretary. The Commission was then a comparatively small affair and was engaged in the construction of samples of improved road for the education of local communities. This work gradually broadened until the Commission has now under its jurisdiction about 800 miles of highway stretching from Massachusetts Bay to the Berkshires, and from the southern to the northern boundaries.

In all this road work, Mr. Fletcher has been a most valuable assistant of the commissioners. A year ago last summer he was one of the delegate from this country to the International Road Congress in Paris. He has often spoken at road conventions in the United States and has written much on the general subject of good roads.

In addition to his connection with the road department of the commission Mr. Fletcher has been prominent in the development of the administration of the automobile law, a duty which has been in charge of the commission since the passage of the first automobile law in 1903. He has been largely in charge of the systems of registration of cars and licensing of operators devised to meet the different requirements imposed from time to time as the law has been changed.

It was largely under his direction that the most recent plan for registering automobiles on a horsepower basis was arranged. He also had direction of the two road censuses taken this summer, which were the most comprehensive ever undertaken in the United States. Mr. Fletcher has also had an important part in the other department of the Highway Commission"s activity, which is the supervision of the telephone and telegraph companies operating in Massachusetts.

OHIO OBJECTS TO FEES BASED ON HORSEPOWER

COLUMBUS, O., Dec. 20—The announcement that Chairman Ritter of the House of Representatives Finance Committee will present a bill in the next session of the General Assembly providing for an incrase in the registration fees for automobiles, based on their horsepower, has aroused a storm of opposition. Automobile owners believe that the present fees are sufficient.

One of the chief arguments against the Ritter bill is the likelihood of its being declared unconstitutional, as the Ohio constitution makes no provision for State licensing. The present fee is classed as a fee for registration only, but it is argued that as it costs no more to register a 60-horsepower car than an electric runabout, a sliding-scale fee would be distinctly a license.

LIVE PLANS FOR LANCASTER COUNTY

LANCASTER, PA., Dec. 20—As the farmer and the automobilists are steadily getting closer together in road matters, the actions of every progressive automobilist and automobile club are of great interest to our readers. One of the most efficient organized bodies of workers for highway improvements of all the automobile clubs in the United States is the club of the historic old town of Lancaster, Pa. The efforts of this club during the past several years have brought much benefit to the farmers scattered throughout entire Lancaster county. Roads have been improved where previously lethargic road officials permitted them to be neglected. Signboards over Lancaster county have been erected, and the law enforced compelling supervisors to remove loose stones from the roadways. Stubborn and inefficient turnpike companies have been brought to terms and been made to improve the roads over which they exacted toll tribute, and generally better roads have been brought about by the activities of the club.

As the club's good-roads efforts during the past year have been very conspicuous, the management is able to announce that Supervisor John F. Weaver, one of the most practical roadmakers in the country, has accepted an invitation for a practical talk on "Road Making From the Farmers' Standpoint." West Lampeter township, from which he hails, was the first township to accept the club's offer of a King drag last Spring, and was the first township to officially inaugurate this system of dirt road maintenance.

Another guest will be Joseph H. Weeks, president of the Delaware County Automobile Club, who will talk on the newly formed Pennsylvania Good Roads Association, and its efforts to get the Lancaster turnpike repaired between the Gap and Coatesville. A number of Chester county automobile men, Harrisburg Motor Club men and some Philadelphia Automobile Club men have signified their intention of being present.

KENTUCKY MOTORISTS INTERESTED IN INDIANA ROADS

LOUISVILLE, KY., Dec. 20—Constitutional obstacles to good roads in Kentucky having been removed, that State, at least the motorists of that State, are greatly interested in the efforts for good roads being made in Southern Indiana. The merchants of New Albany, together with the farmers of Floyd County, are taking steps toward the betterment of the roads in that county.

Roads through this section of the Hoosier State lead to the Kentucky and Indiana bridge over which motorists travel to enter Kentucky. Floyd County particularly is far behind other counties in Indiana. The only toll roads in the State now remaining are in this county, all the others being free.

There was a movement on foot some time ago to have the county take over the Paoli and Corydon turnpikes and make them free, but as there is a prospect of the pikes being sold to traction companies for the building of electric lines between New Albany and French Lick, and between New Albany and Corydon, the scheme has been temporarily abandoned.

It has developed that some of the farmers in Floyd and other counties are depending upon a proposed act of Congress to secure good roads, and as this is a visionary scheme, the farmers are urging the County Commissioners to pay more attention to road building and repairs.

An election will be held on December 18 for Road Supervisors in New Albany and other townships in Floyd County and in the Third District. If capable men are selected to fill these positions it is expected that the good-roads movement in Southern Indiana will receive an impetus worthy of the approval of the automobilists.

BOSTON, Dec. 20—On January 1 the new Massachusetts automobile law goes into effect. The law was passed last June, and the first of July four sections took effect. These relate to the equipment of cars, brakes, lights, etc., rules of the road, speed limits, and special speed regulations. On the first of this month certain other sections permitting the Massachusetts Highway Commission that is charged with the administration of the law to prepare blanks and forms for the registration of cars and the reissue of licenses became effective, and under these sections the commission has been issuing registration certificates on a sliding horsepower scale from $5 to $25 and new licenses to be used after the first of January.

Ten Days for Non-Residents—The main body of the law, however, goes into effect on the first of the year, and a summary of the more important changes may be useful. The rights and privileges of non-residents have been somewhat enlarged by the new law. Under it a non-resident or his chauffeur may operate in Massachusetts for ten days instead of seven without securing a state registration or license, and if a non-resident desires to operate his car here only during the months of July, August and September he may have it registered at half rates. As heretofore a non-resident convicted of violating the automobile law must secure a state certificate and license. A new distinction is made under the law. Persons previously designated as private operators are under the new statute operators, and chauffeurs include everybody who operates for hire, but manufacturers, agents, dealers and salesmen.

Half-Rate Registration—Under the sections relating to registration provision is made for half-rate registration after the first of October in any year and for rebates or increased payment when registering a new car of lesser or greater horsepower than that previously registered. Motor cycles will not have to carry numbers as in the past, but will have small seals affixed to the machines and the registration of a motor cycle carries with it the right to operate without payment of an additional fee. The number of registration plates allowed manufacturers and dealers for their fee of $25 is limited to five with an additional fee of $5 for each additional set of plates. A new requirement relating to number plates is that they must be horizontal and not less than 8 or more than 36 inches from the ground, and the rear plate must be illuminated at night so that it is visible at a distance of 60 feet.

Age Limit Is Sixteen Years—There will be no more driving of motor cars by children for the law sets a limit of 16 years on applicants for operators' licenses and 18 years on applicants for chauffeur's licenses, and a licensed operator accompanied by an unlicensed person at the wheel is made liable for any violation of the law by the person driving.

One of the most striking changes in the law is the cancellation of all the licenses that have been issued in the past six years to private operators and the placing of the license matter upon the same annual basis as registration certificates. There have been issued since 1903 something like 35,000 operator's licenses and until now they have been perpetual. Their renewal costs fifty cents each.

Penalties More Drastic—Material alterations are made in the penalties to be imposed for infraction of the new law, and the penalties are more drastic than formerly. Minimum penalties of $10 for a first offense, $25 for a second and $50 for a third are established, the maximum penalties remaining at $25, $50 and $100. The maximum fine for reckless driving, operating while under the influence of intoxicating liquors or so that the lives or safety of the public might be endangered, operating for the purpose of making a record or on a bet, wager or in a race, going away without stopping after an accident and using a motor vehicle without authority, is increased from $100 to $200, and for a second conviction for any of these offenses the penalty is imprisonment from one to two years. Any officer authorized to make arrests may arrest without warrant and keep in custody for not more than 24 hours, unless Sunday intervenes, any person operating without a license or who violates the automobile law. For violations of the speed rules the offender is permitted to put up $100 cash in lieu of a bail bond. The municipal police are required to report to the Highway Commission all accidents which cause, or seem likely to result in death.

Scale of Fees—The new scale of registration and license fees is as follows: Motor cycles, including right to operate, $2; commercial motor vehicles, $5; automobiles less than 20 h. p., $5; 20 h.p. and less than 30 h.p., $10; 30 h.p. and less than 40 h.p., $15; 40 h.p. and less than 50 h.p., $20; 50 h.p. and above, $25; manufacturers and dealers $25 for five cars and $5 for each additional car; manufacturers and dealers in motor cycles for ten machines, $10; non-resident registration in July, August and September and all registrations after October 1st, half rates; substitution of registration of an automobile for that of a vehicle previously registered, $2, and payment for increased horsepower: substitution of registration of a motor cycle for that of a motor cycle previously registered, $1; original operator's or chauffeur's license, $2; renewal, 50 cents; examination of operators and chauffeurs, $2; additional copies of certificate of registration or license, 50 cents; additional number plates, 75 cents.

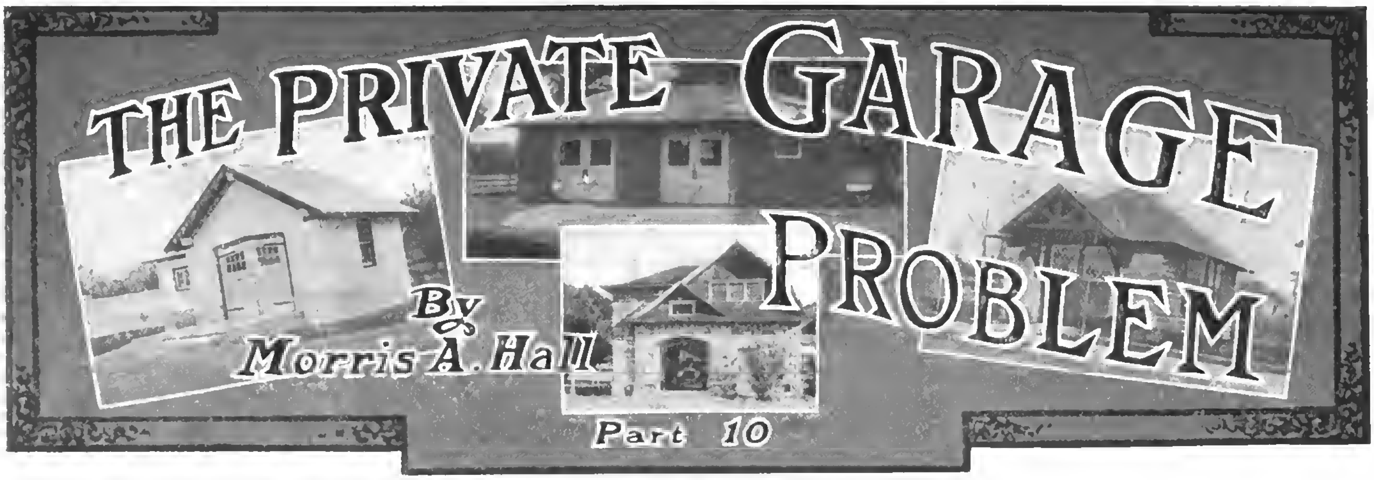
Under the new law not only the fees received for registration and licensing, but all fines imposed by the courts for infraction of the automobile law will go to the State treasury and must be used for the maintenance of the state highways.

One absolutely certain result of this diversion of the money received will be to improve the roads with the fees paid by their users for that specific purpose, which is but logical and right.

LEGAL BREVITIES OF INTEREST TO AUTOISTS

In Washington, D. C., a new police regulation prohibiting owners of automobiles from allowing their machines to give out smoke and fumes in the streets has been drafted, because Judge Mullowny ruled that the old regulation was invalid since it discriminated in favor of certain streets. The matter arose over the arrest of a local automobilist charged with violating the smoke regulation. His counsel argued that the regulation was discriminatory and unlawful in that it applied to only certain of the downtown streets. The case was dismissed and a new regulation covering the emission of smoke and fumes from automobiles throughout the city has been drafted.

A wealthy Camden, N. J., builder, Patrick J. Farley, **was** severely punished last week for repeatedly violating that section of the New Jersey automobile law which prohibits the licensing of drivers under 16 years of age. To save the hire of a chauffeur, it is said, Farley allowed his 14-year-old son, Clair, to drive his big six-cylinder car even after numerous warnings, and last Thursday Motor Vehicle Commissioner Smith not only revoked his 1909 registration and license, but gave orders that no credentials be issued to him for 1910.



A Group of Small and Medium-Sized Garages, of Various Forms of Construction, Which Show Intelligent Design

EQUIPMENT plays a very important part in the small garage; first, because it influences the size and planning of the whole building, and second, because of its influence upon the cost of upkeep. Thus, paradoxical as it may sound, if he could afford a complete equipment so as to do all of his own repairing and adjusting, every man, no matter how poor, could afford to own and run an automobile. That is to say, if he were in a position to keep repair and upkeep charges down to an absolute minimum, the expense of running would be trifling. The fuel economy of the modern small car has by thought and improvement in design been reduced to a very small quantity, and it is no trick at all now-a-days to make and average 25 miles per gallon of gasoline.

All this brings out the relative and far-reaching importance of proper equipment, which will, for this reason, be the subject of this week's paper. Many small devices which are useful, to say nothing about economical, will be described and illustrated. Some of these small helps are such that any handy man can make them.

Great Importance of a Turntable—Many a man provides in his design space for maneuvering the car around, either inside or outside, or both, when the same result might be attained in a much simpler manner, and doubtless with a far less expense, by the use of a turntable. This may be as small as the length of the wheelbase, plus a very small margin to allow for the width of the car and some clearance. Actually the smallest diameter which may be used is the hypothenuse of a triangle, of which the tread forms one side and the wheelbase the other. When this has been figured for any given car, a small amount should be added as above for clearance. Figured out on this basis, a 10-ft. turntable will give nearly 6-in. clearance for a 100-in. wheelbase car.

With the turntable, the car need not be maneuvered at all, it can be driven right in onto the centrally located and circular turntable, which is then revolved to bring the car to the position desired, or to point it in the direction in which it is desired to leave. Of course, it is not a substitute for a pit, but having a turntable in the center of the floor does not cut into the available floor space as does a pit, so that instead of a subtracting factor it becomes an additive quantity, in that floor space is saved or gained instead of lost.

To the little fellow, building his first garage, and that, too, a very small one, the item of size is a very important one, and any hint that will help to reduce this size, and of course with it the total cost, is eagerly grasped. To this man the turntable is a godsend, for it may take up the whole central part of the floor, the expense of which may then be practically neglected, since it is included in the cost of the turntable. While the latter are not given away by any means, the price, considering that the whole center of the floor is included, is not so very high.

In the case of the larger garage, too, the saving effected is such a large one as to be worth considering, say for a two-car garage. In this case, the extra space for maneuvering the two cars may amount to as much as 50 per cent. additional area, that is the equivalent of the space taken up by one car. Bearing in mind that this additive quantity is not added alone to the floor, but to all four sides, the ceiling if any, the four sides of the roof, to the foundations, to the fireproofing, to the painting, to the depreciation and upkeep, and some idea of the importance of proportioning the ground area closely to that actually required by the cars owned may be obtained.

For the very large garage, on the other hand, the garage for three or more cars, the expense is of less weight, but the turntable will be found in these buildings for the convenience of shifting cars around. From all of which it would appear as if it was somewhat of a necessity, a place for it having been found in the small, the medium-sized and the very large garage.

Elsewhere on this page will be found a drawing showing a cross-section through one of the turntables now on the market, this being constructed from structural iron, in such a manner as to possess not alone strength, but a minimum of weight. While the size shown is 12 ft. in diameter, smaller and larger sizes are made to suit any sized car. However, the car which would call for a larger size than this, would be an unusual one, since this will take a car with 132-in. wheel-

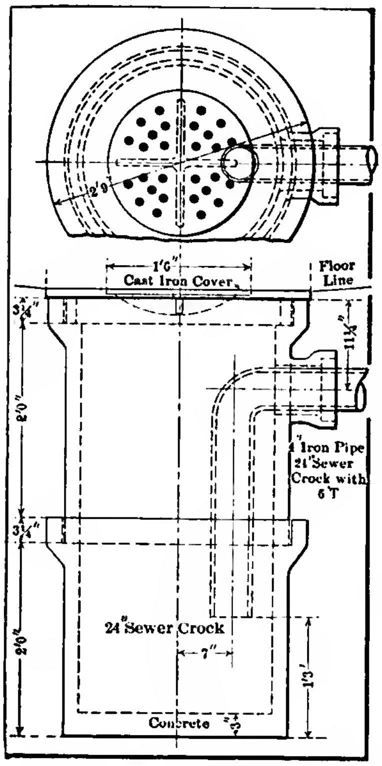
Two-Compartment Oil Trap Built of Concrete

base. Of the cars listed last year at show time in THE AUTOMOBILE special show numbers, numbering about 1,000 in all, just eight exceeded this figure.

In detail, a box girder forms the central part or hub and carries the central pivot upon which it is supported in part and upon which it turns. From this central member eight structural iron arms radiate to the rim, which is a heavy section channel open side out, bent to the desired radius. The lower surface of the latter runs or rolls upon a series of eight rollers set into the foundations and equidistantly spaced. Across the middle are set two stiffeners, which aid in keeping the shape and level of the whole structure when supporting heavy loads. The top or floor surface is of light sheet steel riveted to the members below, while the lower side is left open.

To install one of these in a garage, all that is necessary is the central foundation of cement and the circular ring, built up to such a level as to bring the rollers into correct contact with the underside of the rim channel.

Proper Drains of Great Importance—In the construction period one thing that must be taken seriously is the matter of drainage. It is practically impossible to avoid spilling both oil and gasoline on the floor. With the continuous washing going on the water will wash both into the drain and thence into the sewer. Neither one will mix with the water, but will float upon its surface ready and willing, as it were to ignite at the first sign of heat or flame. Such heat or flame, setting fire to this oil and gasoline in the drain pipes or sewers, may do incalculable damage, not necessarily to the garage from which it came. For this latter reason, and as a matter of common fairness, every owner should see to it that his drains do not carry off any fuel or oil.

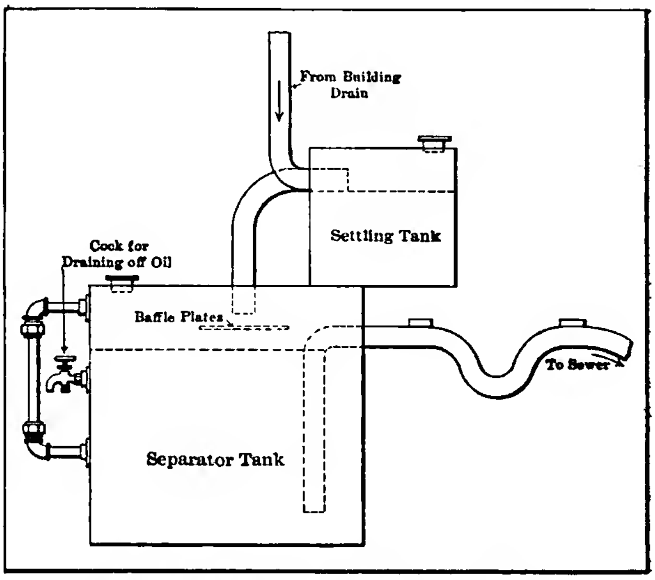


Sewer Trap Tile and Iron Pipe

From another standpoint, this is waste, for the oil and gasoline may both be recovered, and money saved in that way. Of course, this saving is small for the small garage, but in the larger places it is considerable and worth some thought. In the very large public garages it becomes a very considerable item, moreover the waste from such a place is great enough, were it not properly attended to, to endanger the safety of many large business houses using the same sewer. So much is this the case that nearly all large municipalities recognize it and have stringent regulations relative to it.

Many Ways of Solving Gasoline Waste Problem—This has evolved some approved forms of drain, while there are many others of private design which are equally good. On this page are shown three of these, one being the form recommended by the City of Milwaukee. This is actually the most simple and by far the least expensive of the three given.

It consists of two 24-in. sewer tiles, one with a 6-in. tee and the other plain. The plain one is set down into the ground and the bottom filled with concrete to a depth of about 3 in. Into the tee is inserted a bent-iron pipe of 4 in. nominal size, this being bent at a right angle, and the inner end reaching down to within one foot of the bottom. The outer end of the iron pipe leads to the sewer, and as far as its usefulness is concerned, the opening around it, that is between the inside of the tee and the outside of the iron pipe, may be cemented also. To cover the top, a cast-iron cover is made which fits down into the lip of the



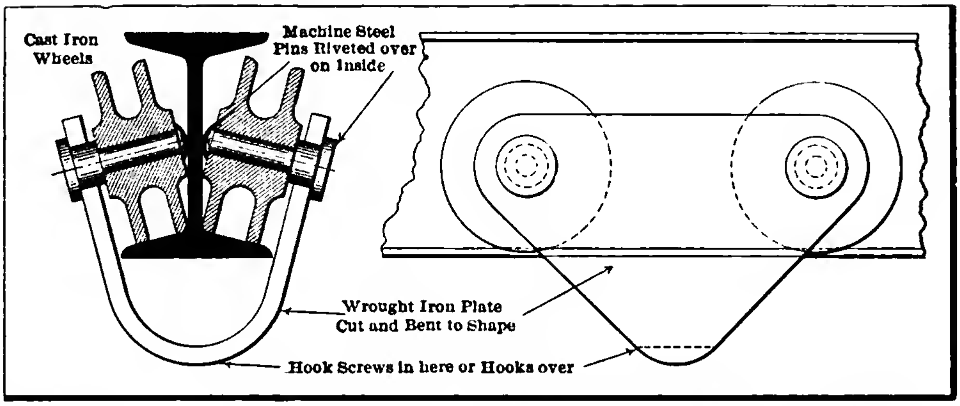
More Elaborate Scheme of Separator to Save Oil

tile, has a removable center with many holes bored into it, and is of itself removable to allow full access to the inside of the drain.

The action is as follows: Water carrying oil and gasoline flows through the perforated cover into the drain, which must fill up to a depth of over 3 ft. 5 in. before any thing will flow off to the sewer. Before this depth will have been reached, in fact at all depths, the oil and gasoline will float to the top. The lesser specific gravity thus prevents either one from going to the bottom of the drain, which is the only place from which the outward flow can begin. Thus, the gasoline and oil must always stay in the drain. The former will evaporate through the perforated cover, while the oil will have to be removed.

Practically the same description of action applies to the other small one shown, which is, however, built of concrete in two sections with bent pipes uniting the first and second, as well as leading from the second to the sewer. The double compartment simply serves as an additional precaution, both chambers working exactly alike. Removable covers allow of access to both, while perforations allow the gasoline fumes to escape as before. This design is so simple and so easy to make that it might easily be incorporated into any private garage building.

More Elaborate Design Saves the Costly Fuel—In the third cut is shown a more elaborate design of a trap which not only does all that the others do, but saves the fuel and oil as well. This form has two tanks, the latter one acting as the separator tank, and carrying a drain cock at the side and near the top, by means of which the floating oil and fuel are drained off at regular intervals. After draining off, another form of apparatus is used to separate the two, but the difference in specific gravity is such as to make this easy of solution, simple settling basins effecting the desired result without any attention.



Suggestion in the Way of Provision for Hoist, and Traveler for Same, Using I-Beam

Speaking of gasoline saving, the whole fuel question is worthy of attention. Thus everyone should have an outside tank for keeping the fuel, but not all can afford the complete apparatus as now put on the market. To attain the same results with a lessened expenditure, the sketch below shows the construction to resort to. There is but one thing necessary other than the tank itself, and that is a source of air pressure, and, of course, connecting pipes to transfer it to the tank outside, and to carry the fuel back to the garage.

As shown, a bicycle or other foot pump A is provided within the garage, this being connected with one end of a pipe to the tank, marked air line B. This leads into the top of the buried tank C, and the pressure of the air within the tank forces the fuel through the other pipe, marked gasoline line D, back to the supply pipe at E. By locating the filling cap F outside, the supply may be renewed at will and without entering the garage.

To use the fuel, all that is necessary to do is to open the cock at E and the one down at the floor. Then pump at the foot pump until the liquid flows at E. By turning off both cocks the pressure may be retained in the tank for some time, so that but a few strokes of the pump are necessary at any one time.

Moderate First Cost Biggest Advantage—Aside from the cost of an air-tight tank, a practical necessity anyhow, the other costs of this piece of apparatus are negligible, consisting only of the two lines of small-sized pipe, soldered into the tank, the two cocks and the foot pump. This would total up very small, so small as to bring the outfit within the means of everyone.

At the top of this page is shown a suggestion to the amateur garage builder, and one that will save him much labor. This is a suggestion in the way of providing for hoisting apparatus while building. If an I-beam, or a pair of channels set back to back, or even an old tee-rail, is set across the building when the latter is going up, it will never be in the way and will always be there for the future. This should be set across the garage in such a way as to be along the center axis of the car, and directly above the center line. In placing it thus as will be shown later, when the block and tackle or other hoisting apparatus is added and it is desired to take out an engine, for instance, the car may set in any old position, while if the beam is set across the length of the car the latter will have to be moved back and forth until the center of the engine weight comes directly under the center of the beam above.

This beam need not cost much of anything, in fact, in many cases, a discarded tee-head rail may be obtained for nothing, and the carting charges will be the sum total of the cost. With the beam in place, when the owner makes up his mind to add the hoist, he has but to put on some form of a traveler to which the hoist may be attached. The sketch suggests one. This is made of a pair of cheap cast wheels, of almost any metal, cast iron being satisfactory. These run on the sloping part of the I-beam, channels, or tee rail, all of which have approximately the same slope, and consequently need some form of uniting piece, which will take the slope into account as well as providing a place for the hoist to hook or screw on, these being the usual methods.

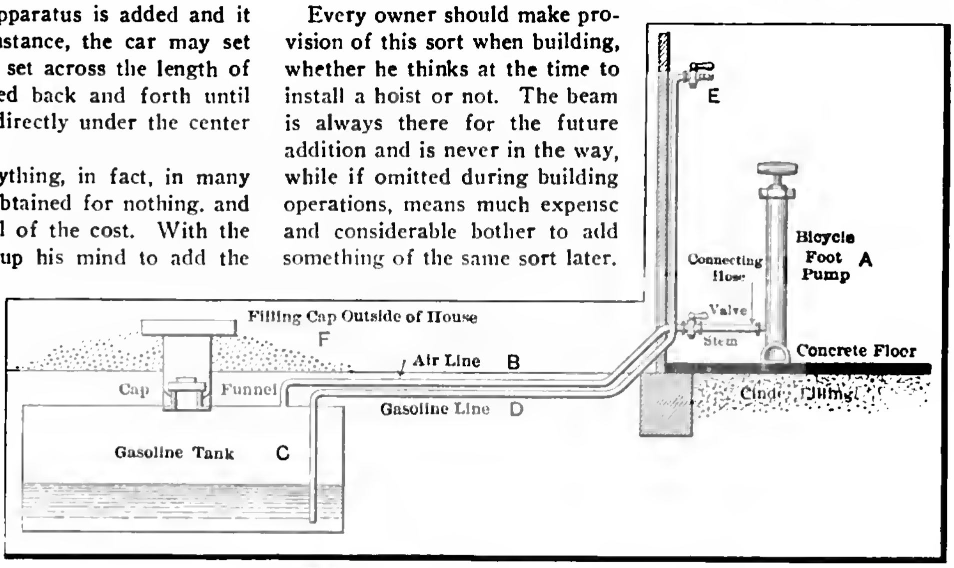
In the sketch this is shown as a wrought-iron plate cut to shape and bent around nearly double so as to present a comparatively narrow base for the hook or screw. In side elevation, the finished and folded plate presents a triangular shape.

Pins of a shape to hold the wheels to the plate are used at the four corners, two on each side, where the wheels are pivoted. The pins are of machine steel, made of good diameter to present a large bearing surface, and with a large head. The inner end may be riveted over to hold the wheel in place on that side. Wheels can just as well be solid, but are shown with a central circular groove so as to reduce weight.

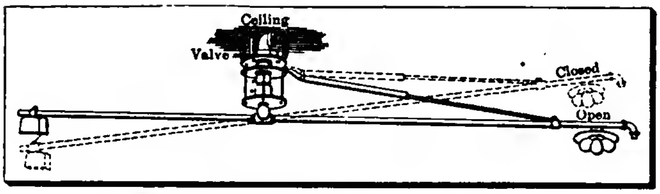
For the hoist, a duplex or triplex chain hoist will answer the purpose very well, and will lift far in excess of the weight of the entire car. For the sake of economy, however, a block and tackle using rope could be utilized to just as good purpose, with the single proviso of requiring a fastening at the traveler more substantial than rope.

By making the distance between the wheels on the side long, the little carriage will run along the beam very easily, and may be slid along to the point at which it is desired to use the outfit, in the usual case at the front end of the car. This form of apparatus does away with jacks and their slow and awkward use, in that it is much easier and far better to slip the hook under the offending part, give a couple of pulls to the rope and there you are. In such a case as removing a rear axle, wheel, or tire, this method allows of hoisting the entire rear end of the car as a unit, so that one or both wheels may be worked upon at one operation. The chain blocks mentioned are self locking, and the block and fall is also supposed to be, but unless many turns of rope are used, practically is not. This is simply a matter of tying the loose end to some convenient post, or a nearby hook.

Every owner should make provision of this sort when building, whether he thinks at the time to install a hoist or not. The beam is always there for the future addition and is never in the way, while if omitted during building operations, means much expense and considerable bother to add something of the same sort later.



Suggestion for Home-Made Gasoline Supply System with Tank Buried Outside



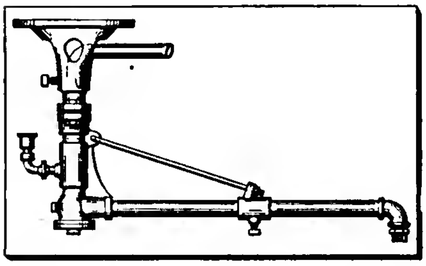
Overhead Washer with Weighted Arm and Cutoff

Another Home-Made Substitute for a Jack—While this is more than a substitute for a jack, handling loads that a jack could not be used upon, as well as working in a different manner, still it would supplant a jack. Another handy substitute for the latter is shown at the bottom of this page, and consists of a simple wooden lever of the first class, that is, with the pivot between the weight to be lifted and the force to lift it.

As shown, it is made of wood, but this need not be adhered to, as metal is equally good and stronger, but, on the other hand, heavier. A so-called sandwich beam would be very good for this purpose, but is objectionable on the score of expense. This consists of a thin plate of metal between two comparatively thin pieces of wood. The wood may be used thinner than otherwise on account of the sheet metal.

This one has a single central piece of wood, preferably of a tough wood, with a smaller rubbing or base piece hinged or hung on one end. To lift anything with it, the low end is hooked under the article, and then by resting the rubbing picce on the floor and pressing down on the long handle, the article is lifted. The dimensions given are only suggestions, and the outfit may be made to any desired figures to fit the individual case.

This is similar to the lift used for changing tires on a racing car, with the exception that the latter has two branches connectcd, so as to form a rectangle in the plan view. This is stuck under either the back or front axle, and by pulling down on the extended rear arms the whole front or rear end of the car, as the case may be, is lifted free of the ground. To make one of the latter from the drawing shown, simply connect the two long arms and the two rubbing pieces, so as to be at the same distance apart. If desired, the two hooked ends may also be connected and at the same distance apart as the others, but this is not necessary to the successful use of the device.



Overhead Washer Not Weighted

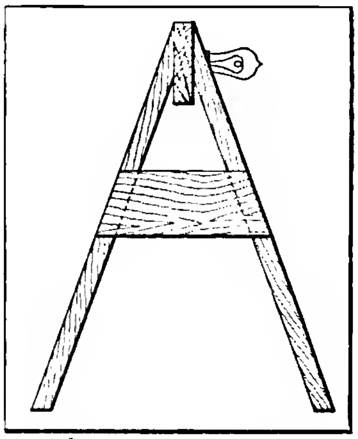
Proper Lighting Very Important—One of the little things which the amateur repairman cannot do without is light and plenty of it. The arrangement of the garage and windows in the same is not always such as to afford this, or it may be that the position of the man when working at the car is such as to shut off the light from the biggest and best window. In cases like this, and when working at night artificial light is a necessity.

For garage use electric light should be used if at all possible, for all other means of lighting introduce an element of danger in that there is and must be an open flame. With gasoline and highly inflammable oils always present this is the height of folly. In laying out the lighting system it is impracticable to try and suit every need, so all lamps should be hung with very long cords. This will allow of moving them around the garage to suit the work being done.

A good thing to have for this purpose is a light stand, one of metal being now placed upon the market, which has many commendatble features. The cross-bar upon which the lamp is hung is adjustable for height and direction, while the stand as a whole may be moved around at will. Many prefer to make their own light stands, thus saving the price of the metal ones. For these a suggestion is given. It is this: to the saw horse, without which a garage would be incomplete, attach a lamp socket in such a way as to allow of the insertion of the lamp on one side and of the socket for the light plug on the other. In nine cases out of ten when working on dissembled parts you will have them supported on saw horses.

Then all you need to do, to have light, is to screw the lamp plug into the one side of the fixture on the horse and the lamp into the other. The lamp should be removable, as it is very liable to be broken otherwise, since horses are treated roughly, while the extension and plug should be removable so as not to tie up any one light.

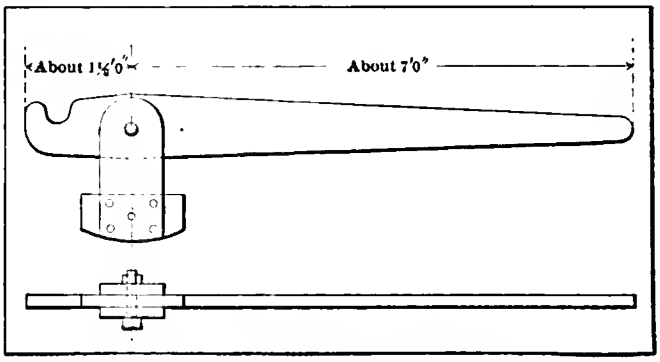
Facilities For Washing Needful and Economical—While nearly everyone will grant that adequate washing facilities are needful, or desirable, few would figure out that they are also economical. This is nevertheless true, for with improved and handy means for washing, the car will be washed more regularly, more promptly and more thoroughly. This applies not alone to the painted parts of the body, but to many of the mechanical parts as well. To cite an excellent example (not a mechanical part, however), the wheels can not be washed too much, particularly in warm weather. Heat opens the joints in the wheels, while plenty of water will cause the wood to swell, thus closing the cracks. This applies to the miter as well as the felloe, to say nothing of the tenons, spokes into felloe.



Suggestion for Garage Light

Granting, then, the need and usefulness of a form of washing apparatus, the qucstion arises which? The overhead washer, two of which are pictured on this page, presents some ideas which cannot be obtained in any other way, and are desirable. This form is always up out of the way, when not wanted, and aided by the hinged joint, may be pulled down for use. The one shown first is weighted so as to balance itself in any position in which it is placed.

In the second one the construction is such as to suggest the making of a washer-using water pipe, obtainable at any plumbing shop. The only problem would be the swivel joint at the pivot point, but the plumber could doubtless furnish a full universal swivel which could be used for this purpose. In that case, making one of these is simply a question of knack with a stilson wrench and other pipe-fitting tools. The corner would be a simple elbow and the angle brace a pair of tees, with the tee end plugged, and the plugs drilled for the wire cable. This, in turn, could be made with turnbuckle in the middle, so as not only to tighten it up at first, but to allow of later tightening, as opportunity presented or as it was found to be needed.



Sketch of Home-Made Substitute for Jack

ONE MAN'S EXPERIENCE ON THE ROAD

By James S. Madison

EVERY new owner and every prospective owner of a motor vehicle ought to realize that there is a strong probability of having an accident on the road sooner or later. It can be mathematically demonstrated that out of 1,000 cars, each making a mileage of 5,000 in a season, a certain, definite number (which is entirely too large) will meet with one or more accidents that will be more or less disastrous, depending upon the special circumstances in each case.

Many owners, before their first ride, have firmly resolved that there will be no accidents, or if one should occur, that it will be the other fellow's fault. This, of course, is right and proper; yet in spite of good intentions and good resolutions, many avoidable accidents, not due to the other fellow, do happen every day.

Further, every owner and every prospective owner should realize that while there is only a probability of accident, there is a certainty that the car will some time stop on the road, or certain contingencies will arise which will render it necessary to stop the car to prevent injury being done the engine, chassis, body, or tires. It is inevitable, inescapable, that something will go wrong sometime, causing a longer or shorter delay, depending upon the seriousness of the cause, the ability of the driver to locate it, and his skill in remedying it when found.

This article is written with the expectation that it will be something of a guide to new owners in aiding them to prevent certain kinds of accidents, and to somewhat shorten the delays which are sure to come to them on the road. The writer has owned a gasoline car for nineteen months—578 days. Of this time the car has been on the road 480 actual days, winter and summer.

At no period (with the one exception of fourteen days required for re-varnishing) has it been laid up for repairs more than several hours at any one time. The reason it was not on the road on the remaining 84 days was due to disinclination of the driver or the unpleasant condition of weather or the roads, and not because the car was out of commission.

While this is not an exceptional record, it is a satisfactory one and is largely due to two factors: First, the sturdiness of the car itself; second, the driver's early experiences taught him to be more or less cautious, so that by far the greater portion of the driving has been done without taking risks, and further because he was willing to give the car a daily inspection, with a very thorough one at least once a week.

First Collision—The owner had driven the car (with the aid of a chauffeur) about 30 miles on his first run. The greater portion of it was in the country where the driving was so easy as to give a false feeling of confidence. On returning to town, it was necessary to go through a crowded street. The point where the congestion of traffic was greatest was up a short grade leading to a bridge narrower than the street.

Everything had gone serenely up to this point. The owner found himself in a procession of vehicles, hemmed in on one side by another procession going in the opposite direction, and on the other by the railing of the bridge. He was going at about six miles per hour with the highest gear engaged, spark retarded, throttle closed as far as possible, foot on service brake. Suddenly the tail-board of the wagon ahead seemed uncomfortably near. He made an effort to stop the car by pushing hard on the service brake.

This was not sufficient, and before it was possible to get on the emergency brake (side-lever), the impact came, resulting in the destruction of two gas lamps. This was caused by two errors on the part of the driver. It was an error of judgment to attempt to take the car through the crowded streets on his first ride. Then, he should have disengaged the clutch. The damage was not great, but the occurrence was annoying. Since then he makes it an invariable rule to throw out the clutch when in doubt. If a beginner will learn to throw out the clutch whenever there is any question in his mind as to what is going to happen, he will save many an unpleasant experience.

Second Collision—The car was passing another on a country road. On inquiring of the other driver the distance to a certain town he told me I was going in the wrong direction. I slowed up, turned around, and as he had stopped along the left-hand side of the road, I ran along at a 15-18-mile clip until I came within a short distance of him, when I threw out the clutch and ran alongside in the middle of the road in order to get some further information.

Just as the car stopped, it was hit behind by another car going in the same direction, which had come up in the rear unknown to me. In this case, my only neglect was not to have raised my arm as a signal that I was about to stop. The mistake the other driver made was to have run so close to me without being prepared to make a sudden stop. The damage was not serious to either car, but this was due to good luck rather than good management. Had the conditions been only slightly different, the results might easily have been disastrous.

Hurry Call for a Pair of Horses—The car had been going along nicely for about an hour, when it was noticed that at longer or shorter intervals the engine lost power suddenly for a fraction of a minute at one time, or for a longer period at another. After limping along for a short space, the car would just as suddenly regain its normal speed. It acted very much as if there had been a sudden gentle and repeated application of the brakes. The brake and transmission bands were examined to discover if any of them were dragging.

Nothing was found. On starting again, the first turn of the crank brought the necessary explosion and the car ran along very well until half way up an 18 per cent grade, when it stopped without warning or symptoms. We could not start the engine again and there was no spark at the timer or coil (non-vibrating). The battery cells on being tested showed 18 amperes. The battery and other connections, primary and secondary wires, were examined without discovering anything. The first motorist who came along courteously offered assistance.

After spending at least half an hour, he decided the coil was burnt out. Being seventeen miles from the nearest garage, and not eager to accept the first diagnosis, since, if correct, it would necessitate a pretty severe operation, we waited for the next tourist. He was also obliging enough to give us about twenty minutes of his time. He concluded it was a burnt-out coil. Since the afternoon was young and the June air balmy, it was decided to hold up several more autoists.

Four others came along at intervals and were interviewed, but I was unwise enough to tell each one of them that the preceding ones had decided that the trouble was with the coil. They all agreed that this was it. There was nothing to do but to go across the fields after a farmer, who arrived with two horses about an hour later and towed us to the nearest village, where we spent the night.

Before turning in, a telegram was sent to the garage man describing the difficulty and asking him to bring a new coil early in the morning. He arrived about nine o'clock and his first statement was to the effect that he had been in the business for ten years and had never seen or heard of a coil of that particular make being burnt out or breaking down from other causes; and further, that before he looked at the coil he would go over the whole engine.

Without asking any questions, he examined the timer and found, as I had, that there was no spark. Next he tested the batteries and declared them all right, and then announced that there was a broken connection somewhere. He found it in about three minutes, but a novice might have looked for it a whole day without discovering it, because it was most effectively concealed in the switchboard which extended through the dash. The portion nearest the driver consisted of a hard red rubber circular plate containing two round holes for the plug to make connection with battery A or battery B as might be desired.

This plate was fastened to the dash by three screws. To the other side of the plate, which was not visible, there was fastened, also by screws, a hard rubber cylinder about 1 inch in diameter and 1 1-2 inches long, perforated lengthwise by two brass tubes, 1 1-2 inches long, for the introduction of the round switch plug. The top of the rubber cylinder (the end nearest the plate) was covered with a circular brass plate, to which the two brass tubes were attached.

Fastened to this circular plate and running along the side of the cylinder was a strip of brass 1 3-4 inches long and 1-2 inch wide. It had been secured to the brass plate by solder and to the rubber cylinder by a screw. To the lower end of this strip was attached the wire which led from the switch to the coil. The whole trouble was caused by the soldered joint between the strip of brass and the circular piece of brass working loose.

In spite of the fact that the strip was secured by a screw, the vibration of the car (or something else) had caused it to separate sufficiently from the plate to create an almost invisible crack across which the current did not pass. So since the connection to the coil was broken, there was no current passing to it or through it.

While I was greatly chagrinned to find out how simple the fault really was, the lesson that I learned was that I must study the whole car more thoroughly, so that I need never be obliged to depend upon the opinion of the chance passer-by. This I did within three days, taking apart certain portions that were ordinarily out of sight. The information gained was worth more than the trouble involved. I have not been held up since, nor do I expect to be, without being able to determine the cause.

On the occasion above referred to there were seven automobilists who could not distinguish between a broken connection and a broken-down coil. There must be many others.

Irregular Explosions—On one occasion, after running forty miles, the engine began to miss. There was an easily-perceptible interruption of the rhythm of the explosions, though the car was kept going until several sharp cracking explosions were heard, evidently in the muffler. Upon stopping and looking for the cause, it was discovered to be a loose connection between two cells of the battery. One of the small brass thumb screws had worked loose and dropped off, leaving the wire attached to the zinc terminal to move about with the motion of the car, thus causing temporary and repeated breaks in the primary circuit.

Another case of missed explosions occurred the next day. The symptoms were the same and naturally I expected to find the same cause. But after going over all the battery, coil, and timer connections, I found everything right with a good spark at the timer. I therefore knew that the difficulty lay somewhere in the secondary circuit—the coil and its connections leading to the spark plugs. With my previous experience in mind, I concluded to let the coil alone and inspect the spark plugs. I soon discovered a very minute crack in one of the porcelains through which the current escaped forming a short circuit and thus preventing firing of the charge in the cylinder.

Perhaps the most common cause of missed explosions is weak batteries. The following experience has happened a number of times and is typical. The car was going up a hill when a single miss occurred. Just before reaching the top, about a quarter of a mile further on, another one was noticed. The distance from this point home was about five miles of level road. There were no more misses. The next day they occurred again. The engine missed fire eight times, the next day the number increased, and on the fourth day, on the last 1 1-2 mile of a run, they came so often as to render it somewhat difficult to get home. I knew all along what the trouble was—weak batteries—but I wanted to run them down. When they were tested, three of the eight cells showed 0 amperes, and none of them showed above 2.

There are other causes for missed explosions, but the three just referred to will cover the greater portion of all that occur.

Engine Stopped Suddenly—The car had been running about an hour when without any preliminary warning or suggestion of trouble the engine stopped firing. I knew at once that it was due either to no gasoline in the tank, or that the fault lay in the ignition system. A glance into the tank showed a good supply of fuel. On cranking the engine there was no explosion.

Next I found there was no spark at the timer. I then began to examine the battery for a broken connection. I found a broken wire and it was a matter of two minutes to cut away the rubber insulation from each end for about an inch, bend the protruding wires in the form of a U, hook them together, twist them with a pair of pliers, and wrap the joint thus made with electric tape. This ended the difficulty.

Trouble with the Carbureter—For five days the car ran sluggishly on hills. The engine acted as if it had lost about half its power. It stopped several times, in each case on a hill, and I could only get it to go after fussing about it for fifteen to twenty minutes. I thought the trouble might be due to some unknown chemical action in the interior of the battery cells, which prevented a full current being delivered when a heavy demand was made upon it—in going up hills, for instance.

I was led to adopt this view of the matter largely because the engine could be started after it had remained idle for some time, thus apparently giving the battery time to recuperate, if the trouble were there. I put in eight new cells, but on the first hill I tried the same thing occurred. I then began experimenting with the spark and throttle levers—the car standing still, the engine running. With the throttle almost closed and the spark advanced, the results were satisfactory.

Just as soon as I opened the throttle wider, however, the engine began to slow down and finally stopped. This was clear evidence that the gasoline was not flowing properly. The carbureter was then removed and carefully inspected, and the cause of all the trouble soon found. A grain of sand about half the size of an ordinary pinhead was lodged in the tube closed by the needle valve. The grain was just small enough to permit sufficient gasoline to pass to keep the car going on level stretches, and large enough to prevent a sufficient quantity from passing when the engine needed a larger supply on the hills.

That grain of sand cost me $3, and it got into the tank through the carelessness of a garage boy who, when he filled the tank, placed the screw-cap bottom downwards on the top of the tank, where there is always an accumulation of sand and dirt, and then replaced it without wiping it off. Since then, whenever the screw-cap is removed from the tank, it is placed bottom upwards on the adjoining seat.

Loss of Power—When the engine was cranked in the morning it started off more slowly than usual, and uncertainly. After the car was started I found it necessary to advance the spark and open the throttle wide in order to get a speed of 10 miles per hour. This did not last long, as the engine stopped, and on cranking, refused to go. My first thought was that the compression was faulty, but this, on trial, was found to be excellent.

Once more I turned to the battery box, which also housed the coil. The only thing I could find disturbed was a piece of ordinary black oilcloth that had fallen from the top of the box across two brass thumb screws of the coil. The shining surface of the cloth was partially short-circuiting the coil, thus preventing a portion of the current from reaching its proper destination. An acquaintance had a similar experience, except that the disturbing cause was a bouquet of flowers which fell across the two coil terminals.

Loss of Compression—I have had but one case of lost compression. On cranking the engine, the handle moved so easily as to show at once that there was no compression in one cylinder. I first examined the inlet valve springs, and then the valves themselves. Next the gaskets, then the spark plugs. Everything was right. On inspecting the exhaust valves, one was found to be loose, and upon tightening it with a wrench the trouble vanished.

Difficulty in Starting—One day twenty minutes were spent in getting the engine started. There was plenty of spark and gasoline, but the explosions would not come. Finally, after giving the starting handle a strenuous pull, the engine started. The car was run thirty miles without a single miss. I then stopped for luncheon, and upon attempting to start again, the same difficulty was encountered. For two days this state of affairs existed. I went over the entire ignition system, batteries, coil, switch, spark plugs, timer, and all wires; the carbureter was removed and thoroughly cleaned; all the valves, gaskets, joints, intake tube, etc., were carefully inspected, without any satisfactory result.

After studying the matter it occurred to me that the mechanism controlling the timing of the spark might have shifted. I soon discovered that the position of the timer on the cam-shaft had been changed, owing to the loosening of a set screw, about 1-8 inch, so that the spark was considerably retarded. Upon adjusting the timer, the engine started off on the first turn.

Ditched at Last—Going over the sandy roads of New Jersey, not far from Lakewood, I attempted to make a turn. The roadbed, while sandy, was hard and somewhat narrow. In order to make the turn I ran off to one side upon what seemed to be equally hard ground. I was mistaken, for as soon as the right wheel struck it, the sand gave way and the wheel sank about six inches. I attempted to get out by using my own power, but this only made matters worse, so I had to start in on a new line of tactics.

Both right wheels sank deeper until there was only a half inch clearance. I then dug a small furrow in front of each wheel, placed a board from a nearby fence as far under each wheel as I could get it, and started the engine. Upon throwing in the clutch carefully the driving wheels spun round, but the car did not budge an inch. Afraid of injuring the tires, I gave it up and sent a small boy to the nearest garage, about a quarter of a mile away, for help. In a short time I was back on the road by the aid of the garage car and a rope.

Two Sets of Tires—The car has had two sets of tires of the q.d. type. The first set was defective, and, in addition, too small for the weight of the car; consequently, they wore rapidly and gave a mileage of only 2,400. The second set was larger by a half inch in diameter and a half inch in cross section. At this time they have given 3,400 miles and appear to be good for two or three thousand more. In all this distance travelled, 5,800 miles, there has been no tire trouble of any description on the road, with the exception of one puncture, a result which may easily be attributed to the careful inspection they receive at short and definite intervals.

Whenever the car is brought in from a trip, I run my hand over the surface of each tire in order to discover any cuts or dig-outs, nails, tacks, etc. Whenever a cut that goes through the rubber to the fabric is found, it is vulcanized immediately, if possible, or in any event, not later than the next day. If a driver will acquire the habit of running his hand over the tires as suggested, he will be surprised at the number of tacks, nails, pins, broken wires, etc., he will find, each of which will usually result in a puncture, sooner or later, if not removed.

THE AUTOMOBILE CALENDAR

Shows and Meetings.

Dec. 25-Jan. 1....Columbus, O., Automobile Show, Columbus Automobile Club.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 4............New York City, Automobile Club of America. Annual Meeting, Society of Automobile Engineers.

Jan. 5............New York City, Waldorf-Astoria Hotel, Annual Meeting Motor and Accessories Manufacturers, Inc.

Jan. 7............New York City, Manhattan Hotel, General Meeting Manufacturers' Contest Association.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 13...........New York City, Engineers' Society Building, Adjourned Meeting, Society of Automobile Engineers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows' Building.

Jan. 17-22........Kansas City, Mo., Annual Automobile Show of the Motor Car Trade Association of Kansas City. P. S. Sutermeister, Secretary, Midland Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens, Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Jan. 24-31........Washington, D. C., Convention Hall, Automobile and Aeronautical Show, Automobile Dealers of Washington. B. R. Johnson, Manager, 1313 New York Avenue, N. W.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South Street.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Secretary.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

March 12-19......Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

March 21-30......Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Manager, 760 Main Street.

Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Races, Hill Climbs, Etc.

Dec. 22-29........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

Feb. 4-6..........New Orleans, Annual Mardi Gras Speed Carnival, New Orleans Automobile Club.

PROJECTED TIRE CHANGE

Editor THE AUTOMOBILE:

[2,124]—Will you kindly give me a little information on the following subject, through "Letters Interesting, Answered and Discussed?" I am contemplating the purchase of an OO 20-horsepower White steamer, but think the whels are too small, as they use 32-inch by 4-inch tires on the 1910 model. Could I have demountable rims put on and by so doing use larger tires, say 34 by 4? Also, how much power would be lost by this change, that is, if the gearing was not changed. X. X. O. B.
Portland, Mich.

In the Nov. 25 issue of THE AUTOMOBILE, on page 937, we published a table of the sizes of rims which the various styles and diameters of tires call for. From this table it is apparent that your 32 by 4 cylinder tires have rims which are 23 11/16 in. in diameter. Now, on these you may put some one of the following demountables:

34 by 3 1/2	Fisk	demountable	Rim	Size	23 3/16
34 by 4 1/2	Firestone	"	"	"	23 31/32
	Continental	"	"	"	23 59/64
34 by 5	Continental	"	"	"	22 59/64
36 by 4	Fisk	"	"	"	24
36 by 4 1/2	Fisk	"	"	"	22 13/16

None of the 34 by 4 demountable sizes seem to be close enough to your rims to allow of their use. When the rim is too small, a steel band can be shrunk on, and when the rim is too large, the excess may be turned off, in both cases providing the difference is not too great. In the six cases given you will have to: (1) turn off a piece 1/4 in. thick all around; (2) turn off 9/64 in. all around; (3) turn off 15/128 in. all around; (4) add a band 49/128 in. thick; (5) turn off 5/32 in. all around; (6) add a band 7/16 in. thick. That is up to you.

As for the projected change from 32 in. diameter of wheels to 34 in. diameter wheels, the only change which this will make is to increase the speed of the car, as the engine in question will stand "the racket." The increase would be 6 1/4 per cent. at all speeds; that is, the speed of the car with 34 in. wheels would exceed the speed of the car with 32 in. wheels at any one given engine speed by 6 1/4 per cent. Similarly, the change to 36 in. wheels will increase the speed 12 1/2 per cent. over the 32 wheels and 5 3/4 over the 34 wheels.

If the power of the engine were so close to the actual requirements as to lose by this change, the loss would be the exact proportion given above as a gain.

MISTAKEN IGNITION IDEA

Editor THE AUTOMOBILE:

[2,125]—With Maxwell, Moline, Cadillac and half a dozen other well-known manufacturers changing from high-tension to low-tension ignition, you do not say a word about it in the columns of "The Automobile." Why don't you tell your readers something about this wonderful change of heart?

We thought the high-tension magneto almost universal in this country as well as Europe, and surely would like to know why so many manufacturers are changing on their 1910 cars. Please let us know why this change is made. J. B. SMITHE.
Washington, D. C.

As it is ordinarily understood, high tension means the use at the cylinders of jump spark plugs, which are furnished with a high tension current. On the other hand, the ordinary idea of low tension is the use of make and break plugs furnished with a low tension current. If this is your understanding of the two systems, you are absolutely wrong in your statement that many manufacturers are changing from high to low tension ignition.

In fact, the only changes which have been made in this direction in the past two years have all been in the opposite direction; that is, from low to high. So far has this tendency carried that to-day it is a matter of extensive searching to find more than a half dozen makers all told who use the low tension, while all the rest of the 350 or more manufacturers use high tension. More than this, several of the cars included in this statement have also fitted the high tension as an auxiliary, so that the number using low tension exclusively would be less than a half dozen.

On the other hand, you may have been splitting hairs, in that you meant to distinguish between a true high tension magneto delivering a high tension current direct to the plugs and a low tension magneto delivering a low tension current to a coil, where it is stepped up to a high enough tension to jump the customary gap. If this was your idea, in that also you are absolutely mistaken, as the tendency seems to be toward the self-contained and self-complete magneto producing a high tension current direct to the plugs.

STOPS RADIATOR LEAKS

Editor THE AUTOMOBILE:

[2,126]—I have an aluminum radiator on my automobile, which is leaking slightly, probably half a gallon in half a day. Do you know of anything that could be put in the water so as to stop this leaking? Shop men think that it would be hard to solder. I douht if it leaks in more than four or five cells, and it may be confined to one.
Bainbridge, Ohio. A READER.

Aluminum can be welded—that is, soldered—but this work is not done by every one, and if you decide to have it fixed in that way be sure to go to a specialist in the line of aluminum. Otherwise you are liable to pay for a good job and get a poor one.

As for filling it from the inside, this can be done, but is a makeshift job at best. In a letter published in the Dec. 2 issue of THE AUTOMOBILE you will find that a writer says of a 25 per cent solution of glycerine in water, used to prevent the water freezing up in cold weather, that it forms a jelly which fills up all small leaks.

This being the correct time of year to resort to anti-freezing solutions, you might try this, but when warm weather comes around again you will be confronted by the leakage problem. That being the case, why not have it properly attended to now?

CRANKSHAFT TROUBLE

Editor THE AUTOMOBILE:

[2,127]—I have read your column of "Letters Interesting, Answered and Discussed" for some time, taking great pleasure in so doing. Now, I wish to ask a question referring to a two-cylinder opposed motor of standard make, water-cooled.

This engine is hung on a subframe, with the crankshaft extending out from the crankcase. The transmission is assembled on this extension of the shaft, which is in one piece and as a bearing at each end. This engine has broken three or four crankshafts. In the last two we took care to see that the bearings were all lined up perfectly. When through, the engine ran true without binding at any bearing. The engine usually runs about three or four months in each case before breaking. Every one of the shafts broke in the same place, the crank part of the shaft. On the last one it looked as though the metal might have crystallized. Can you give me some pointer as to where to look for the trouble. A SUBSCRIBER.
New York City.

It would be hard to diagnose the trouble from your description, as, for instance, what is the crank part of a crankshaft? However, we think from the scant description that you have a case in which the load is applied outside of the bearings; that is, the loading is eccentric.

This should never be; there should be a bearing on each side of the load, not alone from a mathematical consideration of the fact that this reduces the bending moment to one-fourth and the shear to one-half of what it would be with the same load overhung, but from strictly common-sense reasons.

Although you do not say exactly, we surmise that there is no bearing beyond the transmission. If this is the case you should have a new shaft made, with a prolongation beyond the transmission. Then you should make a bearing for this prolonged end, making it adjustable if possible. You will then have a bearing on each end of the crankshaft proper, and a bearing at each end of the part used as a main shaft for the transmission; that is, considering the one engine bearing in each case, once as an engine bearing and once as a transmission bearing.

If the engine and transmission are set across the frame, as we surmise, you can easily attach this extra bearing to the frame on that side, using care in the length of the new shaft, so as to have it long enough to reach to the frame. When this is done your trouble will entirely disappear; that is, if the size of the shaft, considering the material of which it is made and the work it has to do, is sufficient. If this is not the case it will continue to break, whatever you do.

Crystallization, of which you speak, might occur once, or at the outside, twice, but it is improbable that it would occur four or five times in the same place.

ANSWERED AND DISCUSSED

SOLVES W. T. K.'S TROUBLE

Editor THE AUTOMOBILE:

[2,128]—In "The Automobile" for Nov. 18, I find that W. T. K., Nichols, Conn., inquires as to the effect of 1/8-inch space between valve stem and valve lifter upon the power of the motor. Your information on this point does not coincide with my experience with this very trouble. I have a little "one lunger" Olds, which was in very poor condition in respect to valves when I took it in trade. I could get no speed out of it. After figuring on the thing, after having it at several repair shops, and several times, too, with no better result, I put a new cam on the time shaft or rod. Even then, I was going slower than other machines of the same make and type.

I then noticed the play between the valve stem and lifter, and after thinking it over, decided the higher the valve was lifted in the explosion chamber, the quicker the cylinder would exhaust after the combustion, and naturally there would not be as much obstruction or load for the flywheel to work against. The intake valve, I reasoned, would take in a bigger charge the higher it was lifted. To take out both valves is quite a job, so I took layers of tin and shoved them in between the valve lifter and stem, leaving about the space of one piece of tin. To hold these in place, I next cut a piece of tin about two or two and a half inches square, cutting out the corners so as to leave it in the shape of a cross as per enclosed sketch. Then I cut along the dotted lines, and shoved it under the stem. Filling the space above it with as many thicknesses of tin as were suitable, I turned up the four sides, pressing the ends under the coils of the spring where possible. To do this I had to do one end of the cross at a time, as follows: Turn up the first side, place the tin washers in position, turn the whole thing to the right 90 degrees, turn up the second side, turn again to the right, turn up the third side, then turn to the right again and turn the last side. Before the last side is turned up, all of the layers of tin desired must be inserted inside of the little basket formed by the folded up cross. When I took the car out after doing this, well, she ran in such a way as to give some pleasure to me, and I judge that I had gained from 25 to 30 per cent. in power and speed.

As to W. T. K.'s machine pounding when hill climbing, I think he has the spark too far advanced. My car will not pound on the level at a certain speed, but when I climb up grade and the speed is materially reduced, and I leave the spark unchanged, the pounding begins. This is due, no doubt, to too early explosion. If I have erred in analyzing the matter, I am always willing and glad to be corrected. F. W. K.

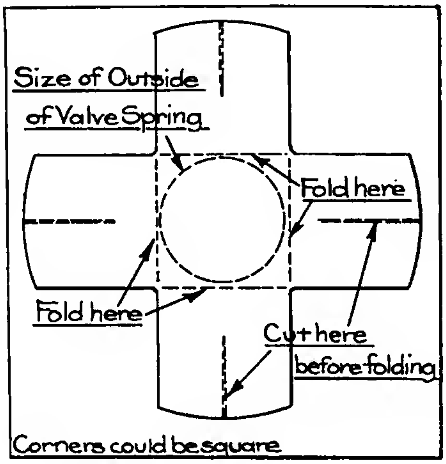
Los Angeles, Cal.

As your power and speed were not measured, we are forced to take your estimate of the very large increase as a very rough guess. In our letter to which you refer we stated in part as follows:

"The way in which it will influence the power is this: when the adjustment is used to reduce the space and with it the noise, the timing of the valves will be altered slightly, and this slight alteration *may be such as to change the power.* For instance, the engine might have a rather late exhaust closing, which the adjustment would make still later. This, then, would cause the motor to heat and thus lose power. Similarly, the adjustment for the inlet valves might cause them to close either too early, making the charge incomplete, or too late, so that some of the charge was lost, also making it incomplete."

What you did was to alter the timing, just as we said decreasing the space would do. Your situation was such, however, that this alteration of the timing improved matters; that is, by opening the exhaust earlier you cleaned out the cylinder quicker, which aided in the increase in power. Also, opening the inlet earlier allowed you to take in a larger charge, which helped the power.

Cases have been known—the writer knows of several—in which this change reduced the power developed. The engines, however, were modern engines with fairly good timing. The changes in the clearance were such as to make both valves open too early, so that the exhaust opened too quick, losing the effectiveness of part of the



Cross-Shaped Tin Used by F. W. K.

power stroke, while the inlet opened so early as to allow much of the exhaust gas to flow into the inlet pipes and thus foul the incoming mixture. The effect of this on the power can be imagined.

Or, if your imagination is not good, try it on your engine, that is, turn your camshaft driving gears back one or two teeth from their present position, and note the effect. As a matter of fact, correct timing has as much or more to do with the power and speed which an engine will develop, as has the correct size of valve and valve ports, together with the proper lift of the valve. If the timing is correct, you can help power and speed by increasing lift and area of valve opening, and similarly, if the valve port area and lift are well chosen, the resultant power or speed, or both may be greatly increased by carefully improving on the previous timing relations. All this on the assumption that the engine (as in your case) is an old one, dating back before the present valve timing knowledge was prevalent, which as a matter of fact would take you back but five years.

MYSTERIOUS SKIPPING

Editor THE AUTOMOBILE:

[2,129]—Will you please give me, through the columns of your paper, a suggestion for the following trouble: I have a Buick, Model 10, 1908 pattern, which has run perfectly until recently. Now the engine skips both under load and empty. I have newly charged storage battery, new dry cells, wiring seems good, all connections are tight, valves have just been ground in, cylinders recently cleaned of carbon, compression is good, and alike in all cylinders, intake manifold has no leaks, have tried new spark plugs, have cleaned the timer thoroughly. The timer shows no wear, and looks to be in perfect order. The timing is the same as when the car was received from the factory. This engine is fitted with a Kingston carbureter of the ball type, which has just been overhauled at the factory. Gasoline flows freely to the carbureter, and I have drained the tank and refilled it with fresh gasoline, carefully strained through chamois. The spark seems very good when the plugs are tested in the open air. I might say finally that the motor runs the same on each cylinder, as proven by holding down any three of the vibrators. BONARD DAIN.

Lawrenceburg, Ind.

You have covered all of the possible sources of trouble of this kind, so that it seems as if you must have taken some of it for granted. Thus, you say that the wiring *seems good.* Are you absolutely sure that it *is* good? The wires might be broken somewhere within the insulation, so that the break was not apparent. You know, the exterior of ignition cables is usually examined, but as a matter of cold, hard fact, the exterior does not do anything at all, the interior being the working portion.

You do not seem to have mentioned the inlet valve guides in the cylinders. Do these fit tight, so that you could be sure no air leaked in through that source? If you cannot, that is a frequent source of trouble.

Your last statement that the motor runs the same on any one cylinder, as proven by holding down any three vibrators, would seem to show that the trouble was back of that point. This would mean that it was either in the coil itself or back of the coil. The latter would include the two batteries and the wiring from each to the coil.

Borrow a coil, known to be all right, from some friend, substitute it for yours, and see if the same trouble exists then. If it does, that test exonerates the coil and reduces the other items to four, the different batteries and their respective wiring systems to the coil.

Moisture is frequently absorbed into the interior of a coil, practically ruining it for the time being. Knowing this to be the cause of an incipient short circuit, the coil can be dried out before a slow fire, or in what is called a slow oven, making it then as good as new.

SOLUTION OF TROUBLE

Editor THE AUTOMOBILE:

[2,130]—I want to compliment you on the contents of "The Automobile." Every issue seems to be better than the rest. I received a copy of another motor car paper the other day, and must say that there was as much comparison as between the cheapest of the cheap magazines and the Review of Reviews.

Kindly inform No.......... who has trouble in starting his two-cylinder which has a puddle carbureter, that he described my trouble for the last two years, but now have it cured and guaranteed to stay cured as far as I am concerned—sold the machine—go thou and do likewise!

Ashtabula, O. HOMER P. SMITH.

Individuality Imparted to Automobiles

By Thos. J. Fay

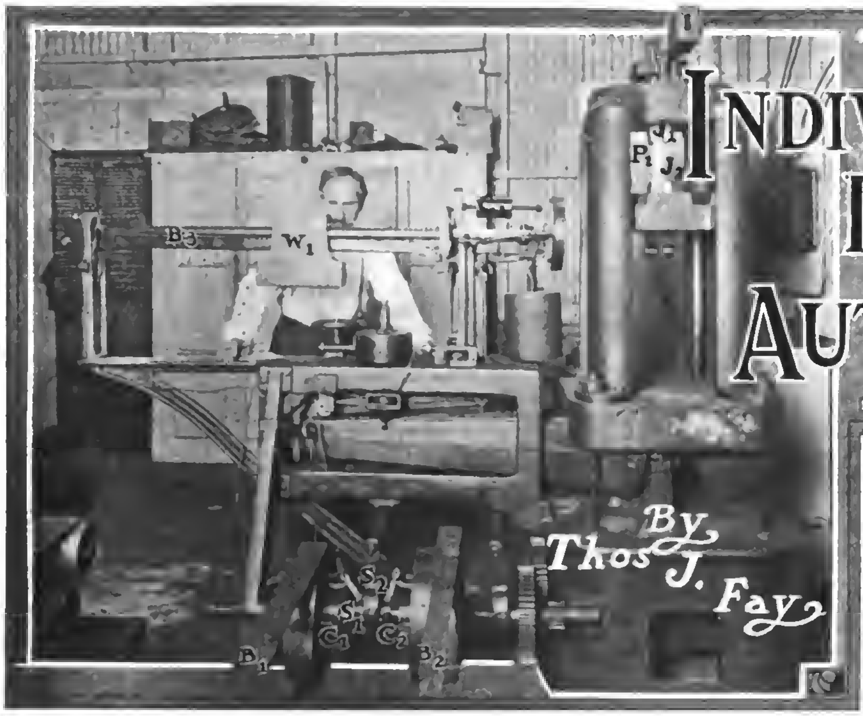


Fig. 1—Olsen testing machine for use in determining physical properties of materials used in Rambler cars for best results

STRUCTURAL materials look very much alike to the casual observer, and referring to steel in particular, it is even difficult for the most skilled metallurgists to discriminate as between the several conditions in which the material may reside. In view of this mal-situation, considering the importance of quality in a kinetic machine, as an automobile, it is scarcely to be expected that quality will be conspicuous in the absence of precision of method, and method itself is reduced to mere desire when the facilities available fall below a certain level.

If it is desirable to select the testing equipment for a given plant, in the light of the work to be done, it becomes necessary in any profitable discussion to take some complete plant as an illustration of the points to be made. True, there are certain features that may be common to all, and in the hands of men of great skill it is even possible to foresee that deviations may be improvised to accomplish specific purposes, even though the facilities may not be up to a fitting requirement. In the long run, however, the best results will obtain if the facilities are contrived in the light of exact knowledge of the service to be rendered; and in the plant of Thomas B. Jeffery & Company, Kenosha, Wis., which it is the purpose here to use as a concrete illustration of the points to be made, the entire system of testing in vogue is being worked out to accomplish just the results that Thomas B. Jeffery purposes delivering in Rambler automobiles.

New Laboratory Much More Commodious—Before launching into the details of the process, it may be well to say that prior to the erection of the new laboratory which is now being whipped into shape the various tests were made in the several departments, to a considerable extent under the direction of departmental heads, but as the process is now being evolved, all testing of every character will be done in the general laboratory under the direction of Thomas B. Jeffery, thus enabling him to direct the staff of assistants to a greater extent than ever before, and owing to the specific character of the facilities and the gathering of all the processes under one roof, it is a reasonable expectation that the increased output of the plant, which is growing at a rapid rate, will be handled far more promptly.

Consistency Is a Jewel in Testing Work—If it is conceded that it is necessary to test motors at all, it must be allowed that it is desirable to test every motor made. If it is an advantage to run one motor for a time sufficient to eliminate undue fixed losses, it is equally a gain to run all motors made long enough to bring them, respectively, up to the standard set by testing one motor. Individuality in an automobile is only assured provided every unit in each car is given individual attention on the part of the skilled men who are capable of ascertaining as to the maximum attainable results when each unit in one car is tested in a laboratory.

The difference as between a laboratory and a test room lies in the extent of equipment available for the specific work; if the equipment is in presence sufficient to investigate one motor at a time, it is a laboratory process pure and simple, whereas, if this equipment is duplicated as many times as may be necessary to test the entire output of a plant, day after day, the laboratory becomes a test room, as it were; and comes a test room, as it were, in every sense of the word, and

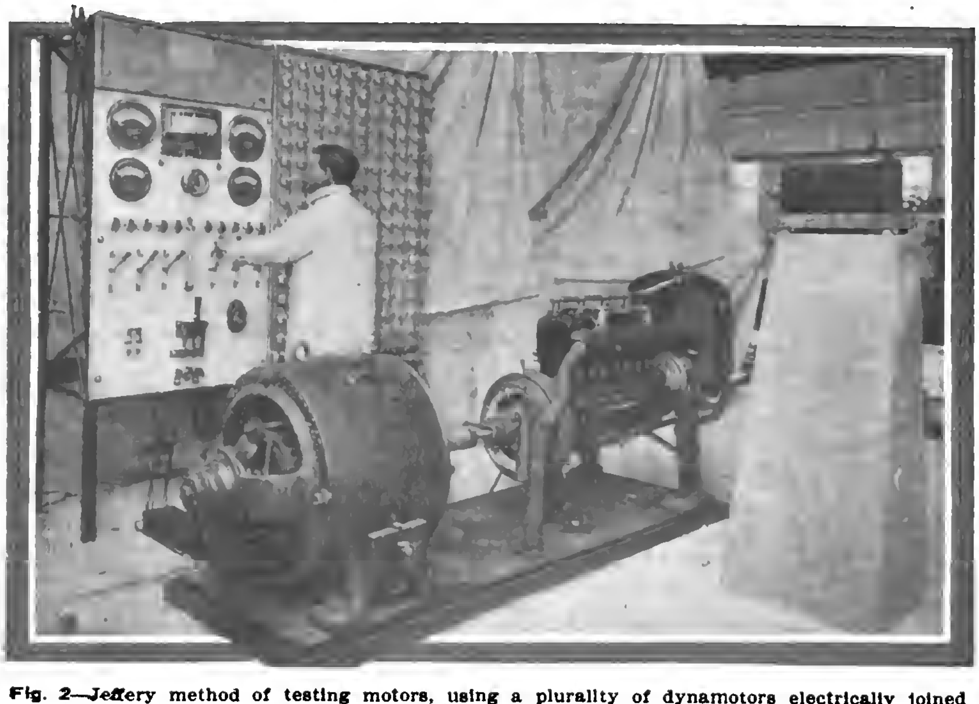

Fig. 2—Jeffery method of testing motors, using a plurality of dynamotors electrically joined and in compensation for economy's sake

if the equipment is just that required for a laboratory, it is then that tests may be made on a laboratory basis.

Sharp Lines Must Be Drawn Betimes—In a laboratory on a large scale (which is what the Jeffery plant comprises), it is necessary to distinguish as between the class of investigations which have to be made in order to keep abreast of the times, and the proving-out process by which the manufactured product is given its final O. K. This phase of the problem is cared for by properly classifying the work somewhat as follows:

CLASSIFICATION OF TESTS TO BE MADE.

(A) Investigations of materials as offered to determine as to the advantage of considering them for future use.

(B) Investigations of materials purchased for use, to determine as to their competence in view of the terms of the orders issued for their delivery by the vendor.

(C) Investigations of parts and operations on parts in process in the shop, to ascertain as to the character of the work being done in the shop.

(D) Investigations of assemblies, as motors, transmissions, live rear axles, steering equipment, etc., to check up quality, ability, and efficiency.

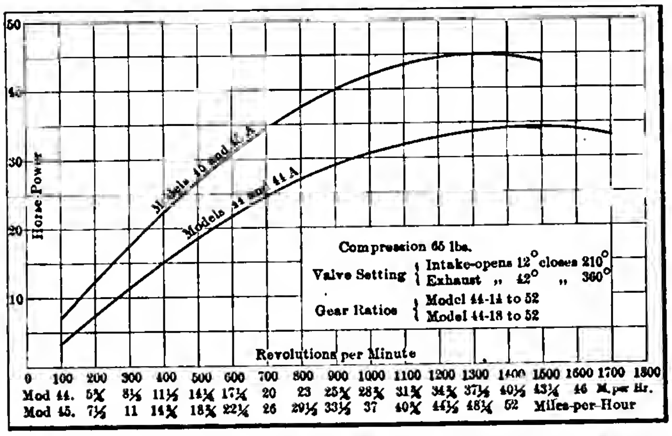

Fig. 4—Torque Curve of models 44 and 45 motors, presenting power for speed at different speeds

(E) Investigations of processes, to improving quality, increasing production, and assuring greater interchangeability.

(F) Final tests of units, as motors and the finished automobiles.

In Class A the nature of the investigations is on a strictly laboratory basis, in which, with a view to future improvement, it is the desire to determine as to the accuracy of claims of vendors, for materials which are not regularly on the market but which promise more than is obtainable in the regular way. This class of work demands the service of a skilled investigator who is capable of discriminating as between the several products in a commercial, as well as a physical, sense, on the ground that while a thing may have more than a little merit, even so, if it cannot be had with certainty, it is scarcely worth considering.

Class B products have to be investigated in order to ascertain if they are up to purchasing specifications, not so much because the price agreed upon should fix the measure of value of the products delivered, but in order to maintain the standard of value of the automobiles to be made from that material.

Class C takes into account the inspection of parts being manufactured, and requires that every operation be scrutinized in order that there will be no incentive to use a part that falls below the standard set, which would be true were it found after much work had been done that some operation was not performed properly. The cost of operation inspection is less than the cost of replacing parts spoiled, and this class of work is performed by men who are skilled in one branch of testing only.

Class D is in the nature of a laboratory undertaking, limiting the testing to "first units" prior to the manufacturing process involving quantity, and in this undertaking it is necessary to

Fig. 3—Hydraulic testing equipment and method of its use in testing for strength and tightness

employ the best skill of the laboratory as accessory to the calm, deliberative judgment of the executive head. Tests such as these demand consideration from every angle, and Thomas B. Jeffery takes personal charge during periods such as this.

Class E ranks as an extra, is most in vogue during the year previous to the putting out of a new unit, reflecting the intention of the company to be positively up to date in the matter of the selection of materials to use in new models.

Class F takes rank as the final test, and in this effort individuality is imparted to the respective automobiles put out.

The Character of the Testing Equipment Employed—An Olsen testing machine as depicted in Fig. 1 is used for making Class A and B tests, and the capacity of the machine being 100,000 pounds total effort is sufficient for every purpose. In this process, after the test proofs P1 are machined to proper size, they are inserted in the jaws, J1, when power is applied by means of the belts, B1 and B2, to the counter-shaft, S1, which is given right or left-hand rotation by means of the shifting lever, S2, engaging the clutching members, C1 and C2, thus engaging the right or left-hand rotation at will. The total effort required to part the proof, P1, is registered on the beam, B3, and the sliding weight, W1, is adjusted in such a way as to keep the beam level at all times. A compensating adjustment is available at C1, by means of which the beam is properly balanced before the test is started, and facilities are afforded for charting the characteristic of the metal undergoing test, in order to record the data required for the purpose of ascertaining the modulus of electricity, elastic limit, and elongation.

In the regular course, in view of the many characteristics which may be imparted to steel by heat treating, it is of the

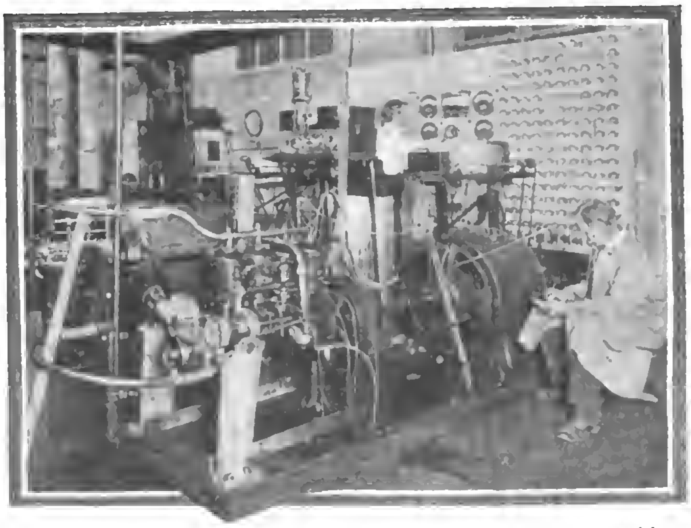

Fig. 5—Method of testing motors using a dynamo-electric machine and a bank of lamps

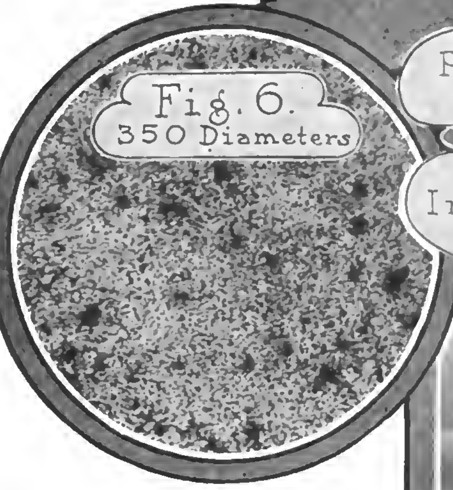

Fig 6.
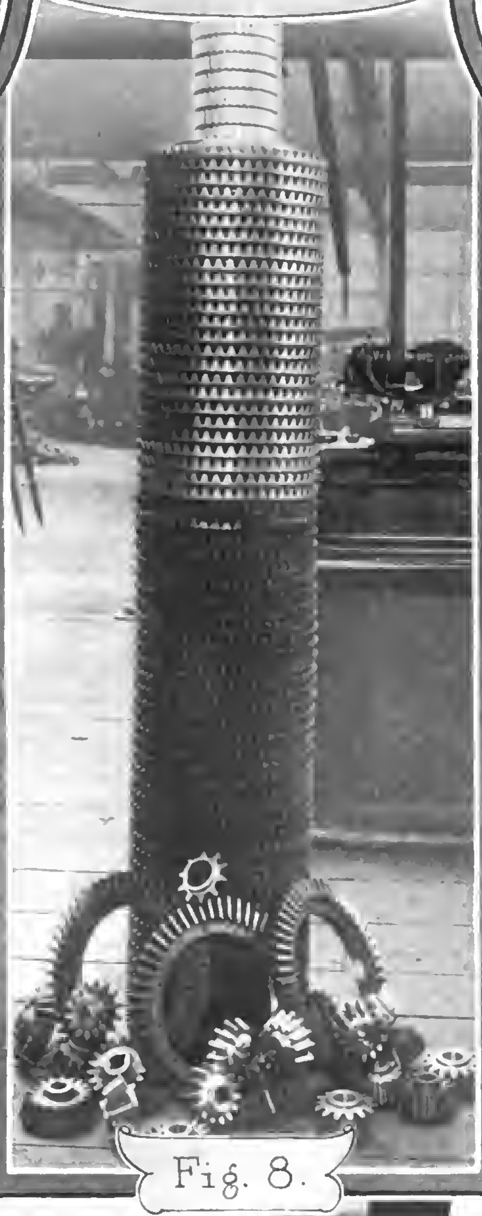
Properly Heat Treated Steel Magnified.

Fig 7.
Improperly Heat Treated Steel Magnified



greatest importance to properly record the tests, and in addition to charting, tabular records are taken and filed for reference. Just to indicate the extent to which this phase of the problem has to be dealt with, reference will be made to a brand of steel, noting its several qualities under the different conditions it will assume in the heat-treating process in response to changes in temperature, time, and methods of quenching. (See table.)

Material Encourages Further Effort—With a physical test such as this, assuming it is made during research, the next effort would be in the chemical laboratory, and the chemist after checking up results would make his declaration of constituents in tabular form, as the table shows.

The test proof, after fracture, would be examined with a critical eye, and a record would be made showing that the fracture is crystalline or silky, as the case may be, and if it is "cupped" this fact would be noted also; a further investigation of the material would probably be made to ascertain its dynamic character (kinetic ability) which might be done on a "Souther" type of testing machine as shown in Fig. 9; or, a Fremont test would show that even with a notched bar, under impact, a blow of 433 foot-pounds would have no visible effect. This is a marked result which was obtained for this grade of steel in the oil-tempered state, whereas the same steel in the state designated as tempered and annealed went under a blow of 144 foot-pounds in the Fremont test, and to indicate the effect of notching it is only necessary to point out that another sample of the same steel in the tempered and annealed state stood up to 361 foot-pounds. In order, however, to appreciate the significance of the comparison, it will be necessary to understand that ordinary grades of steel fall below these values by a considerable amount, as, for illustration, a rather good grade of nickel steel, of which a record is available, went at 36 foot-pounds in the Fremont test.

Microscope Lends Facility to Process—Even metallurgists have trouble in appreciating the differences in the conditions of the respective grades of steel as affected by heat treatment, and recourse is had to microscopic methods to bring up the structure and enable the investigator to determine with greater certainty as to the carbon condition and other molecular characteristics. The reader, in order that he may be in a better position to ap-

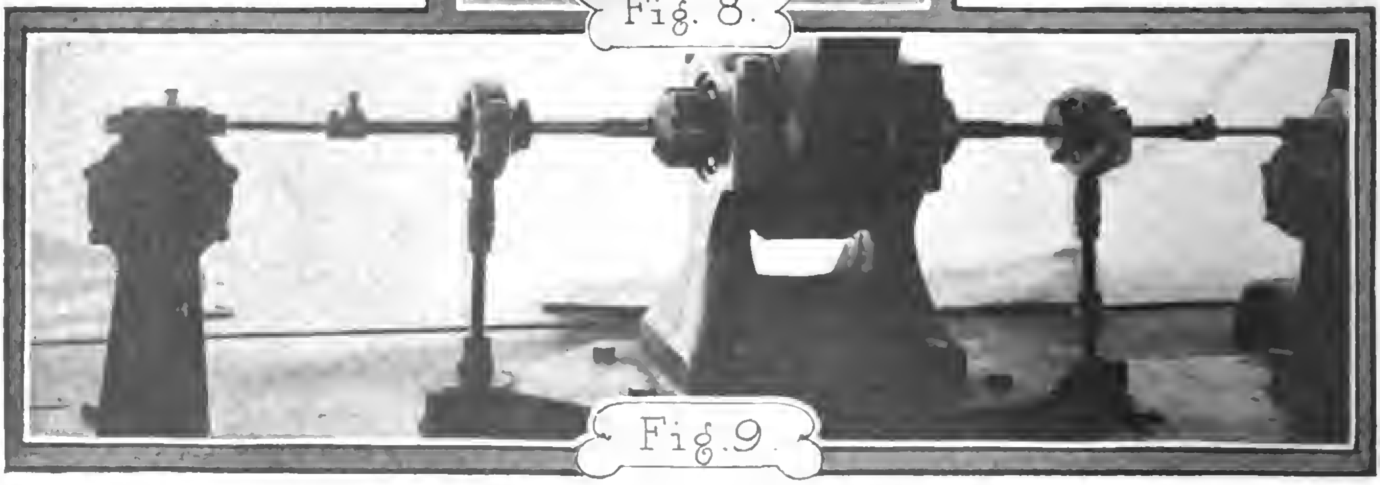


Fig. 8—Bevel gear cementing **Fig. 9—Determining kinetic properties of steel**

preciate the situation, is here offered micro-photographs of the steel that is being used as an illustration of the laboratory process, in which Fig. 6 represents a special and desirable condition brought about by heating, quenching, and tempering under well-regulated conditions; whereas Fig. 7 shows a specimen of the same steel which was injuriously treated. In the above examples the microscope was adjusted to 350 diameters, and for the purpose of determining the general character of the material this is about right. Modern microscopes enable the investigator to view the material even up to 1500 (or more) diameters, although it is not believed to be of great practical advantage to do so, as a rule.

VALUES OF THE MATERIAL UNDER CONSIDERATION.

Condition.	Tensile strength pounds per square inch.	Elastic limit in pounds per square inch.	Elongation per cent in 2 inches.	Reduction of area in per cent.
Normal	120,000	110,000	25	69
Tempered and annealed	160,000	145,000	12	49
Oil tempered	280,000	262,000	3	22

CHEMICAL COMPOSITION.

Chromium	1.60	Phosphorus	.011
Nickel	4.40	Manganese	.40
Carbon	.28	Arsenic	.006
Silicon	.20	Copper	.007
Sulphur	.010		

Diverse Forms of Furnaces Available—In the plant, owing to the wide use of drop-forgings and other parts from special grades of steel, it has been found necessary to employ a wide variety of equipment for the processes of heat-treating. Fig. 12 will serve as a suggestion of the methods used, in which, as the illustration indicates, it is very much up to the intelligence of the man; and the years of practice in the Jeffery plant have resulted in a corps of trained men, each one of whom is devoted to some one class of the work, so that if the company has for any reason to dispense with the services of some one man, it is an easy matter for Thomas B. Jeffery to step in, fill the breach, and coach an understudy.

Fig. 10 offers a better idea of the extent of the facilities, this being a view taken in one corner of the large heat-treating plant, where the parts are:

(A) Case-hardened
(B) Annealed
(C) Quenched in oil, water, or otherwise
(D) Tempered
(E) Special treatments.

The particular furnaces shown are for cementing (case-hardening), and, as will be observed, after the parts are packed in bone (which is a matter of employing a suitable box, proper grades of bone or other cementing materials, and much care in the process of packing) they are then run into the furnace, and heat is applied for a sufficiently long time to grow the required depth of carbon. The time required is dependent upon several conditions, as shape and weight of parts, grade of steel used, temperature of the furnace, quality of the bone or other cementing material, and such matters. A means is at hand for regulating the temperature, but what is more to the point, pyrometers are available by means of which the temperature is made known to the men who do the work.

Certain Parts Draw Skill to the Maximum—Bevel gears, as depicted in Fig. 8, after they are shaped, must be hardened, and as is well known, they are very prone to warp in the process of hardening. In order to avoid this, since the gears have to be rejected if they warp, they are drop-forged, annealed after each operation, turned up to size, then annealed again, and, after being given every possible attention, are shaped (the teeth are fashioned) in which process the teeth are first "gashed" and finally "sized" in a Gleason planer.

The steel is of a cementing character, and in the process of cementation the utmost care is exercised to avoid over-heating, wide variations, or other changes, such as will tend to accentuate warping during quenching. When the gears are hardened, they are then subjected to a grinding process to bring the bolting (flange) faces true; and the final inspection measurements, by means of instruments of precision made in the Jeffery plant, soon tell the inspector what to do with the gears; if they come true, they are advanced to stock; if they do not, they must be placed in a bin of rejected parts until they can be examined by Thomas B. Jeffery, who reserves for himself the task of determining why the parts fail to respond properly to the process.

Fig. 10—Battery of cementing furnaces, one of which is receiving work, depicting method of handling

Testing Is Intermingled with Machining—From what has been said it is self-evident that enforced co-operation is essential to the success of the venture; each part, as it is being made, must be inspected a number of times, may have to be annealed more than once, and it is of the greatest importance to follow up the work and ascertain if the treatments are being made with precision. In order that the work may be properly done within a reasonable figure of cost, it is necessary to provide ample means of transportation in the shop, and Fig. 11 is offered to show what is done to satisfy this end of the situation, it being the case that "industrial railway equipment," as shown, is provided at every point, which equipment is supplemented by an overhead system as in common use in abbatoirs, for the purpose of transferring completed motors to the laboratory and thence to the assembling department after they are tested.

Power Plant Given Greatest Care—From the hydrostatic test of each cylinder, as presented in Fig. 3 (which settles as to the strength and tightness of the cylinders) to the motor assembled, are all routine matters under the control of the regular force, but once a motor is lifted off the assembling stand by means of the traveler, it is in the hands of the responsible head of the testing laboratory, and from that time on it is regarded in the light of an individual power plant rather than as one of many motors, and individuality is injected into its makeup.

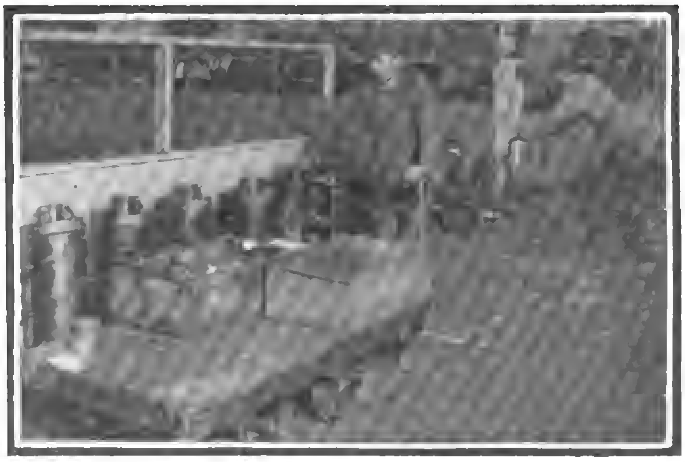

Fig. 11—Industrial railway system used in the plant for forwarding materials, showing use of tote pans

Fig. 12—Portion of heat treating department, with furnaces, quenching baths, and other facilities in actual service

Prior to the completion of the present laboratory, the method of testing motors was not very different from that which obtains in general practice, in which an electric generator is driven by motor to be tested, substantially as shown in Fig. 5. In this work, the motor drives the generator, and the output of the generator is delivered to the lamp-bank with instruments in the circuit, by means of which the voltage, current, and wattage of the generator may be determined, from which the power delivered by the motor may be calculated.

Present Method a Great Advance—In the new laboratory, rather than to labor under the disadvantages which attend the older methods of testing one motor at a time, which as a rule results in some of the motors being slighted, a considerable number of motors are placed on stands as shown in Fig. 12, in which the motor to be tested in each case is placed in the cradle, which is so designed that the motor arms fit readily. Each dynamotor is capable of absorbing power as a dynamotor, or, by suitable manipulation, it may be induced to deliver power to drive the motor undergoing test. The dynamotors are shunt-wound, separately excited, and so connected to the control board that the tester is enabled to regulate the whole situation in a definite way. If there are, say, 30 motors undergoing test at one time, one-half of them will be delivering electrical energy to the other half, it being the case that one-half of the dynamotors will be operating as generators, supplying electrical energy to the other half as electrical motors.

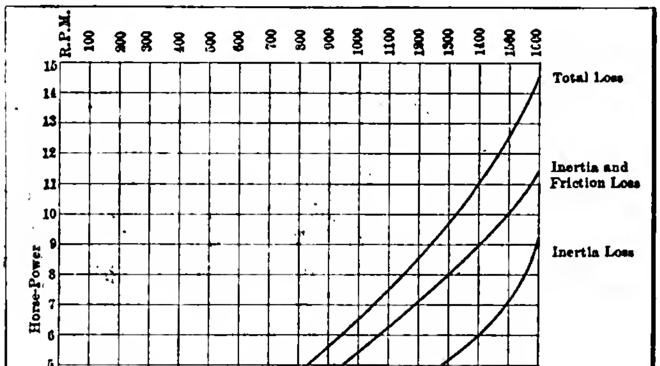

Fig. 13—Curve plotted to represent pumping losses in gasoline motors and subdivisions

If an odd number of motors are being tested, it is obvious that there will be a slightly unbalanced condition, and this difficulty is coped with in an advantageous way; the unbalanced increment is regulated to deliver electrical energy which is transmitted to storage batteries, and they are thus charged. The storage batteries are ultimately employed in the ignition system of the automobiles delivered from the plant, and since they are delivered in the green state by the makers, they are in the best possible condition from a practical point of view.

At regulated periods during the day, the tester shifts the motors that are being driven to a driving relation, and the motors that were driving are thrown to the driven relation long enough to determine the amount of energy required to drive them before they are removed from the stands. In thus ascertaining the power required to drive each motor when it is running at its maximum speed, it is possible to determine as to its mechanical condition, and if the bearings are not in good working order this fact will be rendered at once apparent.

Each Motor Is Put to the Test—As the tester discovers by means of electrical instruments and other equipment that a motor is approaching its proper form, it is selected out and made the subject for special (individual) investigation in which the "Purdy" manograph plays an important part when the occasion requires. Before attaching the manograph, however, the bearings are properly run in, it being the case during testing that lubricant is supplied by adding a certain proportion of lubricating oil to the gasoline. Then the temperature of the cooling water is adjusted to a standard, 180 degrees with a raise of six degrees (Fahrenheit) being about right for the best results.

With the motor in good order, cooling at the right point, and lubrication on a standard basis, it remains to plot a curve of speed and torque, which may read speed and horsepower, as shown in Figure 4, which is of model 44 and 45. In this chart, as an inspection will disclose, the ordinates read speed in revolutions per minute of the crankshafts, and abscissa read horsepower. As a convenience and for purposes of comparison, the curve may show equivalents, as miles per hour of the car on the road; as for illustration, taking data afforded at 1,500 revolutions per minute of the crankshaft of the Model 44 motor, the power shown is 34-horsepower and the gear ratio being as 14:52, the car should make 43 3-4 miles per hour on the road; by means of other curves, it will be possible to determine as to the competence of the relations, and if the gear ratio is not right, or if the motor is not up to power, these facts will be disclosed.

Analysis of the Motor Made—It has always been easy enough to discover if a motor were below power, but it is quite another matter to analyze the same and locate the particular difficulty which is at the bottom of the trouble. Fig. 13 is a chart giving the results of just such an investigation, dividing in such a way as to bring out the points to be made, rather with the expectation that they may be brought into greater harmony, possibly, by reducing some of them, and, in some instances, by trading off; that is to say, actually increasing some of the losses, hoping, perchance, that others will fall off at a greater ratio, and, on the whole, make a gain. The losses, as presented in the chart, are subdivided as follows:

(A) Total loss;
(B) Inertia and friction losses;
(C) Inertia loss;
(D) Friction loss:
(E) Valve loss.

In this chart the ordinates read miles-per-hour of the car, which for that matter might be reduced to revolutions per minute of the motor, as is shown at the top, and abscissa read horsepower losses. It is interesting to note that:

(A) The total loss increases at an alarming rate at the higher speeds, which condition is to a large extent due to the influence of inertia (C), and valve losses (E).

(B) Inertia and friction losses curve up at a less rapid rate with increasing speed, due to the fact that the friction losses do not increase at such a rapid rate as the speed increases.

(C) Inertia, which is the bane of motors, increases as the square of the speed, and it is this class of losses that are most difficult to determine, either in designing or in testing motors.

(D) Friction loss, as the curve indicates, is in direct proportion to speed.

(E) Valve losses increase very rapidly at the higher speeds, and must be a serious factor in poorly designed products.

This particular chart is not offered as absolute evidence of characteristic losses of the several genera in motors in general, it being the case that time and many tests will best establish the characteristic. It is by way of a considerable advance in motor building, however, that this form of analysis is offered.

From what is now known, as a result of investigations, conducted under the new conditions, a positive gain, of considerable magnitude, will be experienced in the motors which will have the benefit of the laboratory method of testing the regular Rambler output in future.

Popping Not Due to Weak Mixture—Among the discoveries made in the laboratory, for illustration, is the fact that popping back into the carbureter is not possible when the manifold is properly designed. In order to prove this, a sparkplug was placed in the carbureter manifold and was connected up to the sparking system in such a way that the mixture in the same was ignited just as the inlet valve opened, or slightly before. The mixture was then made rich, and verged down to weak, with the result that popping did not take place at all when the regular Rambler intake manifold was used.

When a special, large area, manifold was substituted, popping invariably transpired, which went to prove that when the rate of speed of the mixture in the manifold fell below the rate of flame-travel in the body of the mixture, the flame traveled back to the carbureter, thus inducing the phenomenon called popping. This same test proved that there is something to be considered involving the length of the manifold; if it is too short, considering inertia, and certain other conditions, overlaping, in setting the valves, may lead to complications and popping in the carbureter.

As a result of the investigations which were made under the new conditions it was possible to alter the curve of torque of the motors, over broad ranges, differing widely from the curves as shown in Fig. 4, and it will be proper here to state that these curves are not, now, fully representative of the results attained, it being the case that the motors, in giving them what is termed individuality, are so tuned up that they will fit well, under the conditions determined by service to be rendered, taking into account the gear ratio, weight of the car, general character of the geographical locality in which they will be required to operate, etc.

The evidence, thus far offered, while it is but a small part of the Rambler practice, is sufficient to show that under proper supervision in a shop properly equipped for the purpose, laboratory methods can be applied to every motor turned out. In order, however, to be able to determine if the cars as a whole are up to a fitting standard, it is necessary to try them out on specific grades under fixed road conditions, and for this purpose the company has, on its own grounds, a grade, designed for the purpose, evidence of which is offered in Fig. 14. Besides this grade, which as the illustration shows, offers the facility of 20, 30 and 40 per cent. inclinations, the circular track to the rear of the plant on the company's own ground makes it possible to put the finishing touches on Rambler cars, and individuality is clinched.

Fig. 14—Special grade constructed to try out Rambler automobiles before delivery affording great advantage

TECHNICAL FEATURES OF THE NATIONAL CAR

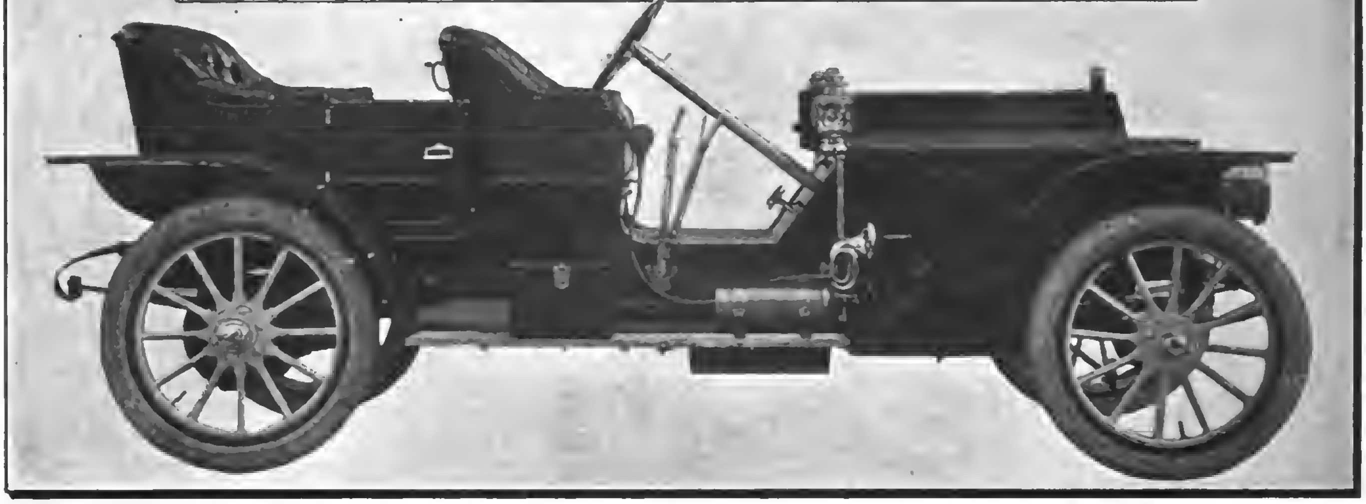

Fig. 1—Four-passenger toy tonneau with roomy driver's seat, ample foot room, large steering wheel, and excellence of control

REFERRING to Model 40, the general appearance of which is well set off in the title illustration, it will be the purpose here to delve into the details of design and construction, without clouding the issue by referring to the general and commercial characteristics of the car. All figures, excepting the title half-tone (Fig. 1), were reproduced directly from working drawings, and the actual product was examined closely by the author at the works of the National Motor Vehicle Company at Indianapolis, Ind., thus checking the drawings with the finished product, it being the idea to present verified facts in technical work of this character.

Referring to Fig. 2 of the chassis, M1 is the motor, C1 is the clutch, C2 is the coupling, T1 is the transmission, U1 is the universal joint, just back of the transmission, secured to the propeller shaft, is within the tube T2, which extends back to the live rear axle housing H1, with the cover off, disclosing the bevel pinion P1, meshing with the bevel gear G1, which gear is flanged and bolted to the differential housing H2, and within the differential gears are nested.

The two differential shafts D1 and D2 take the differential gears and, following out D1, it passes to the left rear wheel, engaging in concentric relation Timken roller bearings B1 and B2, thence passing out to the jaw drive J1, thus disclosing the manner in which the live rear axle is designed as a floating type.

The brake drum B3 is of large diameter, has an outside constricting band, B4, and an inside expanding band B5. The outside band is manipulated by the shaft S1, while the inside member is controlled by the shaft S2. Turnbuckles T3 and T4 provide for adjustment and an equalizing member E1 assures that pressure will be constant on all shoes. Turnbuckles T5 and T6 are placed to afford additional means of adjusting the brakes so that the right tension may be induced.

Steering Equipment Is of the Straight-Line Design—Referring to the cross-rod C3, it passes to the rear of the front axle, being straight, and yoked to the arms A1 and A2 by strong drop-forged yokes Y1 and Y2, with large bearing surfaces. The drag rod D3 is straight, has a spring buffer in the terminal piece T7, while the front end of the rod engages by means of a ball and socket of liberal proportions B6 to a boomerang-like arm B7, which in turn is secured to the front knuckle K1 on the right side of the car. For the rest in view of the clearness of the drawing, the design is obvious and this part of the subject will therefore be stopped off, with the single exception that attention is called to the shape and strength of the side-bars of the chassis frame, also to the neat manner in which the cross-bars are joined.

Important Details of Live Rear Axle—Referring to Fig. 3, of the live rear axle and propeller shaft up to the point of joining to the transmission gear through the universal joint J1, the

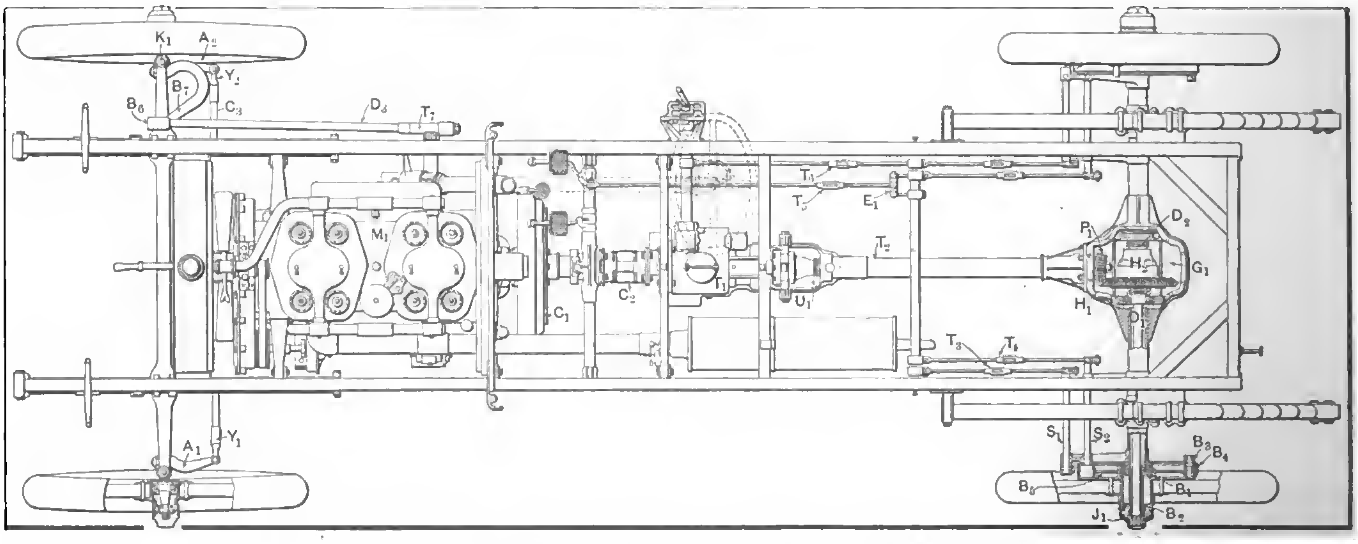

Fig. 2—Plan of Model 40 chassis with units in correct relation, showing nice features in design

propeller shaft P1 turns in Timken roller bearings B1 and B2, is of liberal diameter, being of a selected grade of steel, and is inclosed in a stout tube, T1, which telescopes with terminal forgings F1 and F2. The forging F2 is threaded for the tube T1, thus allowing for proper adjustment of the taper roller bearings B1 and B2, in which the washer W1 serves as an abutment.

Within the shell of the live rear axle, as it looks with the cover off in Fig. 3, the bearing housings H1 and H2 are provided with caps, as shown, and adjustment is made by means of the nuts N1 and N2, with lock-nuts N3 and N4 to prevent them from backing off. The spring perches, one of which is shown at P2, are free to rotate on the shaft-tube, so that the springs, which are two inches wide, do not have to take torsional load, in being handled by the tube T1 exclusively.

Most Noteworthy Details of the Motor—Experience has taught that, no matter how good a motor may be or of what the materials may consist, lubrication is at once assurance and insurance; assurance that the motor will not become an immediate source of trouble on the road if it will run at all, and insurance of a minimum of depreciation.

The table of motor torque shows the ability of the same, the dimensions of which are as follows: Bore, 5 inches; stroke, 5 11-16 inches; it being of the four-cylinder type, with water cooling, working four-cycle in the conventional way, the most important point being that the valves are relatively large and the compression is adjusted to match.

The method of testing is that of the electro-dynamometer and, as the test record states, calibration for internal losses was cared for, hence the final readings for horsepower are to be relied upon. The horsepower readings at the several speeds are such as to indicate that the "pumping losses" are well within bounds, which is indicated when the power is noted to be 47.68-horsepower at 900 revolutions, and by doubling the speed the power, instead of falling off at an alarming rate, is steady at 80 horsepower. As the test further indicates, the limit of power is not reached even at 1,800 revolutions per minute, although in practice it is scarcely to be expected that the motor will be required to work at this higher speed, unless in racing on tracks of quality, as the Speedway at Indianapolis, advantage might be taken of this higher speed.

How the Lubricating Problem Is Coped With—By referring to Fig. 4, which is a section of the crankcase, longitudinal at A and cross-sectioned at B, it will be observed that the lubricating oil is held in a basin, B1, which in section looks as in B2. In the same sectional view the filter F1 is placed, and the arrows show that the oil flows in, it being cleaned at this point. The crankcase is scooped out, or, better yet, it is contrived with a false bottom, B3, with well-holes, W1 and W2, leading into a passageway, P1, connecting the two, and at the mid-position of this passageway a third well-hole, W3, is placed, the purpose being to equalize the flow of oil, preventing it from piling up when the car is negotiating a grade, and in this way the cylinders are prevented from becoming fouled.

Referring to the cross-section B, Fig. 4 again, the oil-pump P2

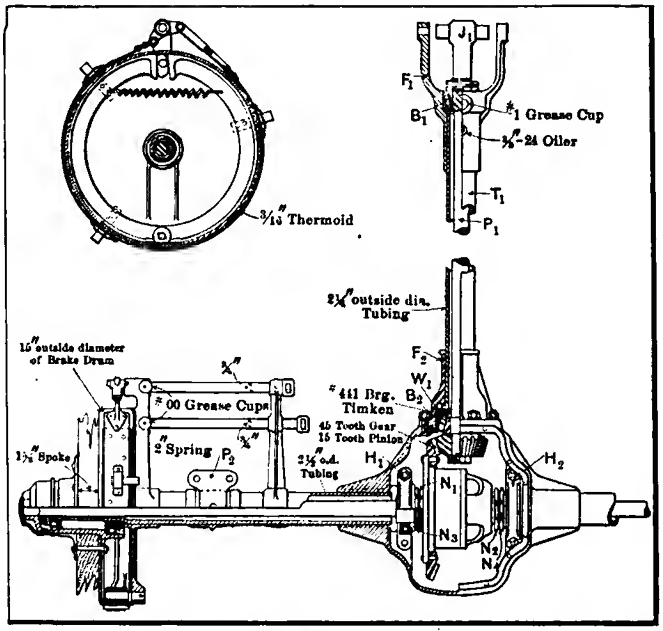

Fig. 3—Live rear axle, showing torsion tube, propeller shaft, bevel drive and floating system

is located in the bottom part, is driven by the vertical shaft S1 and Oldham coupling, O1, prevents the shaft from being cramped and allows the gear-pump entire freedom, so that the members are free in the housing.

A telltale pipe, P3, leads up to the telltale T1, which enables the operator to note if the pump is working and if oil is present in sufficient quantity to serve the purpose. The return pipe P4 takes the oil away from the telltale so fast that the glass does not cloud up. From the return telltale pipe P4 the oil leads through the passageway P5 and thence on to the respective points to be lubricated, as L1, L2, L3, and L4, for the main bearings of the crankshaft, as shown in the view A, Fig. 4. The crankpins are lubricated by a splash as at P6, and oil passes out to the herring-bone half-time gears, as at G1, while other remaining surfaces receive such profuse lubrication that the whole system works in harmony. In addition to the special means of lubricating, as here presented, grease cups are placed at all points of vantage, the idea being to keep out the silt of the road, and maintain noiselessness for the greatest possible length of time, as measured in years. It is generally well understood that noise will creep into a car in a short time if the joints wear, and they will if they are permitted to go dry. Grease cups then, in addition to the regular lubricating system, assure life and absence of noise.

The bearings at every point are long, the projected area is liberal, and the working pressure is such that there should be no trouble, even were the lubricating problem less carefully cared for. It is a noteworthy point that the oil cannot sneak out, nor

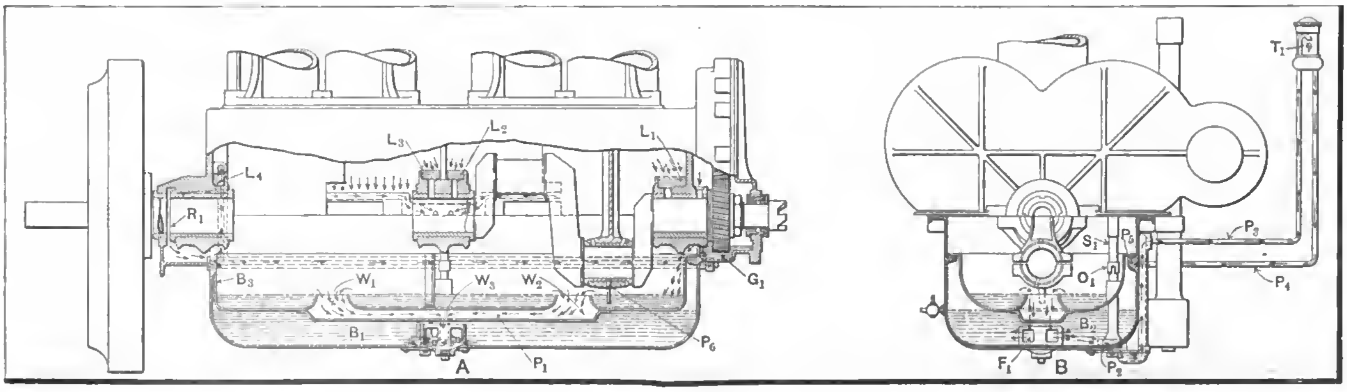

Fig. 4—Sections of crankcase offering evidence of a well-designed lubricating system

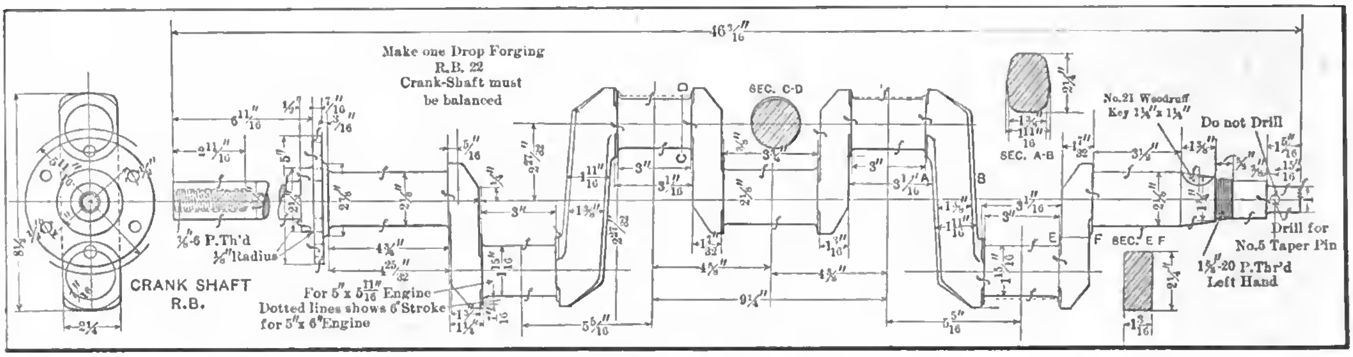

Fig. 5—Crankshaft, with flange for flywheel, substantial cheaks, liberal bearings and good material

can silt of the road migrate in; this point will be sufficiently illustrated by glancing at R1 of the bearing next the flywheel; the arrows indicate how the oil returns back to the point from whence it came.

TEST OF MODEL 40 MOTOR.

R.P.M.	Amp.	Volts.	Watts.	Eff.	H.P.
1,800	162	295	47,800	.800	80.00
1,600	152	285	43,350	.813	71.50

700	148	154	22,792	.852	35.64

A Substantial Crankshaft Presides—The dimensions of the crankshaft are given in Fig. 5, showing symmetry in design, a flanged flywheel, rigid throws, and a condition of excellent balance. The material is crankshaft steel of a selected grade, it being heat-treated to accentuate kinetic qualities. The setting for the crankshaft is best shown in the section of the motor as given in Fig. 6, and in the same section will be found divers features of design which have proven out, among which the timer T1 is up above the cylinders, where it can be gotten at.

The valves V1, being 2⅞ inches in diameter, have inserted guides G1 and means of adjustment J1, which stay put. The camshaft C1 is of special hardened steel and the cams, one of which is shown at C2, are cut integral, care being taken to have them accurately ground to size. The arms, which reach to the sidebars of the chassis, are bolted onto the aluminum housing of the motor, and rigidity is thus joined with a certainty of the quality of material, on which dependence must be placed for the hanging of the motor. At the front end the starting crank S1 is held in disengagement by the spring S2, and the engaging jaws J2 and J3 are supported in good form by an extension, E1, of the motor case, with an outboard bearing, at which point a grease cup is located.

The water jacket around the combustion chamber W1 is commodious, and especial attention is called to the absence of a plug in the cylinder head H1, but a column is there and a priming cock, P1, is provided for, a hole being drilled in the column for the purpose. The pistons P2 are light, made of a fine grade of gray iron, and are strongly ribbed. The piston pin P3 is prevented from floating out by the capscrew S3 and four piston rings, R1, R2, R3, and R4, assure tightness.

The fan F1 is of substantial design, runs in annular ball bearings B2 and B3, and is rigidly supported by the pedestal P4 to the motor case. The water piping P5 is of liberal diameter, well made, and joined to the cylinders by fittings F2, which are at once neat and lasting.

Cone Clutch of Great Simplicity—Fig. 7 is a section of the cone clutch with a leather facing, L1, and flat springs are placed under the leather around the periphery for the purpose of pressing the leather into proper engagement. The clutch is flanged, F1, and a long bearing, B1, serves to maintain concentric relations. The square spring S1 presses the clutch into engagement, and adjustment is secured by pressing the thrust block of the ball type up against the other end of the spring. Thrust is equalized by means of the ball thrust-block T1, and the universal joint back of the clutch J1 occupies a dual capacity, in that it compensates for flexure and takes up endwise motion.

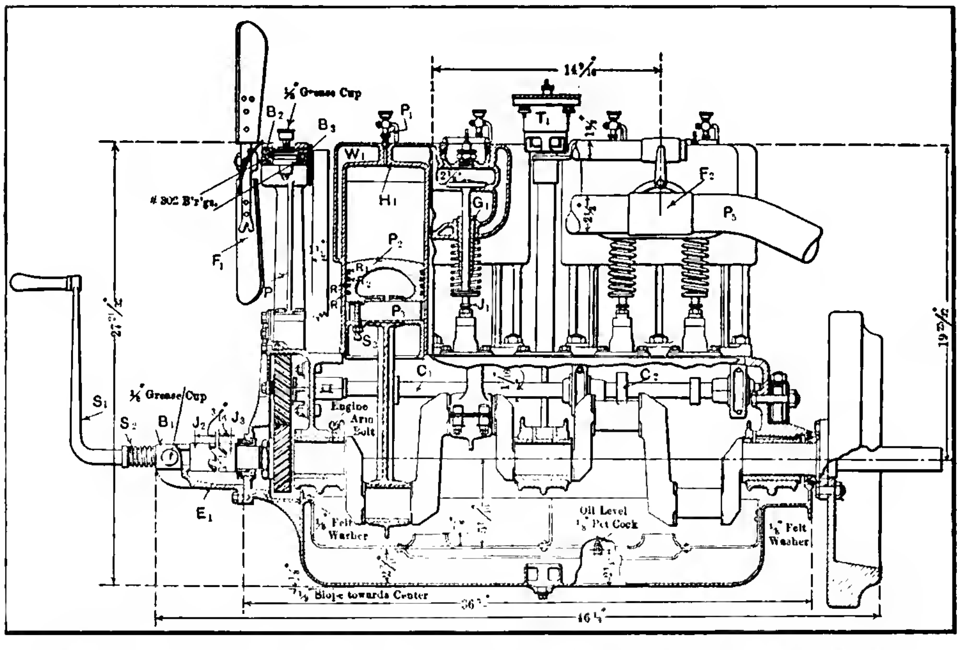

Fig. 6—Motor in section to present evidences of power at all speeds, using large valves, etc.

Of the many remaining features, they will have to be shown rather than discussed, and Fig. 8, which is a side elevation of the chassis, will suffice for the purpose. The transmission, for illustration, is a three-speed and reverse selective, with the lay shaft below as shown at T1, in which annular type ball bearings are at every point. The drive is straight line, and dust preventers D1, together with grease cups at every point of vantage, makes for long life and noiselessness.

The rear springs are three-quarter elliptical scroll type, with numerous wide, thin, flat plates rather than a smaller thick plate, the idea being to absorb shock without inducing excess strain in the material of the springs. At the front end, in view of a substantially constant load, the springs are half elliptic, but the plates are wide, thin and retained. The radiator is situated back of the centre of the front axle, which augurs for easy riding, and the general appearance of the car is pleasing, partially on this account, and for numerous other reasons besides.

The I-section front axle is of the most approved shape, and with 36-inch diameter of tires, in view of lightness of the car as a whole, the cost of maintenance should prove as agreeable as the riding qualities are said to be.

Notable Features of the Accessories—The water pump, which is of the centrifugal type, of liberal capacity, and designed for long life, is located on the right side of the motor, above the top of the chassis frame, hence accessible, and is driven by an Oldham jointed on a stub-end, which projects out of the pump casing, on a line with a stub-end of the gearshaft, projecting out from the housing, which covers the train of gears, of which the half-time gear system is a part.

The pump is placed on a ledge of the crankcase, and it being flexibly connected to its drive, there is no question of lineing up to be coped with. The pump shaft, where it extends through to the back, is utilized to drive the magneto, but in order to maintain the scheme of flexibility, and overcome trouble in lining up the accessories, a double universal joint is intervened, so that the magneto is also above the chassis frame so far as accessibility is concerned, and being flexibly connected, it may be removed, and replaced, at a moment's notice.

The magneto, which is a Bosch, works in conjunction with a coil, and a storage battery which is the source of the auxiliary electrical energy used in the coil. The wiring is very neatly and securely placed, tubing being used to house the same, and the timer, being at the middle of the motor, is in a very satisfactory location from the point of view of accessibility, and haphazard wiring arrangements are eliminated.

Double Universal Joint in Transmission—Flexibility, while it is being discussed in connection with the placing of the accessories, may as well be mentioned in general, it being the case that a double universal joint, of very substantial characteristics, is located in the system, just in front of the transmission gear, the virtue of which is manifold. This dual universal joint in front of the transmission gear is in addition to the universal connection of the propeller-shaft tube. The mere use of a very substantial chassis frame, in this car, is not construed as sufficient, and the whole machinery equipment is so placed, considering flexure, that none of the elements will be pinched, under any circumstances, and noiseless performance, to a marked degree, is realized, partly due to the shapes used, and again, due to the close fitting which is allowable.

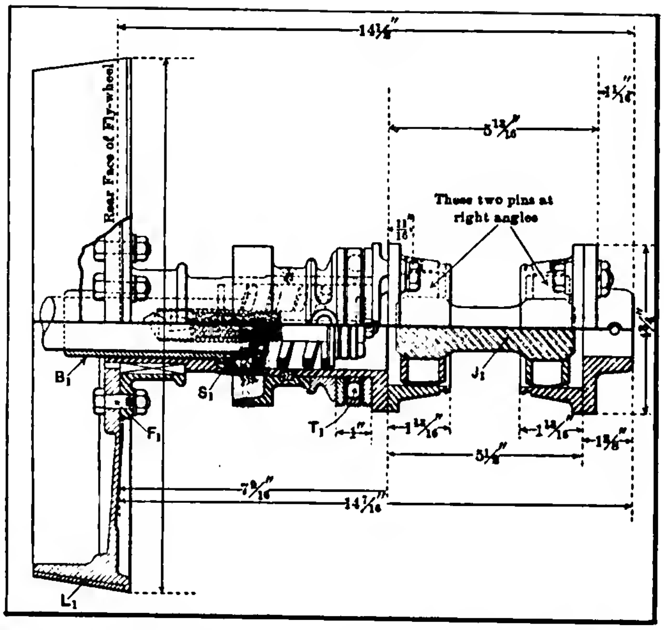

Fig. 7—Section of clutch, of the cone type, with square spring, leather facing, and ball thrust bearings

Radiator and Water Piping Well Placed—The radiator, of liberal capacity to wipe heat out of the cooling water, is placed just back of the front axle, thus adding materially to the general appearance of the car, and the water piping, which is neatly made, is flexibly joined, yet even so, this flexibility is not at the expense of quality, since the hose joints, as made, do not include long lengths of hose. The piping, where joints are made, is so closely jointed that almost no hose is exposed to the action of Winter's cooling solutions, which latter products are usually so made up as to destroy the hose. In testing out, every car is afforded enough individual attention to impart to it a certain precision of performance, it being the aim of the maker to earn a reputation for uniformity, in performance, of every car made. The chief tester, with good facilities, is enabled to try out every car, after the regular (routine) testing is completed, thus checking the regular tests, with a view to safety.

Perhaps the neatness of the mudguards, aprons, and trim in general is worth praising, as a rule; however, in a car of this quality, such details are, as a matter of course, right. Then, the shape, and finish of the mahogany dash is worthy of notice, and the equipment in general, as lamps, tools, etc., are on a sufficiently high plane to match up with the rest of the car.

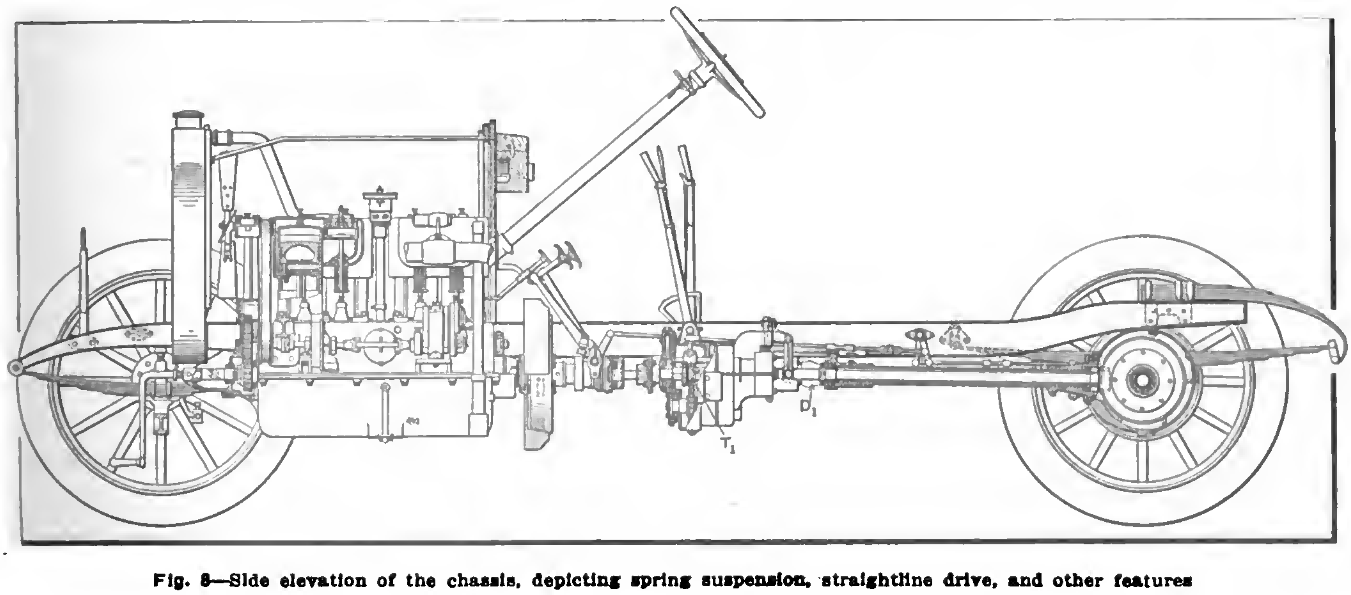

Fig. 8—Side elevation of the chassis, depicting spring suspension, straightline drive, and other features

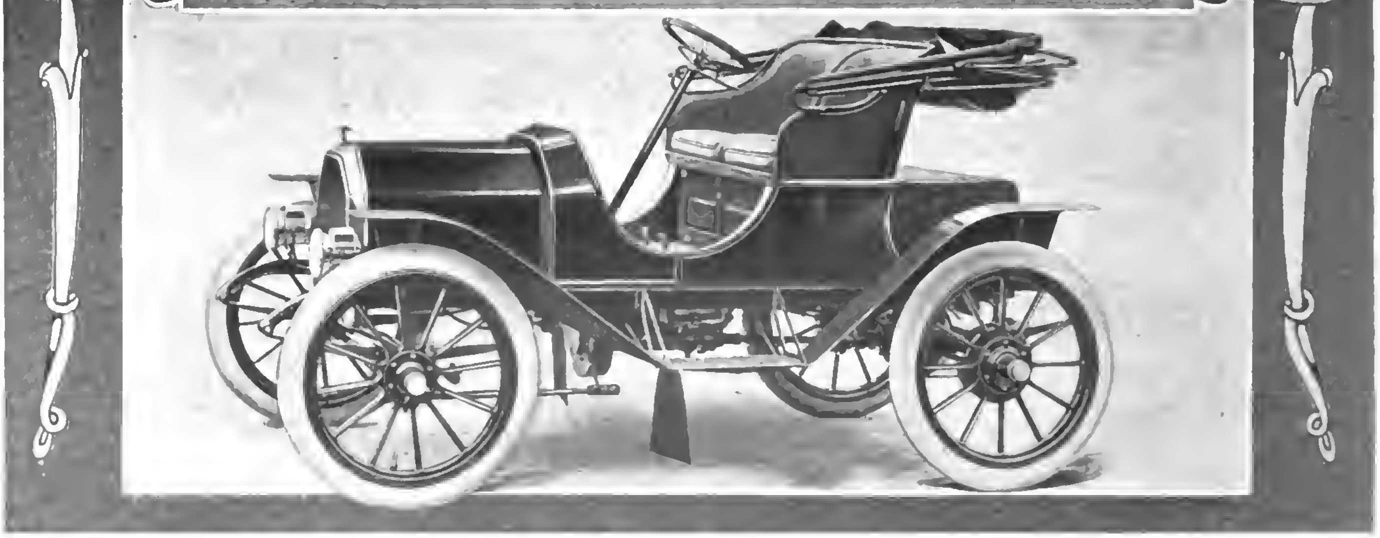
1910 BAKER ELECTRICS ARE SHAFT DRIVEN



Baker Electric Runabout Has Wheel Steering, Bonnet in Front, and Closely Resembles Smart Gasoline Runabout.

IN CHANGING from chain to shaft drive, for use on electric cars, the Baker Motor Vehicle Company, Cleveland, has taken a most radical step, and one that will be commended by all who have followed the progress of the two drives on gasoline-driven cars. In that field, the shaft has supplanted the chain, for obvious reasons of cleanliness, simplicity, protection against dirt and consequently wear, absence of lost motion, and improved lubrication.

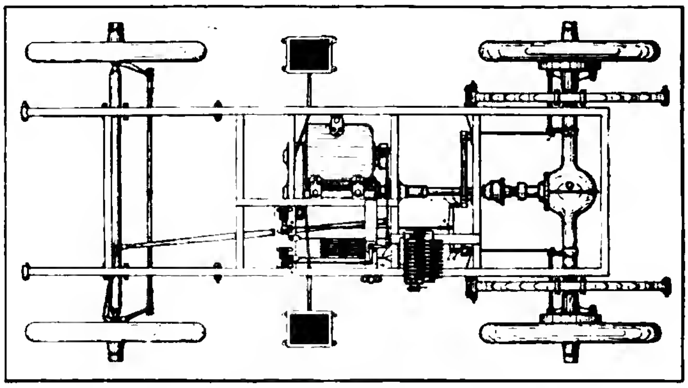
Arguing forward from this, the electric manufacturers have said, why does not the same line of reasoning apply to our class of vehicles? In adopting it for all vehicles, the Baker company has taken the stand that it does, at least, to their complete satisfaction. This step will cause much comment in the industry, for this concern has always been a leader, and if the other companies follow this lead, it means the extinction of the chain for all but commercial trucks.

Bevel Gear Tried First on Large Cars with Success—The company has used the bevel gear with perfect success on larger types of cars, but has only succeeded after many years of experimenting in perfecting an improved bevel-gear shaft drive, which is suitable for small cars, and which at the same time excels in efficiency all other forms of transmission.

It has been found by experience, the officers of the company say, that the chain drive loses its efficiency on account of its imperfect lubrication, accumulation of dust and stretching of the chain; they claim that the new bevel-gear shaft drive will maintain and even increase the efficiency of the car.

The bevel drive, rear axle is of the semi-floating type of the very latest design, approved by the best engineers. To secure lightness and greater strength, the entire rear-axle housing is drawn from sheet steel. All the bearings in this axe are of the ball-bearing type of the highest quality. The axle and drive shafts are made from vanadium alloy steel, carefully heat treated.

Special describes the differential, with which, all of the gears in the rear-axle housing, including the differentiating gears, are made from the highest-grade steel, specially obtained for this purpose. They have planed teeth and are hardened by a special process. The differentiating gears are mounted on a three-arm



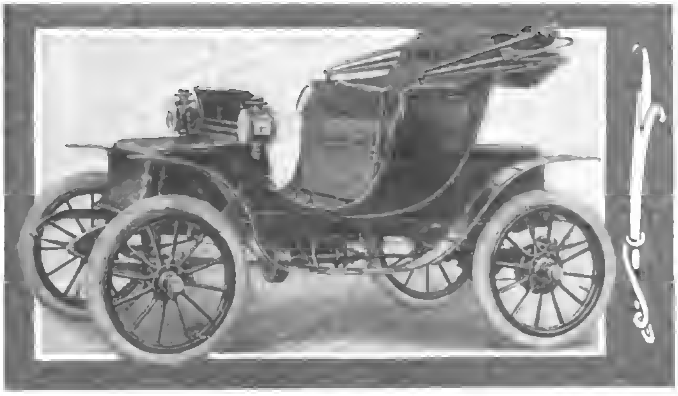
Chassis of All 1910 Baker Electric Cars Are Alike.

member and careful provision is made for a self-aligning movement of these gears. The fit for all bearings is provided by grinding to limit gauges, and maintained within limits of .00025 in.

Sheet steel is the material of the front hubs. This is drawn out from the flat sheets in presses to form it to the correct shape. The resulting hub is in one piece, and consequently, stronger. These hub pressings are accurately machined and are fitted with ball bearings of the best quality. The front axle spring seats are machined from a high-grade steel and the tube is of special semi-spring temper steel with dropforged yokes attached to the tubing by the electric welding process.

Renold Silent Chain Drive from Motor—A Renold silent chain (provided with an eccentric adjustment) enclosed in an oil and dust-proof case is used on the reduction gear, insuring silence, flexibility and high efficiency.

The transmission shaft is constructed with two universal joints of the latest approved design, allowing absolutely free action of the rear springs. One of these is located just in front of the rear axle, while the other is away forward, at the extreme front end of the driving shaft, and close to the motor. In this way, the full benefit is gained of the double universals.



Victoria Is Along Regular, Approved Electric Lines.

The front ends of the full elliptic rear springs are suspended from the frame by a novel shackle (patent applied for) which is an entirely new feature in spring suspension. This construction permits the omission of the radius rods and the torsion rod, assures perfect alignment under all conditions with a maximum of safety, and eliminates absolutely the rattle so objectionable with radius rods. All springs are of the special spring steel and are provided with reamed bronze bushings. All spring bolts are made from alloy steel, ground to size and are provided with special attachment for oiling.

Salient and Valuable Motor Features—The motor is of a special four-pole design, series wound, with unusually large commutator. It is larger than motors ordinarily used and possesses an electrical characteristic which makes it almost impossible to injure and insures continuous service with the highest possible efficiency, without requiring any attention whatever. This accounts in part for the long life of the batteries in Baker cars.

Three-point suspension is used in hanging the motor in place, one arm at the right side and two at the left holding it securely, yet so as to be readily and quickly removed. These supporting arms are bolted to the subframe built in for that purpose.

The latter, that is the frame, is of pressed steel, channel section, with the open side turned in. There are five cross members, one at the front end, and the usual rear stiffener. Then there is one at the line of centers of the front spring hangers of the rear springs. The other two are placed one on each side of the motor, with the subframe connecting the two.

What the Controller Shows—The patented controller is of the continuous torque drum type with six speeds forward and three in the reverse, all controlled by one lever. No special pedals or switches are used. This controller permits the various speed changes without arcing or fusing, and accomplishes a gradual increase of speed from step to step with a small increase of current consumption, and without any jerking motion, either in starting or increasing speed. It is also provided with a safety device which precludes the possibility of slipping into the reverse when shutting off power.

Another feature of the new models is the special lock (patent pending) for the controller. This device is extremely simple and is independent from any electrical connection, being purely mechanical and of absolute reliability.

Other Car and Equipment Details Worth Knowing—Wheelbase on the new models has been increased to 80 in. by moving

Baker Coupe for Cold Weather Is Inside Driven

the front axle forward farther than in the old models and extending the frame. This makes the cars ride more easily.

Bodies of the 1910 models are more roomy, more comfortable and unsurpassed for elegance, style and beauty of design. All cars are equipped with continuous fenders.

Standard battery equipment for victorias and coupés has been increased from twenty-four cells to twenty-eight cells 9 MV Exide, in series at all speeds.

All new-model cars are equipped with three brakes, two internal expanding brakes attached to the rear wheels which are lined with thermoid, insuring long life and absolute reliability, and an emergency brake attached to the motor. All brakes are operated by steel rods, the expanding brakes on the rear wheels being controlled by one pedal with an equalizing bar inserted, which secures equal pressure on both brakes.

Special care has been taken in wiring. The wire sizes are abundantly large to carry the heaviest possible loads without loss of power directly from the battery to the controller and from there to the motor. All mechanical connections are tight and securely locked. The entire wiring system is mechanically arranged and the wires are insulated to resist acid and weather, as well as mechanical strain, the best rubber being selected as none too good considering the work to be done.

ELECTRIC THAT MADE GOOD ON THE MUNSEY TOUR

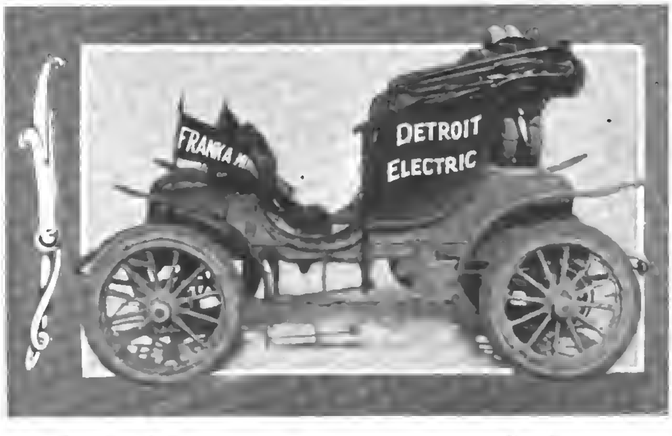
ORDINARILY, when reference is had to gasoline automobiles, it would scarcely be considered of moment to note the performance of any one example merely because the car may have mad a long run. Thre are so many people, however, who have the wrong impression about electrics that to fail to feature an electric which did come through the Munsey run on time would show lack of appreciation of the state of the art.

It will be remembered that the Munsey run, from Washington to Boston, angled along, taking the run of the roads, for a distance of 690 miles, the whole distance having been made within six days, which, considering the state of the roads, was regarded by the committee as a notable performance for "gasolines," for which the run was organized.

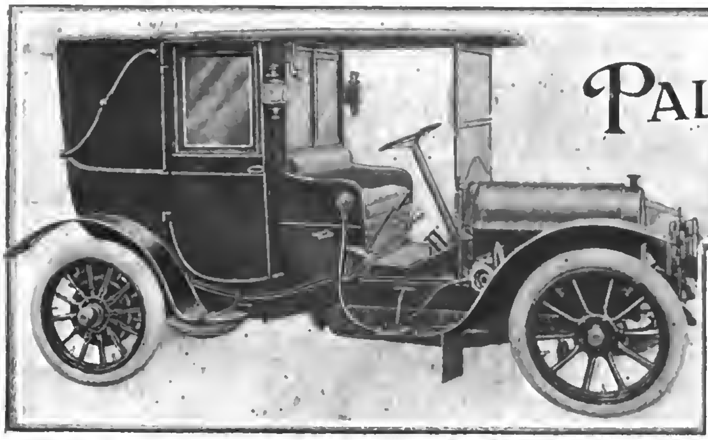
The Detroit Electric, as here illustrated, made this run; made it in good time, made it in good fettle, and made history in the doing, according to the best judgment of those who have some competence to judge.

It was a performance without an incident, from the car point of view, unless note is taken of two tire punctures and many surprised citizens who never did think that an electric would be able to stay in the run. To begin with, rain and general inclemency of weather rendered the going so difficult that the gasolines waddled about duck-fashion to a degree, and it is just this point that should be enlarged upon in discussing the sturdy Detroit electric.

The car illustrated is a regular stock Detroit, known as a victoria. The battery was just as this class of equipment is supplied to all Detroits, and in the run the performance was in the absence of any changes, either of battery or otherwise.



Detroit Electric Which Made Great Run in Munsey Tour.



Palmer Singer 1910 Models

Dropped Frame of Town Car Is Distinctive

CONCENTRATION, the aim of all American people, is the right word to apply to the method in which the Palmer-Singer Manufacturing Company, of 1620 Broadway, New York City, and Long Island City, is attacking the problem of automobile production for the coming season. By this means, and aided very materially by a model factory of large size, recently completed, the 1910 output will reach the figure of 4,000 cars.

Leaders in the line of cars will be the six-cylinder 60-horsepower car known as Model LXII, and the four-cylinder 30-horsepower machine called Model XXX, the latter being also produced, in slightly changed form, as a town car. All models are shaft-driven, have four speeds, with direct drive on third, multiple disc clutches. I-beam front axles, and many other noteworthy features. Space prevents a full description of the many good features of these three models, or even of the well-equipped factory, but the salient points of the six-sixty and the four-thirty will be mentioned in some detail.

Description of Big Six Engine—The motor is 4⅞-in. bore by 5½-in. stroke and develops its rated 60-horsepower at or below 1,200 revolutions per minute, reaching its maximum power at about 1,600 revolutions. The cylinders, pistons and rings are made of titanium iron, a very strong, dense and homogeneous metal, capable of taking a very smooth finish. These parts are given the final finish by grinding, which insures perfect accuracy. The long light pistons have four rings each, besides suitable grooves for distribution of oil upon the cylinder surface, and their tops are finished smooth to prevent the accumulation of carbon, and consequent misfiring and laboring.

Piston pins are hollow, with hardened and ground surfaces, and are secured in place by a set screw at each end, positively locked to prevent unscrewing. The nickel-steel drop-forged connecting rods are light and strong, due to careful distribution of metal, and of a length insuring but slight side pressure on the cylinder. Crank pin ends are lined with special metal bushings and the piston ends have bronze bushings.

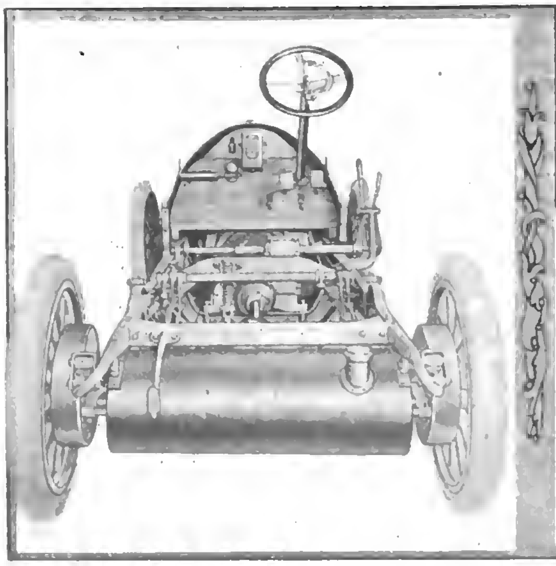
Inlet and exhaust valves, located on opposite sides of the motor, are 2⅜ in. in diameter in the clear opening and are made of a special heat-resisting grade of steel. Note that these valves are nearly half the diameter of the cylinder. The valve stems work through interchangeable bushings, easily renewed in case wear produces enough play around the inlet valve stems to allow air to leak in and affect the running at low speed.

Cams are accurately ground to a master cam and the camshaft gears are made with bronze rims and malleable iron spiders, a construction which greatly reduces the ringing noise to which these gears are liable. Noise is further reduced by enclosing the gears, which also protects them from dust and permits perfect lubrication. The exhaust camshaft carries small relief cams.

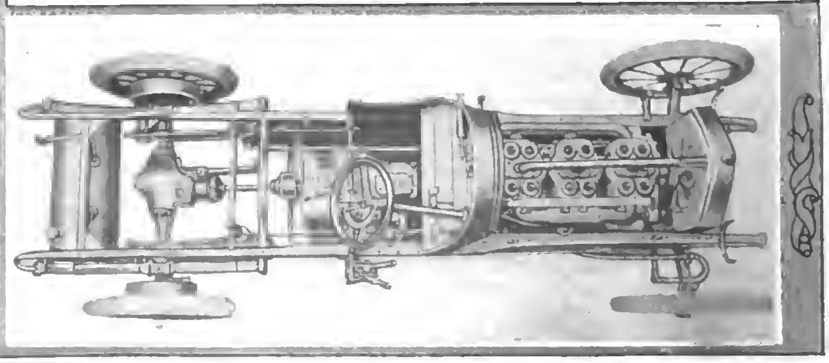
Suitable means are provided for bringing these cams into operation by shifting the entire shaft endwise. The relief cams then hold the exhaust valves open for part of the compression stroke, making the work of cranking the motor much lighter. Valve push rods work in hard bronze guides and have ample bearing surface for taking the side thrust of the cams.

Hardened and ground rollers at the lower end and adjusting screws with inlaid fiber striking blocks at the top, aid in maintaining proper adjustment of the valve mechanism and consequently produce quiet running and efficiency. The crankcase is made of aluminum, well ribbed and strong, and carries all crankshaft bearings in the upper half, the lower half acting only as a cover and oil reservoir.

Efficient Lubrication Very Important—The oil reservoir is cast integral below with the lower case and holds enough oil for 300 miles running. A gear pump draws oil from the reservoir and delivers it to a pipe extending the entire length of the upper case, from which copper tubes lead to the main bearings and to the camshaft gears. The crank pins receive their lubricant, through holes drilled in the crankshaft, from the excess oil supplied by the main bearings. The cylinders and camshaft bearings are lubricated by the oil splashed from the bottom of the case by the connecting rods. Every moving part is thus bathed in oil while the excess drains back into the reservoir, where it settles and is filtered before reaching the pump again. A float in the oil reservoir, with a tell-tale extension visible in a glass tube



From the Rear, Showing Dashboard Simplicity



Six-Sixty Chassis from Above Reveals Details of Construction in the upper half of the case, shows at a glance the amount of oil in the motor. This is useful in filling up and at other times.

Hammered steel from a drop forging made in one billet is the material of the crankshaft. Crank throws are sawed out, after which the shaft is heat-treated and machined. The final finish of the bearings is by grinding, giving a smooth and perfectly round journal. Provision is made at each end, where the shaft leaves the crankcase, to prevent the escape of oil.

Ignition Details—Only One System—Ignition is by Bosch magneto and batteries on all models, the latter being for starting only. The magneto is carried on a bracket at the right of the six-sixty motor and is driven by a pinion meshing with the camshaft gear. An Oldham coupling takes care of small errors of alignment and permits quick removal of the magneto. On all models, except the four-thirty and town car, a single coil, a dry battery of six cells and a high-tension distributor are provided for starting. The magneto and battery system each has its own set of plugs. The high-tension wires of both systems are enclosed in a metallic conduit on top of the cylinders, and the points of entry and exit are protected by insulation to prevent chafing.

Proper carburetion for a six-cylinder motor is one of the most difficult problems that an automobile engineer is called upon to solve. This company has devoted much time and expense to careful study of carburetion of six-cylinder motors, and believe that in the multiple jet type of carbureter the acme of simplicity, reliability and economy has been reached.

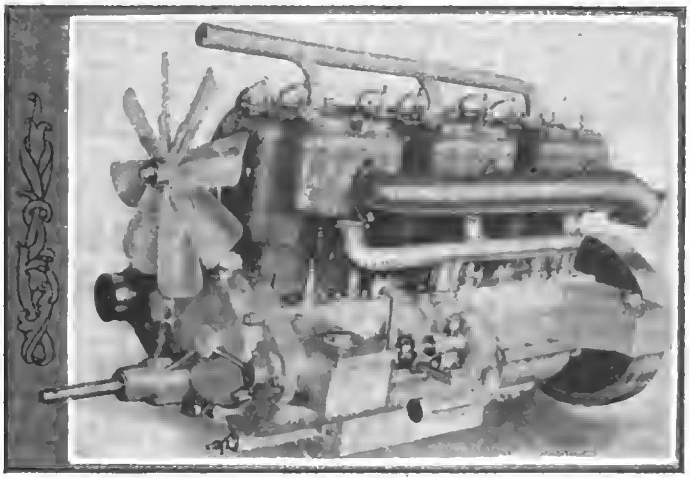
This company claims that it controls the patents on the multiple jet carbureter in this country and takes this opportunity of warning others from trespassing upon those rights. The carbureter contains the usual float and float chamber, from which fuel is led to three nozzles, each in its own Venturi air tube.

One of these nozzles is provided with an adjusting needle, the movement of which is limited to less than a full turn, and the air passage around this nozzle is always open. The other two air passages are closed at the top by check valves, which are controlled by a cam acting in unison with the throttle valve, so that the check valves open successively as the throttle is opened.

Cam adjustments are made at the factory and proper nozzle sizes fixed, leaving only the slight needle valve adjustment by which a purchaser may compensate for variations in altitude, fuel, or atmospheric conditions. Proper arrangements have been made to secure warm air for vaporizing the gasoline and preventing condensation in cold weather.

Features of Smaller Motor—Like its big brother, the smaller engine has cylinders cast in pairs, but contrary to it, the valves are grouped on one side. In size, the smaller engine, has a 4½-in. bore and a 4½-in. stroke. As to power, it delivers its rated 30 horsepower at about 1,250 revolutions per minute and reaches its maximum at about 1,650 revolutions. Much that has been said of the design of the six-sixty motor also applies to the four-thirty, so that only the minor differences need be mentioned.

The upper half of the aluminum crankcase carries the crankshaft bearings, which are special die-cast babbitt, as are also the crank pin bushings of the connecting rods. The hollow, hardened and ground piston pins are clamped tightly in the upper ends of the connecting rods and oscillate in bearings in the pistons.



Inlet Side of Palmer-Singer Six-Sixty Engine

Valves and camshaft are placed on the right side of the motor, while on the left side are the water pump and Bosch high-tension magneto arranged in line and driven by a single gear, but with Oldham couplings between, so that either can be removed without disturbing the other. This motor cranks easily enough to permit starting from the magneto without difficulty.

How the Transmission and Clutch Are Made—All the gears have very wide faces and are made of special steel, case hardened to resist wear, and are mounted on very large shafts, reducing deflection and noise to a minimum. Imported annular ball bearings of the highest quality are used throughout. The transmission is of the selective type—that is, any gear may be meshed with its mate without passing through any other gear.

The multiple disc clutch runs in an oil bath in the front end of the gear box. The discs are made of the finest quality of sawblade steel, having great wearing qualities, and will not burn out. This clutch permits of gradual and smooth starting of the car without shock to the gears, transmission, or occupants.

All rear axles are of the full floating type, in which the wheels are mounted entirely upon the stationary axle tube. The driving axles, which engage the wheels by jaw clutches, are subjected to torsional strains only. The wheels have imported annular ball bearings, while four-point adjustable ball bearings are used to carry the bevel gears and take their thrust.

Wheels and Running Gear Well Cared For—Tread is standard on all models, but the wheelbases vary. On the six-sixty, 127 in. is the distance, which in the four-thirty is reduced to 115. Town cars should be roomy, if anything, so the town car has 120-in. wheelbase. All front wheels have 10 spokes, and all rears 12. Wheels are of second growth hickory.

A KENTUCKY EDITORIAL

In discussing the growth of the automobile industry and commending THE AUTOMOBILE's stand for a code of laws that will protect all users of the highway, an editorial in the Louisville *Evening Post* has this to say:

One of the interesting features of modern life has been the growth of the automobile. It opens a new era in transportation, but what has been done is little compared with what is coming. Let us conceive the condition of our streets and highways when there are three or four automobiles where now we have one. It is not a long look ahead, but we must "look ahead" in order to develop the conditions of traffic under these circumstances which will protect the roads, protect pedestrians, protect the public who ride in the automobiles, and protect those that can have little or nothing to do with them.

We are glad to see that the Automobile Club of Louisville is considering these conditions in a broad and liberal manner. At a recent meeting the club voted to send letters to every owner of an automobile in the State recommending the passage of a bill, to be introduced by Senator Newcomb, making it a felony for anyone to use an automobile for any purpose without the consent of the owner. This will do something to protect the owners of the machines, and protect the people usually injured by this reckless and irresponsible use of the roads.

In New York so numerous have been the fatalities and so brutal have been the actions of certain of the chauffeurs that the feeling against the automobile is probably stronger now than it was three years ago. One of the principal newspapers devoted to this interest, The Automobile, demands a code of laws that will protect all users of the highway and will bring to rigid account men responsible for the disregard of the regulations, whether the responsible man be the owner or the chauffeur.

We are to consider that we are using locomotives on macadam roads which are not patroled as steel roads are, which are not protected by danger signals, which have no train dispatchers, across which men, women and children constantly go and along which all kinds of vehicles take their way.

It is manifest that we must have a code of laws which will clearly define the conditions under which these roads can be used, the maximum speed at which the automobile may travel at differnt points along the road, the rights of others to a joint use of these highways, and the restrictions upon all parties as to this use.

One of the first conditions of progress in this direction is obedience to the laws we already have. The cry for more stringent, and, in many cases, unreasonable regulations, is due to failure of many of the chauffeurs to pay the slightest regard to city ordinances, road rules, or the statutes of the State whenever they think they are unobserved.

It is to the interest of all concerned that the users of automobiles be not considered as being in a class by themselves. They are a part of the traveling public. They create a growing part of the traffic which must seek these streets and highways. They cannot (and reasonable men among them do not) claim any special privileges. The roads were here before the automobiles came, and were built by the common contributions of the whole community. The automobiles are entitled to use these highways just as other vehicles are, but they must be subjected to restrictions designed to secure to all the people the greatest benefits from the highway consistent with their common use.

Once upon a time there were daily press comments both rabid and prejudiced; now there is an evident desire to approach the subject in a liberal and unbiased manner. The situation, in plain words, is that the automobilists must assist in purging their ranks of the criminal offenders who arouse these threatened epidemics of antagonistic legislation which cause law-abiding auto owners unlimited trouble in preventing the swinging of the pendulum to the other extreme.

ART IN AUTOMOBILE BODIES

Although hardly so elusive as the Paris fashions in hats, automobile bodies still show enough of the same infinite variety to keep the average man guessing, and. incidentally, to provide a liberal profit for their designers and constructors. But recently we fancied that we had reached the day when at last a body was nothing more than a body should be; that is to say, a comfortable accommodation for a certain number of passengers, simply and economically built, and possessed of that grace and good taste inseparable from a structure well adapted to its work. We seem to have been mistaken.

To the British Isles we now owe, besides the monocle and the green hat, that specimen of the body-builder's art variously known as the "torpedo" and the "gunboat," though by the irreverent often dubbed the "bathtub." Its originator must have been one of those comic-supplement artists who delight to show an automobile in the act of tossing a benevolent old gentleman into the branches of an apple tree. Whether or no this surmise be correct, one easily traces the baleful influence of comic-supplement tradition in its lines.

The object of this design appears to be the complete obliteration of every natural body feature, reducing the automobile to the semblance of a submarine, from which the heads of the occupants protrude unnaturally. Its boasted advantages include none which have not already been obtained on bodies of normal design. Doors to the front seats were seen long ago. Dust raising concerns principally the underbody. Wind resistance is a negligible factor at any ordinary speed. Let us hope that the reign of the "torpedo" will be brief; its demise will certainly be unregretted. Present designs may not be perfect, but improvement does not lie in the direction of the "torpedo."

CHALMERS-DETROIT AND HUDSON COMPANIES TO SEPARATE

DETROIT, Dec. 20—In this city, automobile history is made while you wait, so that the announcement of the ultimate separation of the Chalmers-Detroit and Hudson companies into two distinct concerns, following closely upon the Studebaker E-M-F announcement, made a great stir. Ever since Hugh Chalmers purchased an interest in the Chalmers-Detroit Motor Company it has been his ambition to become the controlling factor. The formation in Detroit some time ago of the Hudson Motor Company paved the way for changes that will make this condition of affairs possible. Identified with the latter concern were a considerable number of Chalmers-Detroit stockholders, including Mr. Chalmers, R. D. Chapin, Howard E. Coffin and F. O. Bezner.

After July 1 next the two companies will operate as separate concerns, being owned by entirely different persons. Messrs. Chapin, Coffin and Bezner have traded their Detroit-Chalmers holdings to Mr. Chalmers for his holdings in the Hudson Company and a comfortable cash bonus, and will busy themselves with the affairs of the latter corporation after the above date.

Under the reorganization, officials of the Chalmers-Detroit Company will be: President, Hugh Chalmers; vice-president, Lee Counselman; second vice-president and factory manager, J. J. Brady; secretary, H. W. Ford; treasurer, C. A. Pfeiffer; chief engineer, George W. Dunham, now chief engineer of the Hudson Company.

E. R. Thomas, of Buffalo, it is understood, retains his holding and will continue to serve as a director in the Chalmers-Detroit Company.

Under this change Messrs. Chapin, Coffin, and Bezner gain control of the Hudson Company, which will be officered as follows: Chairman of the board, J. L. Hudson; president, R. D. Chapin; vice-president, H. E. Coffin; secretary, F. O. Bezner; treasurer and general manager, R. B. Jackson; sales manager, E. C. Morse.

When interviewed by a representative of THE AUTOMOBILE, Mr. Chapin had this to say concerning the proposed changes: "We were facing a business problem, and we met it in a business-like way. We have felt for some time that the field of both the Chalmers-Detroit and Hudson Companies was so broad that both should be worked to the limit. We decided that a rearrangement of our executive forces was the best thing to bring about the results desired.

"In connection with my associates, I have the greatest faith in the future of the light car business. I believe that companies such as the Hudson and Chalmers-Detroit, making good cars at low and medium prices, and in position to produce in large quantities, will reap the largest measure of prosperity within the next few years. It is our belief in this bright future for the maker of the light car that has influenced all of us to rearrange our line-up so as to take the utmost advantage of the opportunities offered.

"There will be no change in the policy of the Hudson Company, in its production of cars at a very moderate rate of price, with the highest possible quality that we can put into them. The unusual success of the Hudson "Twenty" roadster argues well for the plans we have in view respecting the future of the company.

"All of us have the most sincere respect for Mr. Chalmers and his ability, and our agreement is entirely a friendly one. The two companies will aim to work in close harmony and to help one another in every possible way in the future."

Mr. Chalmers expressed himself in a similar strain, when seen by a reporter for THE AUTOMOBILE. He said in part, speaking on the subject of the change and its influence on the two companies:

"We reached the conclusion that both companies would develop faster, and all concerned in them prosper more rapidly if there was more concentration of effort along definite lines on the part of some of the officers.

"It is sometimes difficult in the actual management of two distinct corporations for the same set of men to give each concern the full amount of attention that each one should have, and we felt that the Chalmers-Detroit and Hudson Companies each was large enough now to demand the individual attention of its own set of officers. These contemplated changes will not take place abruptly. We shall work into them gradually and naturally, so that the regular operations of either company will not be interrupted.

"I want to say that my association with Messrs. Chapin, Coffin and Bezner has been long enough for me to have learned to know them very well, and to appreciate their knowledge of the automobile field and their ability to carry on successful operations in that field; but, above all, I have learned to have the highest possible estimate of their integrity and ability. We have always been the best of friends and our business relations have been most pleasant. This deal is entirely friendly and will not in any way interfere with our business or personal relations in the future. It is the spirit of our agreement that the two companies, although they will be entirely distinct and operating along slightly different lines, shall continue to work close together and in perfect harmony.

"The policy of the Chalmers-Detroit Motor Company will not be changed in any way. We shall continue to make the Chalmers-Detroit "Thirty" and "Forty." It has been the established policy of the company to offer the public the greatest possible values at the prices asked, and we shall continue to follow this policy."

STUDEBAKER AND E-M-F DIFFICULTIES STILL UNSETTLED

DETROIT, Dec. 20—The legal controversy being waged between the E-M-F and Studebaker companies, and which still continues to be the leading topic in local automobile circles because of the far-reaching effects of the case whichever way it may be decided, took an unexpected turn last week when Judge Henry F. Severens, of the United States Circuit Court at Cincinnati, granted a temporary restraining order against the E-M-F Company preventing it selling cars to any company other than the Studebaker Automobile Company, of South Bend, Ind.

Judge Swan, of the United States District Court in Detroit, some days previously refused to issue a peremptory restraining order requested by Studebaker officials, and the matter was to have come up in his court Monday of this week, he announcing his determination to decide the question on the merits of the case.

Then Attorneys John S. Miller, of Chicago, and Henry M. Duffield, of Detroit, on behalf of Messrs. Fish, Studebaker and Eames, of South Bend, busied themselves and secured the temporary restraining order from Judge Severens, which is returnable in Kalamazoo, Wednesday, of this week.

The first intimation E-M-F officials had of this move was when copies of the order were served on the majority stockholders, the three complainants constituting the minority holders. Meanwhile, the E-M-F Company had proceeded along the lines originally laid down by Judge Swan, and filed its answer to the application of the Studebaker Company for a restraining order. The annulment of the contract with the Studebaker Company is admitted, but it is declared this action was taken only after the Studebaker Company had violated its contract in refusing to take the number of cars agreed upon, and that such action was sanctioned by a majority of the board of directors.

It is alleged that the Studebaker Company is not a manufacturing company, has a capital of only $100,000, and that it followed the method of making contracts with dealers to sell the car on a percentage basis; that it took advantage of the popularity of the E-M-F car to force dealers to take the sale of other cars in which the Studebaker Company is interested at low, unfair and discriminating discounts, not sufficient to compensate such dealers, with the result that the demand for the car fell off.

Inasmuch as the demand for E-M-F cars was created before the selling agreement was entered into, it is claimed, the only losses the Studebaker Company would suffer would be in the profits on sales, which are insignificant compared with the damage sustained by the E-M-F Company by reason of the Studebaker Company failing to live up to the terms of the contract. It is maintained in the answer that through failure of the Studebaker Company to take the allotted number of cars in October, November and December the E-M-F Company was put to a large expense in storing cars, and that if it is enjoined from selling its product the factory will have to be shut down. Accompanying the answer is a statement showing that with improvements the E-M-F Company has an investment of $2,582,681 in its six plants, and that it has contracts for material with sixty firms, aggregating $5,000,000. The answer discloses the fact that contracts made by the company for parts and materials are based upon the cost plus a fixed percentage of profits, so that all these firms would be somewhat affected should the factory be closed.

Counsel for the E-M-F Company argued against any continuance of the case, which had been set by Judge Swan for a hearing Monday. However, Judge Swan granted the request of the minority stockholders, who were desirous of having the temporary restraining order disposed of first, and the local case went over for a week, after a stipulation to cease advertising.

In the interim between its réscinding of the selling agreement with the Studebaker Company and the issuance of a temporary restraining order the E-M-F Company had been doing a land office business with agents from all over the country, who flocked here the moment it became known that the E-M-F Company proposed operating independently. Hundreds visited Detroit seeking the agency for E-M-F cars, and President Walter Flanders has for a week or more been the busiest man in the industry. Should Judge Severens decide, on the showing made, to grant a permanent injunction the entire aspect of the case might be changed. In that event it is difficult to see how a long-drawn-out legal battle could be avoided. Indeed, those familiar with the matter now insist that is what it will amount to in any event, as both sides are determined—the E-M-F Company to maintain its identity, it asserts, and the Studebaker Company to continue the selling arrangement it declares is still valid.

A NEWS BUDGET FROM AUTOMOBILEDOM'S HUB

DETROIT, Dec. 20—Manager John Gillespie, of the Detroit Auto Dealers' Association show, to be held in the Wayne Hotel Gardens, January 24-29, isn't a fatalist. Hence the fact that local entries to date exceed those of the Madison Square Garden show by the cabalistic thirteen doesn't worry him. So far 67 different makes of cars have taken space, or to be more exact have been crowded in. The Madison Square show advertises 54 exhibits of completed cars. And that is one of the reasons Manager Gillespie and officials of the association wear a smile that even their troubles in accommodating all who desire to show can not efface. Approximately 30,000 square feet of space is available at the Wayne Hotel Gardens. If there was twice as much it could all be filled with cars alone. As it is every foot is taken, and accessories manufacturers are barred. This has caused considerable dissatisfaction, but there was no alternative. Some day some enterprising mortals may provide Detroit with a hall suitable to the requirements. Until it does the hub of the automobile industry will have to worry along with the best it has, and content itself to have the annual event known as "the biggest little show," although, as entries this year indicate, aside from the limited accommodations, it has long since outgrown that classification.

No New Concerns—The past week was a notable one in several respects so far as the local field was concerned, not the least interesting feature being the fact that a careful survey of the situation shows that not a single new automobile company came into existence in Detroit. Where they have been coming so close together that an adding machine was required to keep tab on the total this is a truly startling condition, due, no doubt, to the fact that several who will get into the game shortly were occupied with their Christmas shopping.

That Parts Shortage—How seriously the threatened parts shortage will affect automobile makers in Detroit depends largely upon whom you talk with. All the manufacturers are keeping a stiff upper lip, and appear to be unconcerned. It is well known, however, that in many instances difficulty is already being experienced in getting parts, with the prospects even less encouraging the first of the year. This condition applies particularly to those producers of motor cars who are known in the trade as "assemblers," and who are almost entirely dependent upon other concerns for their supplies. The older established concerns, who were under way before the shortage loomed above the horizon, appear in a position to take care of themselves, and little anxiety is being manifested.

"One consolation lies in the fact that if the shortage really becomes serious it will result in a lot of experimental cars being kept off the market," said one veteran dealer, discussing the situation. "The old concerns will be able to pull through all right, but some of the newer ones that have just opened up and are planning big things will get some experience that will come high before it is all over, or I miss my guess." Another exemplification of the ill wind adage?

WHY WORCESTER RUN WAS ABANDONED

WORCESTER, MASS., Dec. 18—The endurance of the Worcester Automobile Club, scheduled for yesterday, was called off because of an insufficient number of entries. The reason given is that dealers were not able to get cars at this time, and another reason assigned is that the Boston dealers did not care to go up against the rules of the contest, which required a severe technical examination at the testing plant of the Worcester Polytechnic Institute. Last year there were upward of a dozen entries in the 200-mile run, and while nearly all of them finished with perfect scores so far as the actual driving was concerned but one car was given a perfect score.

PERHAPS A SPEEDWAY FOR COBE RACE

CHICAGO, Dec. 21—In considering a course for the 1910 Cobe Cup and Indiana Trophy races, the directors of the Chicago Automobile Club are inclined to give the preference to a speedway backed by local automobilists.

Plans for the speedway in question have been considerably elaborated. The site proposed is within easy distance of Chicago, both by steam and electric roads. The capitalists behind the speedway are willing to build the track and stands without attaching any liability to the club. They will take the chance of getting returns on the investment, either by conducting the races themselves or leasing the track to the club for that purpose.

DAYTON AD MANAGER ON SITUATION

Dayton, O., Dec. 20—At a time when it is freely admitted that the automobile business is passing through a second formative period, any comment or advice coming from those in a position to offer something worth hearing, and exegetical of the situation, is worth repeating. Gridley Adams, advertising director of the Dayton Motor Car Company, Dayton, O., makers of the widely known Stoddard-Dayton cars, has delivered himself of an analysis of the situation which will carry weight.

Commenting on the reported productions of the larger firms, Mr. Adams goes somewhat astray, for he says: "The real condition of the automobile industry to-day is far from what is generally understood by the outside public. They read that one manufacturer is going to build 10,000 cars, another 25,000, and still another 40,000 cars for the season of 1910.

Gridley Adams

"No one factory is equipped to turn out more than 4,000 to 5,000 cars a year. If more cars go out bearing the name of any one manufacturer, they are the product of perhaps a dozen factories, though 'assembled,' may be, in one. Their various parts are not made by themselves, but necessarily bought from part-makers or accessory-makers all over the country. Therefore, under the present condition of a great over-demand, how much regard can be given as to how one part-maker's part will bear relation to the quality of another part-maker's part? That isn't harmonious construction, but positive disorder. The old adage of a chain being no stronger than its weakest link was never more applicable than to many automobiles manufactured under some of the present rush-day methods. How many automobiles made on this 'thrown-together' plan will last even one season through? Where is there any chance of interchangeability of parts—which factory built the particular part that went into your particular car, and which you now want replaced—will it fit when it comes?"

On the "made entirely in our own factory" idea his remarks are more happy. Getting onto this subject, his remarks are pointed rather closely to the car in which he is interested, but nevertheless are based on a sound foundation. He says:

"We are not thinking of quantity. We try to see how good a car we can make. We make our parts interchangeable. We take good care of Stoddard-Dayton owners, and do it willingly and promptly. Everything of importance in the make-up of our cars (excepting the tires, magnetos, lamps, and wheels) are made in our own factory. All gray-iron castings, including cylinders, and all aluminum and brass castings are made in our own factory. All pressed-steel frames, drop castings, springs, bonnets, fenders, tanks, mufflers, and all pressed-steel parts we make ourselves; also our radiators, bodies, engines, front and rear axles, transmissions—in fact, we make 93 per cent of all the essential parts—more than is made by any other manufacturer in the world. Under these circumstances we must be modest when it comes to quantity. We expect to make only about 2,500 cars this season. But they will all be made in our own plant, made carefully, every part fully inspected, every car thoroughly tested before it goes out into the automobile world bearing the name and guarantee of 'Stoddard-Dayton.' It is for this reason that we are sure—we know—the exact quality of everything—and its quality relation to every other part—that enters in the construction of Stoddard-Dayton cars. And our guarantee to every buyer of a Stoddard-Dayton car is based upon this absolute knowledge.

"We are way behind in our 1910 deliveries and we are rather proud of the fact. It's the best indorsement of quality and guarantee that an automobile buyer could ask for."

NEW BOOKS FOR AUTOMOBILISTS

Vehicles of the Air—Victor Lougheed, the author of "Some Trends of Modern Automobile Design," has, like many other automobile engineers, taken up the problem of mechanical flight. His work on this subject is represented by a massive volume of 479 pages, published by the Reilly and Britton Company, Chicago. The intention apparently has been to include between the covers complete and exhaustive treatments of every branch of art and science into which the experimenter might be led. To this end much matter has been retained which, at first glance, seems irrelevant. However, the great body of the contents is so much to the point that this fault is easy to forgive.

Of the greatest interest to all who approach the subject from the scientific point of view are the experiments and calculations of Professor J. J. Montgomery, of Santa Clara, Cal., on the laws of the effect of air currents on curved surfaces. These calculations seem for the first time to cover completely the mathematics of the question, and should prove invaluable in calculating the proper curvatures for aeroplane surfaces. Incidentally, Professor Montgomery proves that the curve should be parabolical in cross section longitudinally. This confirms the present practice of all the most prominent designs.

The practical man who is considering building a machine of his own will find abundant data. Working drawings, with dimensions, are given of the Santos-Dumont, Blériot Type XI and Antoinette monoplanes, and the Wright, Curtiss, Voisin and Cody biplanes, as well as of the Montgomery tandem monoplane glider. The information is so complete that a good mechanic could produce any of the machines almost exactly.

The patent question is treated very fully. The text of the Wright, Montgomery, Chanute, Mouillard and Lilienthal claims is given complete, with reproductions of the original drawings.

Mr. Lougheed is an enthusiast on the possibilities of aerial navigation. His idea of the future seems well expressed by the lines of Tennyson, which he quotes in his introduction:

> ". . . the heavens fill with commerce, argosies of magic sails,
> Pilots of the purple twilight, dropping down with costly bales."

He is an ardent believer in the aeroplane as against the dirigible balloon, although the book maintains a fair and impartial attitude. In Mr. Lougheed's words, "it (the dirigible) is accorded such attention as seems demanded by its present prominence rather than by its future prospects."

On the whole, the book is one that cannot be too highly recommended, both to students and to mechanics and inventors. It is illustrated by 130 drawings and 140 half-tones. In conclusion is given a very complete glossary of aeronautical terms and a list of all recorded heavier-than-air flights up to November 3, 1909, which are said to total 35,000 miles.

WILL WORK FOR LIGHTS ON ALL VEHICLES

Worcester, Mass., Dec. 18—The directors of the Massachusetts State Automobile Association had its meeting at the rooms of the Worcester Automobile Club yesterday afternoon, there being present Lewis R. Speare, Boston, president of the American Automobile Association; Atherton D. Converse, Winchendon, president of the association; A. E. Lerche, Springfield; W. H. Chase, Fitchburg club; James Fortescue, Bay State Automobile Association, Boston, and John P. Coghlin and Daniel F. Gay, Worcester Automobile Club. The principal business under discussion was plans for the legislative committee, and it was voted to work for a light bill on all vehicles, and also for legislation to iron out the many little kinks which exist in and around Boston.) The rules of the City of Boston relative to automobiles are unfamiliar to many automobilists in other sections of the State and frequent arrests are made on technicalities. It is the desire of the State Association to remedy these conditions. At least, that is the announced desire, and there seems to be no reason to doube their word.

American Five-Ton Truck Carrying Huge Load of Lumber

TRUCK SUCCESSFULLY CARRIES LUMBER

BUFFALO, N. Y., Dec. 20—One of the sights of this town is a huge motor truck more than covered—almost hidden—by a load of lumber. This vehicle, which one of the Buffalo lumber companies put into use not so very long ago, has made a reputation for itself. It is the product of the American Motor Truck Company, Lockport, N. Y., and is rated at five tons carrying capacity.

As shown in the picture, however, the load consists of over 7,000 feet of lumber, with a total weight of seven tons. The truck has been in this service for over three years, and the last report of the operators regarding the expense of operation and maintenance for twenty-two months, covering all items but driver's wages, was but $985. Of this total $285 was expended on tire repairs, leaving only $700 for gasoline, oil, waste and general repairs over a period of nearly two years. The truck is still rather frisky.

CORBIN ENGINEER FAVORS SHORT STROKE

Among the many big problems with which the automobile engineer is early confronted, and to which he must give attention, no one has excited more discussion than the matter of length of stroke. Beginning about a year ago abroad, following the success of cars in the English Four-inch race, American constructors began to give the matter their best attention.

Even to-day the subject has not been settled to the satisfaction of all concerned. Many makers have adopted the long stroke, while many others hold to the short stroke. The advantages of the latter are briefly summed up by one advocate, Guy Hutchison, secretary and sales manager of the Corbin Motor Vehicle Corporation, New Britain, Conn., as follows:

"Gasoline motors are not like steam, relying on the slow expansion of gas, but are impulse motors, where the pressure is very high for a short time, and after that can be practically neglected; therefore the piston traveling an equal distance in the same time revolves the crank further on a short-stroke motor, thereby giving more power. The short-stroke motor has shorter connecting rods, lower cylinders, smaller crankcase and lighter flywheel, all of which saves weight. The lower cylinders give a lower center of gravity, another important feature.

"The vibration is less with a short-stroke motor because each impulse is applied with a smaller lever arm. For the same reason the strain on the transmission, universal joints and level gears is less like a hammer blow. Other advantages of the short-stroke motor are that it cranks easier, is more economical of gasoline because of its smaller piston displacement, accelerates quicker and is capable of higher speed."

Elmira, N. Y.—The Charles W. Bishop Company has opened a new garage on State street, near Church, with all the modern conveniences, including a repair department equipped with complete machinery and appliances.

VALUE OF 1,600-MILE NON-STOP RUN

Among the buying public there is a tendency to place too much dependence upon speed trials and too little on reliability of endurance runs, which properly show the ability of the cars under ordinary conditions such as the average buyer is likely to meet. Speaking on this general subject, but referring specifically to the recent trip of the Jackson "Mud Hen," F. L. Holmes, general manager of the Jacobson Automobile Company, Jackson, Mich., expressed himself as follows:

"Very few people realize what a 1,600-mile non-stop run like this one means. The car was in charge of E. P. Blake, of Boston, accompanied by Dr. Charles Percival, both of whom went over this severe trip for the second time. The course followed ran from Jackson, Mich., to Bangor, Me. Runs of this character do more to demonstrate the superiority of the car than any number of races or short speed contests. Reliability and durability, together with strength and power, are more to be sought for, and 1,600 miles in the midst of winter over rough and frozen roads is a long drive, and the motoring public are not apt to pass over lightly the second performances of Messrs. Blake and Percival without realizing the full significance of covering the distance named in the short time they did and the condition of the weather and the roads. At this time of year few motorists venture on long drives, and 1,600 miles now means a strain that 7,000 miles, or a fair season's mileage average, for the ordinary owner. In fact, few cars average that distance in a year. Figure out the ride from Jackson, Mich., to Bangor, Me., together with the fact that the engine and car ran day and night, rain or snow, and that during the run the engine must not be stopped for any reason, and the magnitude of the task performed by Messrs. Blake and Percival for two successive years is apparent.

"The statistics of this run are most interesting, and show the stupendous task of the car and the component parts. In the run the motor loyally turned over without a single stop or hesitancy 3,555,000 times, during which time the carbureter delivered into its hungry and never satisfied cylinders just 7,104,000 charges of gas. Just think of the possibility of failure on this run; a deviation of a fraction of a second, a dragging wire, a clogged carbureter, or a hundred and one things would have been sufficient to have put to a stop this continuous run. Take the magneto alone, which never faltered, and which for hundreds of hours generated 7,104,000 sparks to fire these 7,000,000 charges of gasoline to furnish the propulsive energy for the 1,600 miles. This same energy and horsepower developed on the 1,600 miles was sufficient to raise the car into the air a distance of 560½ miles. There is also another interesting point, and that is the nervous and physical condition of the men who have twice made the trip. It's marvelous!"

PHILADELPHIA TRADESMEN TO HAVE HOME

PHILADELPHIA, Dec. 20—At last week's annual meeting and election the showing made by the Philadelphia Automobile Trade Association was so encouraging and the future prospects so bright, that the much-discussed project of a clubhouse, when revived, found a large majority of the members in a receptive attitude, and, as a result, President Wister appointed W. J. Foss (Pierce-Arrow), Allen Sheldon (Premier) and A. E. Maltby (Winton) a committee to secure suitable quarters. This committee went to work at once and after a thorough search secured a lease on a portion of the building now in course of erection at the southeast corner of Broad and Callowhill streets, about midway of "Automobile Row." The plans contemplate a suite extending across the entire front of the building, with meeting, committee and dining rooms, secretary's quarters, kitchen, lavatories, etc. Here will be established a clearing house for the local automobile trade, and quarters for visiting tradesmen. Secretary J. H. Beck will be on duty constantly, and it is proposed to ultimately extend the accommodations to include a comprehensive automobile library and tourists' bureau, where travelers may obtain information of all kinds. The new quarters will be ready for occupancy about March 15.

INJUNCTION AGAINST PRICE-CUTTERS

New York, Dec. 20—In a trial case, which has just been held, it appears as if the pernicious price cutting resorted to by certain small dealers may be stopped once and for all. The Circuit Court of the United States for the Southern District of New York has just granted an injunction against cut rate dealers who handle the Klaxon Warning Signals, in the case of the Lovell-McConnell Manufacturing Company, et al, vs. the E. J. Willis Company.

From the papers on file in that case, it seems that the Klaxon signals, which are covered by numerous patents, are sold under a conditional license fixing the retail price of the large model, type L, at $35, and the smaller model, type S, at $30, with a maximum discount of 5 per cent. for actual cash and that certain cut rate houses have recently been selling for retail at a price considerably less than the license price.

The owners of the Klaxon patents decided to make an example of such offenders and upon their complaint the E. J. Willis Company was obliged to submit to a decree signed by U. S. Circuit Judge Lacombe, ordering the injunction asked for.

It seems that the Federal law with respect to fixing the license retail price of patented articles is well settled and that the Klaxon people will have no difficulty in stopping every price cutter. It may be of interest to our readers to know that the decision in the above case follows a well settled principle of patent law established by many Federal decisions. (See 166 Fed. Rep. 117; 159 Fed. Rep. 175; 123 Fed. Rep. 424, and cases there cited.)

FRANKLIN PLANT STILL EXPANDING

Syracuse, N. Y., Dec. 18—The H. H. Franklin Manufacturing Company has bought four parcels of land on the south side of West Marcellus street, between Harbor Brook and Magnolia street. The consideration is private. The company is now owner of the entire frontage on the south side of West Marcellus street, between South Geddes and Magnolia streets. Each parcel extends back to previous holdings of the company. It was stated by representatives of the company that the property was obtained for future use rather than for any immediate building proposition. The West Marcellus street frontage from Geddes street to Harbor Brook is already built upon. The new move rouses expectations of more factory extension for this rapidly growing business.

23,000 CARS REGISTERED IN OHIO

Columbus, O., Dec. 11—The State of Ohio has issued 23,000 automobiles. License-tag number 23,000 was given out to-day to Miss M. L. Ferrin, 3666 Reading Road, Cincinnati. Fred H. Caley, State registrar of automobiles, estimated that fully 40,000 cars will be registered by the department during 1910.

AMERICAN AUTO EXPORTS STILL GAINING

In the monthly summary of exports and imports published by the Department of Commerce and Labor the increase in American automobile exports to foreign countries, principally European, shows a very marked increase over even as good a year as 1908. This continued setting of the tide away from us is a most welcome sign to such American firms as are about to engage to a greater or less extent in the bid for European business.

For the month of October the exports were 338 complete cars and parts sufficient to bring the total value up to $522,769, as compared with 106 cars and a value of $213,775 for last October. As an indication of the class of cars exported, however, it should be noted that the average value per car has fallen from $1,560 of October, 1908, to $1,300 per car for this October.

For the whole year, including October, the statistics show that 2,764 cars were exported, the total valuation of cars and parts reaching $6,622,626. The former is an increase of 44 per cent over 1908, while the latter improves on last year's figures by 47 per cent.

The detailed figures by countries follow:

Country	Month Oct., '09	Per Cent Change	'09, Inclu'g October	P. C't Change
British North America	$157,314	221.0	$2,120.600	102.5
United Kingdom	121,208	91.5	1,839,772	14.6
France	29,839	435.0	789,735	46.6
Mexico	57,682	90.0	375,153	50.6
Other Europe	20,533	96.7	302,968	49.6
West Indies and Bermuda	12,643	*19.2	232,137	69.4
Italy	......	.....	214,430	*3.3
British Australasia	30,226	91.3	192,337	156.0
South America	11,235	219.0	158,701	56.0
Germany	3,154	*45.0	157,974	3.9
Other Asia and Oceania	58,433	473.0	138,216	20.0
Africa	13,336	918.0	59,123	700.0
Other Countries	3,985	1,270.0	25,828	24.6
British East Indies	2,587	1,420.0	15,652	*33.9

*Loss; all other gain.

During the same two periods of time the imports showed a marked increase over last year, but not in any such proportion as the exports above. The month, in fact, showed a loss of some $36,654, but the year revealed a gain of $612,508, with figures of cars $2,509,271, and parts $740,455.

All countries but Germany and the United Kingdom showed a loss for the month, the year's figures being about the same in this respect. In the table above attention is called to the value of our exportations to English-speaking countries, or those controlled by English-speaking peoples, these amounting to three-quarters of all cars and parts exported. In imports the same does not hold, France—losing steadily each year—furnishing this year slightly more than half.

Los Angeles, Cal.—The White Company is building a 185 by 55-foot garage on Flower street between Twelfth and Pico, which will accommodate 140 machines. The entire front is to be finished in white tile. A 50 by 69-foot salesroom is included.

Employees of the Mechanical Department of the New York Pierce-Arrow Branch

This picture, taken on the roof of the building occupied by the Harrolds Motor Car Company, 233 West Fifty-fourth street, the Metropolitan agents for Pierce cars, gives some idea of the magnitude of the business done there.

Combination Hose and Chemical of Fire Department, Westfield, Mass.

The above illustrated fire apparatus, which is fitted to a Pope-Hartford chassis, has been in active service since last July, and has proved its efficiency on more than one occasion. The local authorities state they would not go back to the horse-drawn equipment, even if the cost of the new outfit was double what was paid for it

Very Long Taxicab Trip—One of the longest taxicab trips on record was recently made in the South by W. P. McManus, of Chicago, in a Cartercar. Mr. McManus is a big, busy man, who appreciates the value of time. He was at Atlanta, Ga., and wanted to make the run to Savannah, stopping at several small towns on the way and looking after business matters. Being desirous of saving as much time as possible in the transaction of this business, Mr. McManus engaged a taxicab from the Savannah Taxicab Company, which was going to be driven after the Atlanta show to Savannah by W. C. Mahoney. It is understood that a special rate was made for the whole trip. Another feature connected with the incident which makes it rather interesting is the fact that upon the arrival of the car at Savannah Mr. Mahoney discovered that a baby daughter was awaiting him at his home.

New Brake Lining—Cactus cloth, the outgrowth of Burbank's efforts to put the cactus plant to some use, may turn out to be just the thing the automobile business needs. During the past year J. D. Maxwell, designer of the Maxwell line of automobiles, has tested various brake lining materials and he now states that cactus fiber is not only the equal of asbestos, but possesses a number of qualities which make it highly desirable for the new purpose. Though no definite information is given in regard to the process by which the new material is made, it is stated that the braking and wearing value of the various materials tested rank as follows: Cactus fiber, asbestos, cork, red fiber, camel's hair, hickory blocks boiled in oil, hickory blocks, dry; cast iron.

Capital Stock Increased—With business better than ever before, many concerns are extending their field of activity. To do this it is often necessary to have more capital, so we hear of many increases in capitalization. Among the New England makers who have been forced to this step is the Gilbert Mfg. Co., New Haven, Conn., which has recently taken over the F. E. Bowers Company, New Haven, the latter being the manufacturers of the well-known Bowers carbureter. The company has had a very successful year and under the new officers expects an even better one in 1910. The new officers are: F. E. Bowers, president; E. B. Spalding, treasurer; L. F. Meyer, secretary, and W. A. Rutz, sales manager.

Now an Aeroplane Magneto—With the rapidly increasing use of aeroplanes has come about an incessant demand for a magneto of especial lightness, but just as reliable and dependable as any other able to be used on these air machines. Lavalette & Co., makers of the Eisemann Magneto, have brought out a new magneto built especially for use in aeronautic work, which is lighter than those used in motor cars, though every bit as powerful. Part of the instrument is made of aluminum and the heaviest model weighs only 16½ pounds, while the lightest of the four-cylinder type weighs but 11 pounds. The company is now in a position to furnish from stock five different styles of this new magneto.

New Parts Company in Indianapolis—The field of parts manufacturers in the Indiana city will be augmented by the Stutz Auto Parts Company, located at Tenth and Canal streets. This corporation has been recently organized to make and sell the Stutz rear axle and transmission. The latter will be made in two sizes, one for 20-25 horsepower and the other 30-40 horsepower, both three speeds, and operated selectively. The officers of the new company are: H. C. Stutz, president; H. F. Campbell, secretary and treasurer, and C. E. Stutz, general manager.

More Baltimore Taxicabs—Plans are on foot to reorganize the Stewart Taxicab Company, of this city, with a nominal capital of $100,000 by well-known local capitalists. While the company intends to operate in Baltimore and add about twenty-five additional cars to the present service, it expects to eventually extend its operations to other large cities. The idea of the company is to take over the entire livery business of Stewart & Company, including taxicabs, horses, vehicles, etc., and retain Mr. Stewart as Baltimore manager.

Protest Against Raise in Rates—With a number of other automobile manufacturers the H. H. Franklin Mfg. Co., Syracuse, N. Y., has protested against the raise in rates recently made by the Trans-Continental Freight Association for shipments across the country. The manufacturers are seeking readjustment or postponement until shippers and carriers can get together. The interest in the change may be judged from the fact that the Franklin bill amounts to $75,000.

Pope Mutual's Smoker—The eighth annual smoker of the Pope Mutual Benefit Association was held in the dining hall of the Pope Mfg. Co.'s factory at Hartford, Conn., Thursday evening. Albert L. Pope, Charles E. Walker, Wilbur C. Walker and A. W. Pope were present as guests. The business report showed $1,500 in the treasury. During the past year $1,200 has been paid out in sick benefits and $150 in death benefits.

Fire in Racine, Wis.—The plant of the Racine Mfg. Co., a manufacturer of automobile tops, was destroyed by fire December 12. The loss was $600,000, of which $250,000 was covered by insurance. The fire started in the mill room of the plant, which comprised six buildings and occupied a city block.

Trucks from Bay City, Mich.—An automobile truck manufacturing company, under the name of the Toeppner Bros. Mfg. Co., has been organized by a dozen or more local capitalists, with a stock of $100,000, of which half is paid in. The new company absorbs the Toeppner Bros. Carriage Company, and will use the latter's plant temporarily.

Lectures to Be Continued—So interesting have the free monthly lectures of the New York School of Automobile Engineers become that the management has decided to continue them throughout the season. At each one of the sessions the building at 146 West Fifty-sixth street has been uncomfortably crowded.

IN AND ABOUT THE AGENCIES

New Selling Agency for Q M S Parts—It is announced by the Q M S Company (Quincy, Manchester, Sargent) that a new selling firm has been organized to be known as the Motor Parts Company, which will hereafter handle their automobile specialties. Of the new concern, W. D. Sargent is president, F. F. Kister secretary and treasurer and C. H. Holbrook, sales manager. The general offices of the Motor Parts Company are located at Plainfield, N. J., from which point the territory east of Detroit will be covered. In the West their automobile step business will be taken care of by John C. Hoof, with offices in the First National Bank Building, Chicago. On their Auto Cle Wrench business, as in the past, the Factory Sales Corporation, 1438 Michigan avenue, Chicago, will act as distributing agents for the Western territory, and the Frank Mossberg Company, Attleboro, Mass., for the Eastern territory.

Speedwell in South and West—The Speedwell Motor Car Company announces the following agencies for 1910: Capron-Wright Automobile Company, Omaha, Neb.; H. G. Carter, Los Angeles, Cal.; Hickman & Diggs Automobile Company, Sasramento, Cal.; Racine Auto & Boat Company, Seattle, Wash.; Speedwell Motor Car Agency, Birmingham, Ala.; J. B. Alsop, Richmond, Va.; W. W. Lynn, Lynchburg, Va.; Gentilly Automobile Company, New Orleans, La.; Houston Electric Appliance Company, Houston, Tex.; Edward Moyle, Savannah, Ga.; T. W. Simpson, Abilene, Tex., and the Escambia Motor Car Company, Pensacola, Fla.

Chalmers - Detroit, Philadelphia — A change has been made in the title of the firm which will represent the Chalmers-Detroit car in the Quaker City. A few weeks ago George W. Hipple, the manager, authorized the statement that the title would be the Chalmers Motor Company, but last week it was officially changed to the Chalmers-Hipple Motor Company, with Hugh Chalmers, of Detroit, and Mr. Hipple making up the new firm. The latter is also a member of the Levy-Hipple Motor Company, of Chicago.

Franklin, Cleveland—The Franklin Automobile Company, which conducts a number of selling branches for the H. H. Franklin Mfg. Co., announces the opening of a Cleveland branch. This will be the tenth branch of the company and will be ready about January 1. C. H. Rockwell, formerly assistant sales manager of the manufacturing company, will be manager of the branch, being now in Cleveland making arrangements.

Glide, West and South—For the season of 1910 the Bartholomew Company announces the following new agents for Glide cars in the West and South: Muskogee, Okla., L. R. Kershaw; Los Angeles, Cal., W. A. Shafer; Page, N. D., Page Machinery & Auto Co.; Minneapolis, Minn., Auto Storage & Repair Co.; Atlanta, Ga., W. J. Dabney Implement Co.; Jacksonville, Fla., Fred E. Gilbert Garage.

Everitt "30" and Matheson, Philadelphia—The Matheson car, which for the past year has been represented in Philadelphia by a branch, with W. Wayne Davis as sales manager, will be transferred to the Wayne Davis Motor Company, which recently acquired the Quaker City rights for the Everitt "30," with quarters in the original establishment at Broad and Green streets.

Martin and Hart-Kraft Commercials, Philadelphia—D. P. S. Nichols, Broad and Vine streets, has landed the Philadelphia agency for the Martin motor wagon; and the Thomas Wagon Company, 1338 Race street, will represent the Hart-Kraft delivery wagons, made in York, Pa.

Auto Supply Company, New York City—This old supply house has recently removed from 1733-1737 Broadway to Columbus Circle, Broadway and Fifty-ninth street, where a complete line of automobile supplies, wearing apparel, tools and hardware will be carried.

Fiat, Chicago—The Fiat Automobile Company has a new building under construction at 2347 Michigan avenue which when completed will be one of the finest on Automobile Row. The territory is under the charge of Harry T. Clinton.

Austin, Birmingham, Ala.—George B. Kelley, superintendent of agencies for the Austin Automobile Company, has secured the Pullman Automobile Company as representative in this city for the Austin line for the coming year.

PERSONAL TRADE MENTION

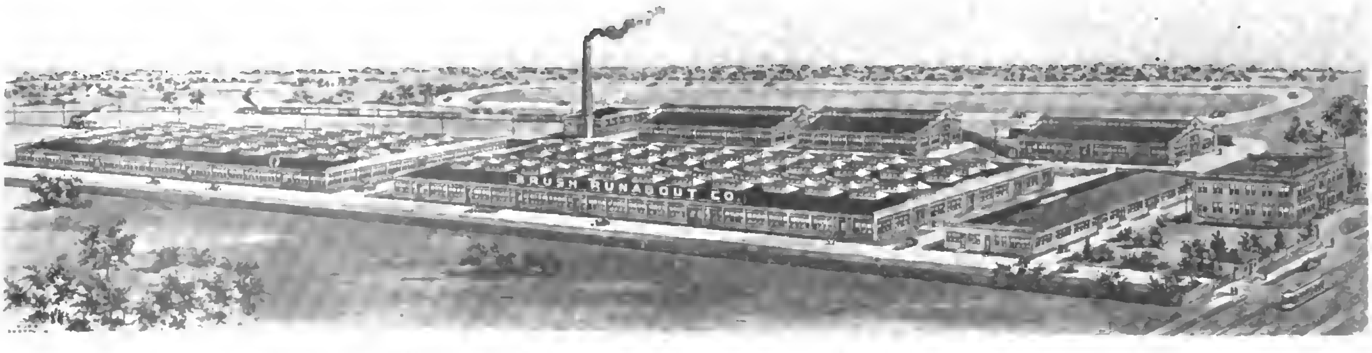
C. W. Moody, formerly manager of the Pennsylvania Rubber Company's Chicago branch, has accepted the position of general sales manager of the Swinehart Tire & Rubber Company, Akron, O. Mr. Moody is well and favorably known in the automobile trade, having been in the tire business for the past five years in Chicago. The Swinehart company has enlarged the factory and expects to deliver 100 tires per day during January and February, increasing the output still more after March 1.

Henry M. Duncan, a well-known pioneer of the automobile industry in New York, and formerly connected with the carriage trade, is now secretary and general manager of the Westchester Appliance Company, manufacturers and jobbers of automobile accessories and supplies, with headquarters at 1315 Canal Place, New York City. Mr. Duncan is prominent as one of the most versatile after-dinner speakers, and is frequently the *pièce de resistance* of automobile gatherings.

J. R. Windsor, formerly of the E. R. Thomas Company, has been appointed sales manager of the New York branch of the Allen-Kingston Motor Company, located at 1934 Broadway.

S. J. Rowe, who has been designer for the American-La France Fire Engine Company, will in the future devote his time to the Rowe Motor Company, of which he is president.

J. M. Hill, according to a statement from the Alden Sampson Manufacturing Company, Pittsfield, Mass., has resigned and is no longer connected in any way with the company.



New Home of Brush Runabout Company, Detroit, Mich., with 200,000 Feet Floor Space, Covering 38 Acres

Information for Auto Users

Michelin Anti-Skid Tires—The Michelin Company claims to have invented the anti-skid tire in its usual form, the familiar steel-studded leather tread. This tire was first brought out in 1905, and was used by the late Leon Thery on the Brasier cars with which he twice won the Gordon-Bennett.

The treads of these tires, as well as the wearing surfaces of the side walls, are protected by a tough but flexible band of ox-hide, which forms an integral part of the tire. In this band are riveted from three to five rows of hardened steel studs. By this construction the full resiliency of the tire is preserved, because the lower side walls, the parts immediately outside the beads, are of rubber, and permit the tire to absorb all shocks and jars, the same as any other good pneumatic tire. At the same time the ox-hide band protects the tread from cuts and punctures, and so prolongs the life of the shoe.

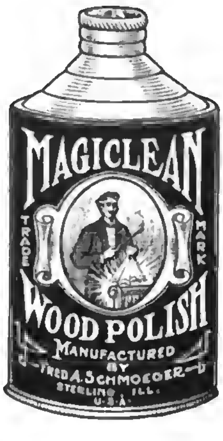
MICHELIN ANTI-SKID TIRE

These tires are especially recommended for winter driving in the city. The danger of skidding is very great when driving over Belgian block, brick or asphalt, especially after a light rain or snowfall. Anti-skid tires practically obviate any possibility of sidewise movement. They are made both in metric and in American sizes.

"Stay Shiny" and "Magiclean" Wood Polish—Both of the foregoing articles are made by the Sterling Stove Polish Company, of Sterling, Ill., and have

"STAY SHINY" COMES IN SMALL TIN CANS

made a reputation for themselves through their intrinsic merit. "Stay Shiny" is a transparent liquid that prevents tarnish and oxidization of all exposed polished metals, by forming a thin, invisible coating over the surface of the metal. It produces a beautiful lustrous finish, as hard as flint and smooth as glass, that is not affected by weather, heat, rain or mud, effectively preserving the original high polish indefinitely. It is easy to apply and easy to remove when desired; dries in a few minutes and does not get sticky or greasy; is elastic, won't crack, chip or peel off. A sample of its work supplied by the makers shows a section of old brass polished and treated with "Stay Shiny" that has been exposed to all kinds of weather for three months and still preserves the original very desirable luster.



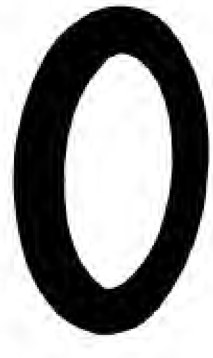
"MAGICLEAN" WOOD POLISH

"Magiclean" wood polish is making a big hit with automobilists and is made under the exact formula of the famous German "Holz Glanz." It is a scientific liquid oil preparation, being entirely liquid, requiring no shaking and contains no solid or coloring matter, acids, soap or alkali. It puts new life into the varnish and surfaces and instantly removes all dirt, grease, finger marks, cloudiness and mud stains and does not leave the surface sticky, greasy or dust catching, but with a hard, glassy, lasting luster.

"Swivelaction" Bumper—Some automobile drivers should be compelled by law to carry bumpers on their cars. Other drivers, usually the most careful, provide them from choice. Of their utility there can be no doubt, both as a protection to the automobile on which they are mounted and to others.

The "Swivelaction," the bumper brought out by the National Sales Corporation, 232 West Fifty-eighth street, New York City, has several novel features, from one of which it takes its name. The bar which extends across the front of the car is connected by two swivel joints to pivoted levers working in slotted sleeves against flexible spiral springs. A blow on the full face of the bar is absorbed by the springs directly; a glancing side blow, as when turning a corner or striking an obstruction with one end of the bar, is taken care of by the swivel joints, which carry the jar to the springs. The "Swivelaction" is so designed that the bar sets higher than usual, thus affording the maximum protection to the lamps and radiator, but at the same time it does not interfere with the cranking of the motor. The springs are carefully tempered and provide for a compression of 1,500 pounds.

Carpringco Tires—In placing Carpringco tires before the automobile public the manufacturer, the New Jersey Car Spring & Rubber company, Jersey City, N. J., lays special stress on the fact that the tires are very carefully made by hand of the highest possible grade of materials and are subjected to a supervision in manufacture that precludes all possibility of defective material reaching the purchasers. The company announces that it has adopted a new vulcanizing process by which all moisture is eliminated during this important stage of tire making, the result being that no part of the fabric is subjected to the danger of early rotting from that and all other causes.



CARPRINGCO HAND-MADE TIRE

In the case of the anti-skid tire the leather tread and the rubber carcass are treated in such a way that separation is almost impossible, thus minimizing the danger of the leather facing peeling off, and in other ways giving trouble before it could be reasonably expected to do so. The makers also guarantee that the same high quality of rubber enters into the manufacture of its red rubber inner tubes as in the type of gray color, and that this matter of quality can be better appreciated at this particular time than in the past, as the scarcity of high-grade rubber encourages the use of compounded stock.

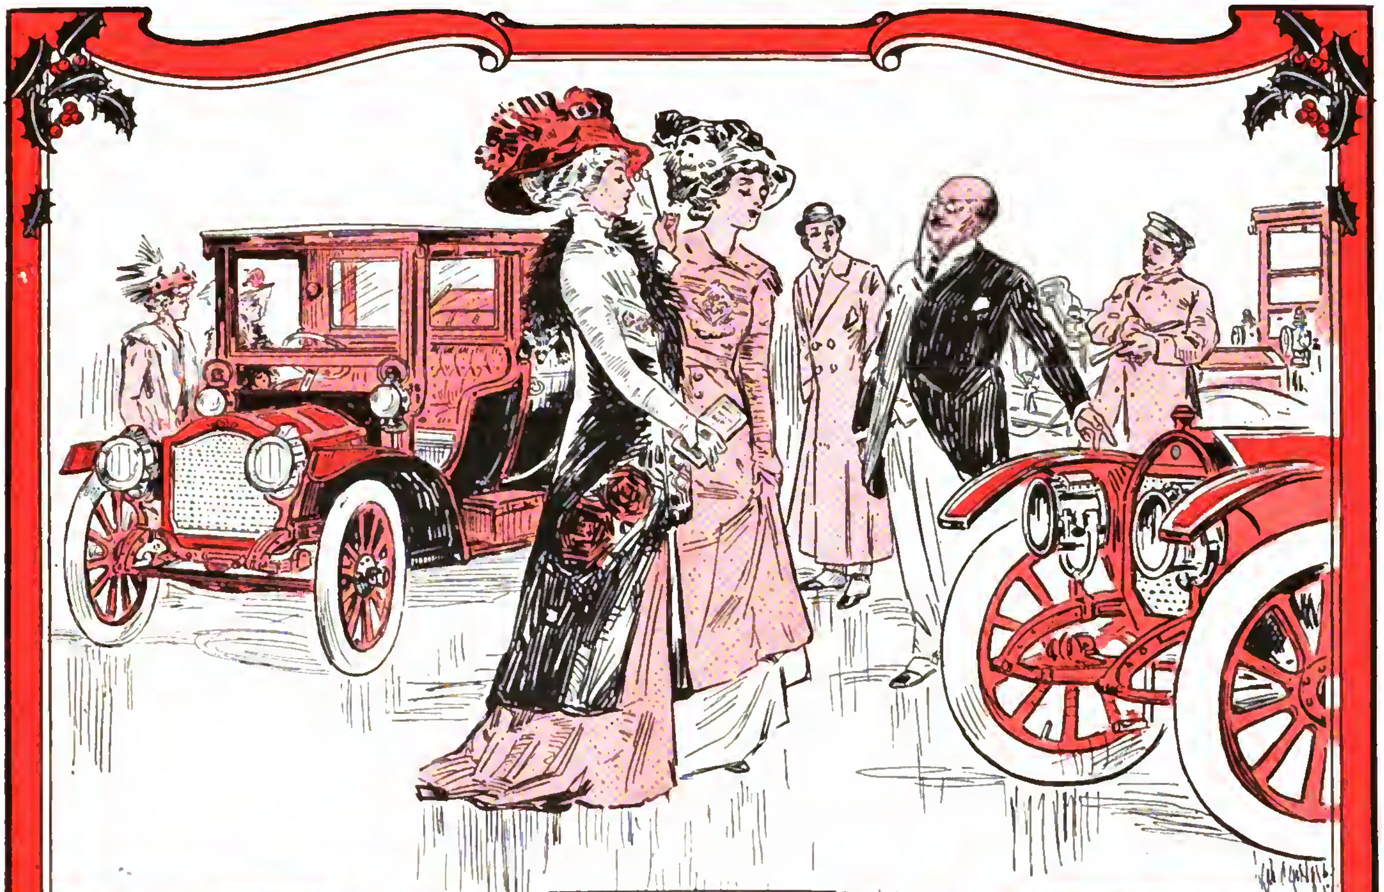
Vol. XXI NEW YORK—THURSDAY, DECEMBER 30, 1909—CHICAGO No. 27

The Automobile

First of New York's 1910 Shows

Under A. M. C. M. A. Direction in Grand Central Palace

Dec. 31 to Jan. 7



'Tis Hardest to Convince Woman

REPRESENTATIVE of the growth of a great industry in all its phases during the past year, the Tenth International Automobile Show of the American Motor Car Manufacturers' Association, opening in Grand Central Palace, New York City, on New Year's Eve, unquestionably will be the most varied and edifying assemblage of automobiles ever gathered under a single roof. Millionaire and mechanic will alike find the cars best suited to their requirements and pocketbooks. Engineers and technical men will find the contributions of a hundred creative minds to progress in this form of transportation.

So many have been the newcomers in the field, and so vast the estimates of the 1910 production, that rumors have been current of an inevitable overproduction and fall of prices. The show will dispel these ideas finally and conclusively. Instead of cutting last year's prices, most makers of medium-priced and cheaper cars have added from \$50 to \$200 to their former figures; and the indications are that Summer will see a shortage, rather than a surplus.

True, there have been more additions to the ranks of the manufacturers this year than ever before; but even if the whole industry could have exceeded the demands of the market, the increase defeated itself. The producers of parts and materials were left far behind.

As to the higher prices, this is but a reflection of the general trend, the "increased cost of living," of which so much has been said to so little purpose. Heretofore, reductions have been made in spite of this tendency. Quantity production and better sales organizations brought the familiar result seen in the case of the bicycle, but the utmost limit of economy seems now to have been reached. In many cases, however, the higher prices are not so high as they may seem at first glance, for many of the manufacturers have made changes in the direction of longer wheelbases, larger tires, bigger cylinders, and more complete equipment, which very nearly account for the apparent increase. Of every tendency in this direction, however, the show will offer a summary.

The international aspect of the show is of no small importance. Although the Importers' Automobile Salon numbers but twelve members, these all represent well-known foreign makes, and have been chosen by a strenuous process of the survival of the fittest. Thus it happens that the foreign cars exhibited are not only of the first class in their own country, but are established in the esteem of the American public. Not numerous enough to hold a show of their own, as they twice did in earlier years, the importers, nevertheless, add at least as much to the representative character of the show as they gain from inclusion under its roof.

Although many high-priced cars, both of American and foreign origin, are on exhibition, the Palace show will this year, as formerly, have rather a preponderance of medium and low-priced machines, of the distinctively popular makes. For this reason it draws a great number of automobile dealers, and also the carriage tradesmen who represent the more modern industry in small Western towns. Thousands of these will make their annual pilgrimage to New York to attend the show. The interest of the carriage trade is indicated by the request of hundreds of dealers for a repetition of the courtesies extended tentatively last year. As a result, invitations have been sent out to 2,500 carriage dealers rated at $50,000 and over, as well as to the 5,000 and more automobile dealers.

As a spectacle of the kind which attracts the general public and turns them into automobile enthusisasts, the show will be unrivalled. Exhibits to the value of over a million dollars, occupying 72,000 feet of floor space, and $30,000 spent on decorations, tell in brief the story. The Grand Central Palace, which on ordinary occasions is a far from prepossessing structure, and lacks completely the natural advantages of Madison Square Garden, has, by a supreme effort, been transformed into a dreamland of artistic beauty.

The color scheme and decorative effect is outlined by Nile green lattice work on a soft gray background of caen stone. The roof is a trellis arbor hung with grapevines, through which the sky is faintly seen. The decorations are set off by mirrors, electric fountains, and myriads of glistening lights. The real illumination comes from a number of alabaster globes of light hung by chains from the ceiling.

Attractive as are the decorations to every visitor to the show, the automobilists will, of course, be most interested in the cars themselves. The year's progress is well expressed in the 1910 models of the 84 exhibitors of complete machines. To describe, even to enumerate, the features of their design is a task of considerable magnitude. However, the lines of progress which all follow are well marked.

Simplification is the watchword. No single feature of design has been more generally adopted, nor has had wider influence, than the block cylinder casting. In several cases this casting includes not only the inlet and exhaust manifolds, but also the upper half of the crankcase. Nor has this made more difficult the part of the foundry, for the entire top of the water-jacket is now formed by a separate plate, so that the cores may be simple and have firm support. With this construction a single inlet and a single outlet for the cooling water suffice, and, with the thermo-siphon system of circulation, which is becoming general, two hose connections to the radiator give the minimum of incumbrance.

The real simplification embodied in these reforms is supplemented by an apparent simplification which is none the less praiseworthy. This generally takes the form of enclosing the valve stems and tappets by removable covers. Although the number of working parts remains the same, this enclosure gives the engine a neater appearance, lessens the noise, and keeps grit out of the many small bearings in the valve-operating mechanism. Lubricating systems are now generally contained in the crankcases of the motors, the simplification being sometimes real and sometimes only apparent, but always improving both the looks and the performance of the motor.

Transmission designs show increasing use of the two-unit principle; at least half of the exhibitors show the change-gear combined with either the motor or the rear axle. In fact, the struggle between these two forms is one of the most interesting features in the show. It takes the place of the old controversies between the magneto and the battery, and between automatic and mechanically operated inlet valves. One or the other will doubtless be adopted generally within the next few years, and those makers who have not yet tried them seem only to be waiting to see which fortune will favor.

There is a very noticeable lengthening of wheelbases and increase in tire sizes. Indeed, it is these changes which, in most cases, are the explanation of apparent raising of prices. However, the buyers of these cars more than get the value of their greater investment.

The A. M. C. M. A. show deserves the attendance of every automobilist in the country, whether he be builder, seller or buyer, or only "just interested." As an indication of the mechanical trend, its verdict is final; the practice of the American automobile industry as a whole is the practice of its exhibitors. As a business exchange, although the shows are not as prominent as formerly as a meeting place for makers and agents, it will, nevertheless, see no inconsiderable volume of business transacted. As a spectacle, for the attraction of the public and the interesting of future buyers, it is unsurpassed.

The List of Exhibitors

AMERICAN GASOLINE PLEASURE CARS

ALLEN-KINGSTON: Allen-Kingston Motor Car Co., New York City.
AMERICAN: American Motor Car Co., Indianapolis, Ind.
AMERICAN SIMPLEX: Simplex Motor Car Co., Mishawaka, Ind.
ATLAS: Atlas Motor Car Co., Springfield, Mass.
BELMONT: American Motor Co., Brockton, Mass.
BLACK-CROW: Black Mfg. Co., Chicago, Ill.
BRUSH: Brush Runabout Co., Detroit, Mich.
CAMERON: Cameron Car Co., Beverly, Mass.
CARTERCAR: Cartercar Company, Pontiac, Mich.
CHADWICK: Chadwick Engineering Works, Pottstown, Pa.
CHASE: Chase Motor Truck Co., Syracuse, N. Y.
COATES-GOSHEN: Coates-Goshen Automobile Co., Goshen, N. Y.
COLE: Cole Motor Car Co., Indianapolis, Ind.
CRAWFORD: Crawford Automobile Co., Hagerstown, Md.
DEMOT: Demotcar Sales Co., Detroit. Mich.
EMPIRE: Empire Motor Car Co., Indianapolis, Ind.
EVERITT: Metzger Motor Car Co., Detroit, Mich.
FAL-CAR: Fal Motor Co., Chicago, Ill.
FIRESTONE-COLUMBUS: Columbus Buggy Co., Columbus, O.
FORD: Ford Motor Co., Detroit, Mich.
GAETH: Gaeth Automobile Co., Cleveland, O.
GLIDE: Bartholomew Company, Peoria, Ill.
HALLADAY: Grant Sq. Automobile Co., Brooklyn, N. Y.
HUPMOBILE: Hupp Motor Car Co., Detroit, Mich.
INTER-STATE: Inter-State Automobile Co., Muncie, Ind.
JACKSON: Jackson Automobile Co., Jackson, Mich.
KISSELKAR: Kissel Motor Car Co., Hartford, Wis.
KLINE KAR: B. C. K. Motor Car Co., York, Pa.
LAMBERT: Buckeye Mfg. Co., Anderson, Ind.
LION: Lion Motor Car Co., Adrian, Mich.
McCUE-HARTFORD: McCue Company, Hartford, Conn.
McINTYRE: W. H. McIntyre Company, Auburn, Ind.
MARMON: Nordyke & Marmon, Indianapolis, Ind.
MAXWELL: Maxwell-Briscoe Motor Co., Tarrytown, N. Y.
METZ: C. H. Metz Company, Waltham, Mass.
MIDLAND: Midland Motor Co., Moline, Ill.
MIDDLEBY: Middleby Automobile Co., Reading, Pa.
MITCHELL: Mitchell Motor Car Co., Racine, Wis.
MOLINE: Moline Automobile Co., East Moline, Ill.
MOON: Moon Motor Car Co., St. Louis, Mo.
MORA: Mora Motor Car Co., Newark, N. Y.
NATIONAL: National Motor Vehicle Co., Indianapolis, Ind.
OAKLAND: Oakland Motor Car Co., Pontiac, Mich.
OHIO: Ohio Motor Car Co., Carthage, O.
OTTO: Otto Sales Co., Philadelphia, Pa.
PAIGE-DETROIT: Paige-Detroit Motor Car Co., Detroit, Mich.
PATERSON: W. A. Paterson Company, Detroit, Mich.
PENNSYLVANIA: Pennsylvania Auto-Motor Co., Bryn Mawr, Pa.
PIERCE: Pierce Motor Co., Racine, Wis.
PREMIER: Premier Motor Mfg. Co., Indianapolis, Ind.
PULLMAN: York Motor Car Co., York, Pa.
REGAL: Regal Motor Car Co., Detroit, Mich.

The Men Who Run The Show 1910

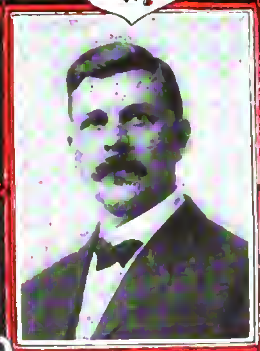
Benjamin Briscoe

Alfred Reeves General Manager

H. O. Smith.

S. H. Mora

David J Post



R. E. Olds, Chairman

E. R. Hollander

IN the conduct of what is announced as the "Tenth International Automobile Show," to be held in the Grand Central Palace from December 31 to January 7, past masters in the promoting of automobile exhibitions are numerous. Of course, the show is under the direct auspices of the American Motor Car Manufacturers' Association, but directly allied are the Importers' Automobile Salon and the Motor and Accessory Manufacturers, thus involving American cars and foreign importations, and accessories for both. R. E. Olds is the chairman of the 1910 show committee, and his connection with the automobile industry goes back to its inception in this country. Alongside of him is Alfred Reeves, the general manager, well known generally as the man who has done the most in making the A. M. C. M. A. a prominent factor in the automobile-making world. H. O. Smith, chairman of the committee of management of the A. M. C. M. A., needs no introduction, and another equally well known member of the show committee is Benjamin Briscoe, an ex-chairman and the predecessor of Mr. Smith. S. H. Mora has been an industrious committee member, and has earned his apparent permanent place. David J. Post is the experienced representative of the Motor and Accessory Manufacturers, and he has been a participant in expositions from the earliest days of the bicycle down to the present time, being one of those natural graduates into the motor-driven vehicle field. E. R. Hollander is the spokesman of the importers, and he was one of the pioneers of foreign cars in this country.

H. O. Smith, Chairman of the A. M. C. M. A. Committee of Management, contributes the following summing up of the situation:

Like the self-made man, the motor-car industry has forced recognition and respect. It is probable that no industry has ever started with so much to overcome. In the early days the financier's lack of belief and faith in the ultimate success was well-nigh universal. As the industry grew, the opposition of the banker seemed to more than keep pace. There are none so blind as those who will not see, and the persistent blindness of capitalists who secured their positions by their ability to foresee industrial developments was one of the most remarkable features of the automobile trade. But progress, development and demand could not be stopped—there was too much merit behind the proposition. While this was yet a struggling industry, seemingly floundering and groping in the dark for a guiding light, a statement was made by one who had doubtless made a study of the situation that it would take a panic to really develop the automobile industry. This statement has since proved almost prophetic, and the man responsible for the statement must be credited with unusual foresight, although he probably realized but little of the real truth this statement carried. The depression of 1907 measured the stability, strength and soundness of our country and every branch of trade, and it will be remembered that probably no other line held its own, while the automobile business continued to grow in spite of the would-be discouragement on all sides. Results have proven that there was little reason for the depression beyond the lack of confidence and belief that the general demand was not stable, and the remarkable part of it all lay in the fact that the most discredited industry at that time, the automobile, was the greatest help in averting a panic and restoring such confidence as was scarcely hoped for. The fact that the automobile business would not be kept down caused the thoughtful to pause and consider. Why the remarkable record?

Saving of time and lessening of distance are two important factors in our modern civilization. The motor car is the great agency which has met these requirements in a practical way, and to a degree never dreamed of, and it possesses a third and important virtue of being able to do this at a very marked saving in cost. It is the going motor car which has forced recognition, and it is to-day quite as indispensable as the telephone, telegraph, or railway train. It is safe to predict that we have not more than scratched the surface of the possible demand for the motor propelled vehicle. The motor car was first looked upon as the rich man's and the sportsman's toy—later, as a pleasure vehicle to be classed as a luxury, but to-day we are forced to admit that it is the practical conveyance of the future. It would be quite as reasonable to expect the transcontinental traveler to return to the prairie schooner as for the motor-car user to return to the horse-drawn vehicle. In fact, the step from the horse-drawn vehicle to the motor car is quite as advanced as turning to the use of the railway cars, except that the use of the motor car is brought home to us in a more general and telling way.

Many do not to-day realize the firm way in which the motor car has established itself. To the physician, the contractor, in fact, to any man who finds it necessary to be in divers locations in the ordinary routine of work, they prove indispensable, and as yet we are only beginning to understand the possible uses a motor car can be put to advantage. We have seen an industry spring up in a night as it were—and move from nothing to a position of probably fifth in importance among the great industries of this country, and in the brief period of less than ten years. We are only beginning to realize the scope of this modern agency of progress, and it is impossible to measure its ultimate influence and usefulness.

There is another and interesting phase. It has been said that the motor car in France affords employment for more people than any other line, and in America we are employing directly and indirectly more people than they are. It has set a new mark in the consumption of rubber. It requires hundreds of thousands of hides per year for upholstering. It is safe to say that the motor car builders are furnishing the greatest number of orders placed with our machinery builders, and the development of the most modern device to facilitate production and standardization is directly attributable to the motor car builder. They have been directly responsible as well for the development of high class anti-fatigue steels. So that it can be seen that the motor car has not only been forcing recognition, but its requirements have reached out in various channels until it has become a great factor in the labor market and materials of various sorts and kinds.

Alfred Reeves, General Manager American Motor Car Manufacturers' Association, tells why the building of motor cars is now a national industry:

Automobile making is now a national industry and on a par with any other line of manufacturing in America. This is best evidenced by the Tenth International Automobile show which will open on New Year's Eve, when 325 exhibitors will show products from every nook and corner of the United States. That the industry is national is proved too by the statistics showing the millions of dollars of capital involved, the thousands of cars made and sold, and the thousands of employees of automobile and automobile parts factories. Figures that are conservative in every way make it appear certain that 200,000 motor cars are scheduled for 1910. They will be made in 21 different States by 263 makers located as follows:

Michigan	49	Wisconsin	6
Illinois	39	New Jersey	4
Indiana	30	California	4
Ohio	30	Rhode Island	3
New York	23	Nebraska	2
Pennsylvania	18	Maryland	2
Massachusetts	14	Colorado	1
Missouri	12	Nevada	1
Connecticut	10	Texas	1
Iowa	7	Kansas	1
Minnesota	6		

Of this number it may be said that 100 are legitimate makers, turning out cars that are factors in the market. Seventy-five others produce less than 75 cars each, and are little heard of, while the remainder may be considered beginners whose products may not get beyond the experimental state. New York, for example, although credited in the above official list with 23 makers, has not more than seven substantial automobile factories.

Taking 80 of these leading makers and compiling their estimates for 1910, coupled with the reports from the parts makers and the inspection made while visiting 62 prominent factories last Spring, shows that the 200,000 cars for next year will be divided primarily among the five States.

Michigan is king, for in 1910 it will produce not less than 102,000 motor cars. Illinois will turn out 15,300; Indiana, 21,025; Ohio, 22,750; Wisconsin, 11,000; New York, 10,400; Massachusetts, 4,100; Pennsylvania, 3,250; Connecticut, 2,100.

When it is taken into consideration that the capital involved is between $150,000,000 and $175,000,000, that there are 5,200 agents for motor cars throughout the country maintaining garages and salesrooms, the whole employing more than 200,000 employees, no one can deny that the making of automobiles is now one of America's most important industries.

With the rapid growth of the automobile industry there has been a general improvement in the good-road system throughout the country, a general increase in business among hotels and roadhouses, and a general increase of trade among the hundreds of concerns that supply parts, materials and accessories for the motor car and its followers. In fact, one of the most remarkable features of this new branch of manufacturing is the innumerable ramifications through which it has interwoven itself into the commercial system of the country, influencing directly or indirectly the lives of many millions.

Considering automobile making as a national industry, it is worth noting that the National Grange, the big aggregation of farmers with a membership of more than a million, is advocating the passage of a Federal good roads bill having for its purpose national aid for roads throughout the country. This is in line with the national idea that the building of roads should be encouraged by the national government, and appropriations made for that purpose, the same as for rivers and harbors. The farmer has always been an important factor in road improvements, and now that he is using the automobile, he is a stronger advocate that ever—all tending toward the recognition of motor car building as a national industry.

PROGRAM OF PALACE SHOW WEEK

Friday, Dec. 31, 3 P. M.—Private view for members Automobile Club of America, American Automobile Association, Long Island Automobile Club, and city officials; 8 P. M., formal opening of show to public.

Saturday, Jan. 1—Show open from 9 A. M. to 10.30 P. M. Smoker at Automobile Club of America to Grand Central Palace Show exhibitors; "Army and Navy Night."

Monday, Jan. 3—New York Automobile Trade Association meeting. Manhattan Hotel, 12 o'clock; "Engineers' Night."

Tuesday, Jan. 4—Society Day, admission $1; 10 A. M., annual meeting of Society of Automobile Engineers at Automobile Club of America; 8 P. M., dinner of Society of Automobile Engineers, Automobile Club of America.

Wednesday, Jan. 5—Meeting of the Good Roads Board of the American Automobile Association; 6 P. M., annual meeting of Motor and Accessory Manufacturers, at Waldorf-Astoria Hotel, followed by banquet at 7:30 o'clock; "Merchants' Night."

Thursday, Jan. 6, 2 P. M.—Meeting Committee of Management of American Motor Car Manufacturers' Association; 7 P. M., Dealers' dinner given by Maxwell-Briscoe Motor Company, Hotel Manhattan; "New York Night."

Friday, Jan. 7—First annual meeting of Manufacturers' Contest Association, Manhattan Hotel; President Benjamin Briscoe will preside.

Tables Which Tell a Condensed Story

TENDENCIES in every branch of the industry can never be expressed so completely or in such compact form as in a good table of specifications. When every separate detail of the cars is brought into a single column a glance suffices to tell which form of construction preponderates. At the same time such a table may be regarded as an encyclopedia of automobile knowledge, from which one can determine at a moment's notice the salient features of a given car.

As the price is generally the first thing considered for any car, the price column immediately follows the name. Ordinarily the price given includes an equipment consisting of the necessary tools, five lamps and a horn. There is a growing and laudable tendency, however, to make the price include a Cape top and often a wind shield. Whenever the top is included in the given price, that fact is indicated by a dagger (†). In several of these cases a wind shield is also included, but it was not found practicable to distinguish this also.

Horsepower ratings are in all cases those given by the A. L. A. M. formula, disregarding the maker's rating when it differs from this standard. It is plain that this is the only fair way to rate for comparison a number of different cars, and this rating has the additional advantage of showing at once the comparative cylinder sizes of the foreign cars, which are measured in millimeters. No attempt has been made to rate two-cycle motors, as the formula was never intended to cover these. Rather than give arbitrary figures, therefore, the horsepower spaces of two-cycle motors have been left blank, except for an asterisk (*) to indicate that the omission of figures was intentional.

The columns following these, containing the type of body, the number of passengers (or, for commercial cars, the load in tons) will be self-explanatory. The types of bodies variously designated as toy tonneaus and pony tonneaus are all grouped as baby tonneaus. When a number of different body styles are fitted on the same chassis, the touring body alone is given. The rule has been to give each separate chassis one line, without regard to the number of bodies which are interchangeable on it.

Various systems of lubrication are in use, and it has not always been found possible to distinguish between these as sharply as might have been desired. In general, those systems in which the oil is circulated and used over and over are designated by the word "pump." Those cases in which several pumps are used for forcing the oil to bearings or cylinders, the oil often being expected to splash about in the crankcase, but not being used again, are designated as "mechanical" by the abbreviation "mech." preceded by a figure indicating the number of such feeds. The "splash" systems are those in which a quantity of oil is injected into the crankcase by the driver, different methods being employed of assuring that it reaches the cylinders and bearings.

The location of the change-gear box is indicated in the column following that describing the gear. The word "motor" means that the box forms a unit with the motor; "frame," that it is a separate unit supported from the main frame; "shaft," that it is on the front end of the propeller shaft, just behind the universal joint; and "axle," that it forms a unit with the rear axle. In the next column the word "shaft," indicating that the car is shaft-driven, is followed by a figure "1" or "2," denoting the number of universal joints in the drive shaft. This gives a good indication of the axle construction, as when but one joint is used the shaft is always surrounded by a tube which is used to take the torsion strains from the axle.

For the convenience of Southern automobilists, those cars which are made with the Southern standard 60-inch tread as an option to the regular standard are marked with a double dagger (‡) in the column giving the tread.

UNDER $1,000

$485	Brush	Runabout
500	Reo	Runabout

FEATURES OF TENTH INTERNATIONAL SHOW

Opens New Year's Eve.

Three hundred and twenty-five exhibitors.

Value of exhibits, $1,100,000.

Lowest priced car, $378.

Highest priced car, $10,000.

Expected attendance, 110,000.

Seventy-two exhibits of leading American cars.

Twelve exhibits of foreign cars.

Seventeen exhibits of commercial vehicles.

Fastest American light car, Maxwell.

Fastest foreign light car, Lancia.

Fastest American car, National.

Fastest foreign car, Fiat, 102 miles an hour.

Number of square feet exhibition space, 72,000.

Expected attendance of carriage dealers, 1,500.

Expected attendance of automobile dealers, 4,000.

Thirty thousand dollars expended for decorations.

Exhibit of famous racing trophies, including Grand Prize Gold Cup.

Acceptance from public officials for private view, 3 p. m. December 31, army and navy night, engineers' night, merchants' night and New York night.

Show open from December 31 to January 7, except Sunday.

Decorative scheme, trellis garden effect with 10,000 electric lights, plate glass mirrors, electrical fountain, porte cochere, paintings, palms and potted plants.

Show under management of American Motor Car Manufacturers' Association, with Importers Automobile Salon and Motor and Accessory Manufacturers.

Headquarters during week for American Automobile Association, New York Automobile Trade Association, Bureau of Tours of Automobile Club of America and American Motor Car Manufacturers' Association.

Reasons Why One Should Buy

AMERICAN SIMPLEX: George S. Waite, Sales Manager—Suppose you could remove from the four-cycle automobile engine you are interested in, all valves, guides, springs, noisy front gears, and the other complications incidental thereto and add immeasurably more power, would you not consider that you had radically improved the car, and increased your motoring satisfaction?

You cannot, of course, nor can the man that designed it. But that is exactly what we do in the American Simplex. We eliminate these objectionable working parts and dismiss forever the four-cycle "bugbear," intermittent power.

In design and mechanism, it meets the certain approbation of every engineer who inspects it. In construction, it is sturdy and powerful, adhering to a high standard with a painstaking attention to the most minute details, possibly only in a thoroughly equipped factory and under the supervision of a competent engineering force.

In a word, a manufactured, not an assembled car.

We possess the unqualified endorsement of American Simplex owners all over this broad continent, and in the multitude of counselors there is safety.

If the foregoing statements are correct—and we invite corroboration—there is no reason why an automobile buyer should not purchase the American Simplex motor car.

ATLAS: P. A. Williams, Jr., Sales Manager—The average automobilist to-day demands safety, comfort, silence, style, power, fair speed, simplicity, durability and low maintenance charge—and usually a fair price. The Atlas combines all of these features to a greater extent than any other car.

First.—Safety. Every part of the engine and car is made of the best quality of material—thoroughly tried and tested under severest conditions.

Second.—Comfort. Experience has shown that the three-quarter elliptic spring now being generally adopted and first used in this country on the Atlas cars gives the easiest riding car, eliminating all side sway of the platform springs—the springs of the Atlas are extra long, three-quarter elliptic, made from imported Krupp silicomanganese steel, the best material known for this purpose—which, combined with the long 128-in. wheelbase, gives a car which for comfort has no superior.

Third.—Silence. The absence of external moving parts makes the engine the quietest engine running.

Fourth.—Style. Atlas cars are classy in lines, are highly finished and handsomely upholstered in hand-buffed leather with every convenience and comfort.

Fifth.—Power. The Atlas 60-horsepower engine is the highest-powered engine put into a medium-price car; furthermore, this power is developed at an engine speed of twelve to thirteen hundred revolutions, giving an available power in the hands of the ordinary user for general work and hill-climbing.

Sixth.—Speed. This power gives ample speed for every class of work.

Seventh.—Simplicity. The Atlas engine is the simplest engine built—a crankshaft and two moving parts to each cylinder.

Eighth.—Durability. The Atlas engine will outwear any other automobile engine built. The crankshaft is hardened, ground and polished; the bearings and shaft are indestructible under ordinary conditions and engine parts replacements are unknown.

Ninth.—Low Maintenance. The absence of replacement makes the maintenance cost the lowest.

Tenth.—First Cost. The price is several hundred dollars less than any other car of equal power and quality.

BLACK-CROW: C. C. Darnall, Sales Manager—The all-important reason why a buyer should invest in a Black-Crow car is that by so doing he can get all of the important features, up-to-date improvements, and standard equipment known to the present-day automobile manufacturer at the astonishingly low price of $1,000, within the reach of everyone.

The 107-inch wheelbase affords ample leg room in the body, greatly benefits the riding qualities and gives the car a big appearance. The motor is assembled en bloc with a five-bearing crankshaft, and runs absolutely noiseless. The constant level self-contained splash lubrication system, in connection with a plunger pump, is a late improvement. The multiple-disc clutch, containing a sufficient number of large steel discs and a heavy spring, permits of gradual engagement and is perfectly dependable.

Large honeycomb-type radiator, in connection with spacious water jackets, forms an ideal cooling system. The Remy magneto furnishes a desirable current supply and ignition system. The straight-line shaft drive, in connection with a single universal joint and rear axle transmission, is a construction that is rapidly coming to the front. The selective-type sliding-gear transmission requires no comment. There is not a gear in the transmission of less than ⅞-inch face. The gears are set on square shafts instead of being fastened with keys and the shafts run on Hyatt high-duty roller bearings. Hyatt-roller bearings are used throughout with the exception of the front wheels, which turn on two-point balls.

Control, consisting of two foot pedals, two hand levers and a large steering wheel with spark and throttle control on top of wheel, is just the same as that found in nearly all high-priced, high-grade cars.

Taking the car as a whole, it is a nicely finished, neat appearing, easy riding, smooth running and perfectly reliable machine.

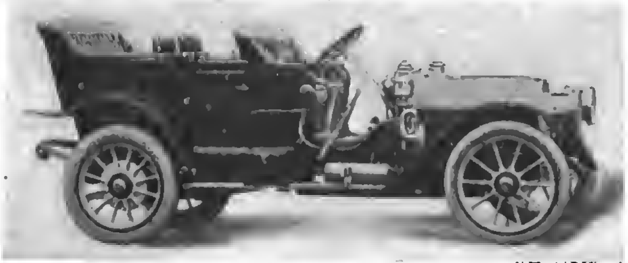
BRUSH RUNABOUT: Brush Runabout Company—Perhaps there is no other automobile which fills the peculiar position of the Brush Runabout. It has been called "everybody's car"; properly so, in view of its general utility, it being used, for illustration, in the plant of the Chalmers-Detroit, for messenger service, delivering material and the dozen and one things for which a serviceable car can be employed around a big plant, and in the doing portrays a condition which should be readily appreciated, *i. e.*, the Brush is a serviceable car, free from complication, easy to start, sure to go, and devoid of annoying complication.

The design of this car differs from the underlying scheme of the average small car, in that it is not a study of some ponderous touring car; it is especially contrived in every particular to serve a utility end. The style and finish of the car, while differing, may be regarded nevertheless, as satisfying, and in road work, whether in pleasure or utility pursuits, the car has proven out. The best argument that can be advanced for the Brush then, all things considered, is that it is selected for every class of use by buyers of acumen, and it is being sold by the thousand, after wide opportunity to find out its qualities, the prime idea being that it is a nimble serviceable automobile.

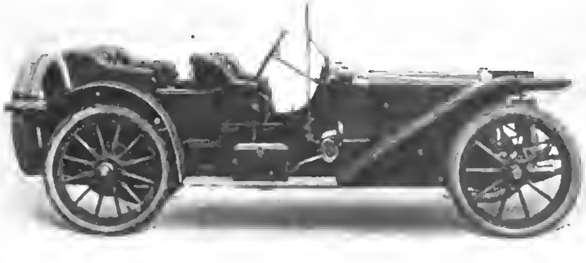
CARTERCAR: W. H. Radford, Sales Manager—The reasons a prospective automobile purchaser should buy a Cartercar are that it will give a maximum amount of service, at a minimum cost in expense and trouble, for the longest time, in the hands of an ordinary user. The car will climb a 50 per cent grade with a full load and will plough through mud holes and sand spots which stall other cars.

Reasons for this are that with a friction transmission, any number of speeds are obtainable and the same ratio of motor power is delivered to the rear wheels on the lower speeds as is delivered on high. Opposed to this, the lower speeds on cars with geared transmission consume a much higher percentage of power when it is needed the most, as in sand, on hills, slippery streets, etc.

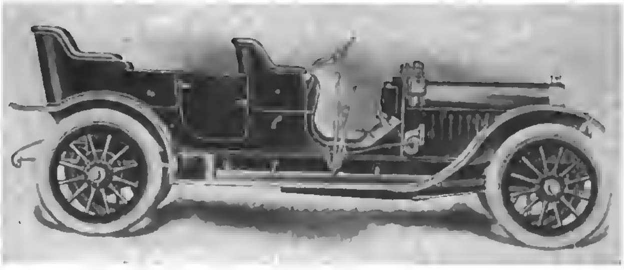
The chain-in-oil drive is practically noiseless and does not require attention except in adding a little lubricant from time to



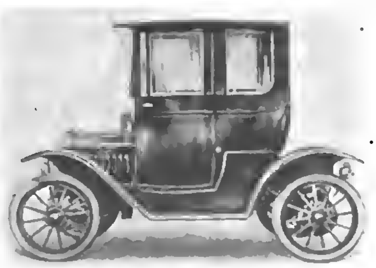
American Simplex Two-Cycle, Four-Cylinder 50-Horsepower



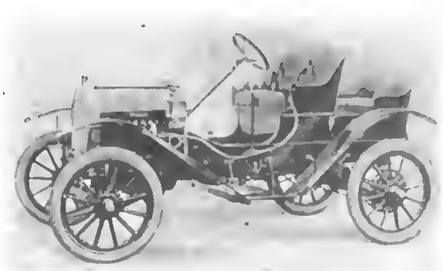
American Traveler Four-Cylinder 50-Horsepower



Atlas Two-Cycle, Four-Cylinder 60-Horsepower



Brush One-Cylinder, 10-Horsepower Model D Coupe



Brush One-Cylinder, 10-Horsepower Model D Runabout

time. An inexperienced driver could operate the Cartercar without injuring the mechanism. The single-lever control avoids the possibility of confusion in operating the car. There is no clutch to slip—no gears to strip—no grease packing—no universal joints—no shaft drive and no bevel gears. Surely a car which is a complete success with these omitteed is a good proposition.

On crowded city streets or rough roads any lower speed could be dropped into with ease and there will be no grinding of gears or racing of the motor.

This car is built along the latest approved lines, has style and snap, is roomy and elegantly finished. The equipment is complete and the value is real.

CHADWICK: M. H. Adams—The Perfected Chadwick Great Six to-day presents a strong appeal to the prospective customer because of a mechanical construction original and distinctive and small details producing a complete and harmonious whole, tending to fulfill every function that would prove desirable in an ideal car.

The control of the car is of wonderful flexibility, cars throttling from seventy (or better) miles per hour on direct, to five, without the slightest skipping or irregularity of running in the engine whatever. The carbureter, the engine control, the clutch, the steering gear, the transmission and the entire driving mechanism of the car have been designed with special reference to ease of handling both at high and low speeds.

It is only by the employment of exclusive designs that many of the serious faults in motor-car construction have been overcome. While ease of control in a high-powered motor car is a luxury, ease of riding qualities is even more so, and the use of a peculiar type of spring design and flexible chain drive, with the correct proportioning throughout the entire car, give ease of riding qualities which are unsurpassed, and are of the very utmost importance in any car capable of high speeds.

Durability as a factor has been carefully considered and worked out after many years of experience. The employment of correct engineering design, the use of the highest quality of special materials, the maintaining of an organization whose standard is the very highest quality of workmanship, have produced to-day a car capable of enormous mileage with minimum upkeep. In any motor car the factor of safety to the individual, the assurance against expense from defective design or material are of the utmost importance. In the Chadwick car are not only embodied that quality of material and workmanship that is a positive guarantee of safety, but throughout it contains details of design and construction which are designed solely with reference to protection against accidents.

On this car the entire steering mechanism is to-day the most carefully designed of any car in the world, and the same attitude is carried throughout the entire chassis. As a rule, a car strong in mechanical design and construction does not have body designs of equal attractiveness, but in the Chadwick car the body designs are beautiful, graceful, and each and every detail of body design is correct in every particular and will satisfy the most discriminating purchaser. The Perfected Chadwick Great Six is to-day offered as the production of an organization whose only aim is to build the very best.

CRAWFORD: Geo. D. Crawford, Treasurer—The following qualities should influence a careful buyer of an automobile to select a Crawford: It possesses the power requisite to a satisfactory car, not only sufficient to enable it to carry its load swiftly and smoothly over the ordinary road, but reserve force equal to all road emergencies.

This power is transmitted through gears made of special grade of nickel steel, tested to stand the greatest strain.

The Crawford will commend itself by its practicability and simplicity of design, eliminating complications, fads, and fancies in mechanism, reducing loss of power from friction to a minimum, and by its beauty of outline, perfection in finish, comfort in riding, and further, in that it offers the highest intrinsic value.

EMPIRE: J. G. Wood—Empire cars were designed to meet the requirements of the man who desires to purchase a car of not only low first cost, but low maintenance cost, realizing that a large per cent. of the maintenance cost of a car lies in the wear and tear of the tires. The Empire cars are built with this primarily in view.

Contrary to the average practice of making small cars extremely light, the Empire Company has added weight where they thought it was necessary. For this reason such parts as axles and parts of the driving mechanism are unusually heavy, in fact as heavy as many of the medium-sized touring cars.

The car is extremely easy riding on account of its spring suspension, which consists of four-sided platform springs in the rear and three-quarter elliptics in the front. This in conjunction with a double sidechain drive practically eliminates undue tire wear, also relieves all excessive strains from the frame and driving mechanism. The double sidechain drive is very neatly installed, the chains being run in pressed-steel housings so that they are absolutely noiseless and give no trouble whatever.

Tire equipment is rather unusual for a car of this price, 32 by 3 1-2 inch size being used all around, q.d. rims being furnished as regular equipment. The car is also equipped with a Remy dual ignition system.

In brief, the Empire cars are extremely well adapted to the use of doctors or salesmen who must take into account the maintenance cost of a car.

GAETH: L. E. Stone, Secretary—We would present the following arguments to convince a prospective purchaser that the Gaeth car suits his purposes:

In the first place our car is the simplest standard, four-cylinder car in every respect now being manufactured.

In addition, due to our limited output each car is constructed, tested, and inspected under the personal supervision of our designer, Paul Gaeth.

Third, our car is equipped with make-and-brake ignition which has proven unique in its simplicity and reliability, and besides is the only make-and-break ignition which will start on the spark in the same manner as the high tension.

Fourth, our thermo-syphon system of cooling has been brought to such a state of perfection that we have absolutely no trouble in cooling our motor under any circumstances of usage. This system eliminates the necessity of a pump with its troubles.

Fifth, the greater part of our car is manufactured and finished in our own shops.

Sixth, we use every effort to make our car as well finished in all details as any machine upon the market, irrespective of price.

Our machine is constructed of the best obtainable materials, and in such a manner that there can be no question as to its long life, durability and satisfaction.

GLIDE: R. A. Whitney, Sales Manager—In presenting the 1910 Models of the Glide to the public, we shall continue to stand on the platform of "Quality" backed up by a long and growing list of satisfied users scattered over the entire United States.

Our nine years of experience in manufacturing Glide cars has been a constant progress of eliminating weak points and substituting those features which have been found worthy, until the Glide stands to-day fully standardized, perfect in detail, and offers a full dollar of value for every dollar of price asked.

The Glide has pioneered many of the basic features now used successfully by some of the best American cars and we cheerfully invite comparisons, irrespective of price.

We have found no radical changes necessary in our 1910 Models, such changes being rather in refinement of detail and finish. The body lines have been refined, weight reduced, frame and body lowered without reducing the road clearance, larger tires and a straight-line drive, steering wheels are larger and all woodwork of Circassian walnut. The 1910 Glide has a dozen other features, every one of which are real improvements.

We guarantee satisfaction. We guarantee every piece and

part of a Glide car for one year free of defective material and imperfect workmanship, and will make good if such a piece is found.

Glide cars are now built throughout in our own shops, and with our new factory giving us 85,000 square feet of additional floor space, we feel the Glide is just entering on a new era of prosperity and that we are in a better position than ever before to make prompt deliveries and meet the demands of our agents and customers.

HOLSMAN: George E. Sherman, Advertising Manager—If you are looking for a practical, every-day-in-the-year car, that will negotiate all kinds of roads in all kinds of weather, you should buy a Holsman, because of its:

1. Solid Tires—which eliminate the enormous cost and trouble attendant upon the use of pneumatics. The high, flexible wheels make easy riding.
2. Simplicity—No differential. No transmission gears. No clutch. Easy control.
3. Direct Drive—from motor shaft to wheels on all speeds.
4. All-Ball-and-Roller-Bearing Motor—friction bearings and connecting rods being entirely eliminated.
5. Superior System of Lubrication—gasoline solution.
6. Economy of Up-Keep—on account of small number of parts.
7. Durability—many Holsmans have been in daily service six and seven years.
8. Hill-Climbing Ability—look up our Algonquin hill-climbing records. The direct drive, the high horse-power as compared to the weight of the car, and the application of that power near the outside rim of the rear wheels (where the greatest leverage is secured) make the Holsman able to go through sand, snow, slush and mud and up any hill ordinarily traversed by horse-drawn vehicles.

HUPMOBILE: R. C. Hupp—The real reason that the manufacture of the Hupmobile was decided on was the direct result of the experience the writer had in the production of cheap cars. In years gone by it has been assumed that as a man did not pay a high price for an automobile he could not expect to have it stand up. The cheap cars were always spoken of as being very good cars "for the money." In a great many cases these cheap cars were of pretty good size; in fact, they nearly always were heavy. The cheap cars without exception had planetary transmissions and used dry cells for ignition.

A small car was therefore mapped out by us in which we incorporated only the very best material. Our drawings specified close work, and the result was that we found we could build a small car of the highest grade at a low price. We discovered one thing absolutely, and that is that the bigger the automobile that is made right, the more it will cost. By placing our seats well back and using a patented spring suspension we found that we could carry two large people to the very best advantage. After having produced one thousand cars we find that this car has opened up an entirely new field in the automobile business. It has absolutely dissipated the former idea that a small car cannot be made well. and appeals, not only to people in moderate circumstances, but has become very popular with those who maintain large cars and wish the small car for general use.

INTER-STATE: C. E. Easton, Advertising Manager—Principal among the reasons why a man should buy an Inter-State car is the fact that we started in the automobile manufacturing business at a time when motor car practice had become standardized, and we incorporated in our first models only those features which had been tried out and found satisfactory.

The most important reason for our ability to give greater value is that the reliable features which have been developed by countless experiments made by the motor car trade were at an enormous cost to themselves. By embodying these features in our first models it enabled us to give more motor car for the money than even the older manufacturers.

Then in our new models we have further refined the high standard of design, material and workmanship, making it a high-grade car at a moderate price. These refinements consist of more power, longer wheelbase, adoption of three-quarter spring suspension, rolling push rod contact, multiple disc clutch of 63 tempered steel plates and 6 springs, eliminating the possibility of the weakening of a single spring construction.

A unit construction is carried out from the point where the power leaves the motor to the rear wheels. This transmission and axle system is practically as strong as if the complete system were one single casting or forging, as all connections and flanges are designed to give the highest factor of safety possible.

The transmission is especially interesting from the fact that the clutch and gear set are contained in a single aluminum case. The gears are of vanadium steel and are one size heavier than have ever been used before. This eliminates wear and breaking of gears, but does not decrease the ease of shifting, as all engaging teeth are chamfered with an improved curve.

Other features of particular importance are the centrifugal pump integral, with crank case; the rotary gear oil pump outside of crank case, giving perfect accessibility; the high tension imported U & H magneto. All of this equipment is located on one side of motor and driven by one shaft, the simplicity and perfect alignment of these parts being at once apparent to any one lifting the hood.

Last, but not least, a perfect interchangeability of parts. This is accomplished by our almost perfect machine tool equipment, as at the time of installing these machines the machine tool trade had produced automatic machinery especially adapted to automobile manufacture.

JACKSON: Jackson Automobile Company—From the agent's point of view, the Jackson offers attractions, among which a line of cars covering the requirement, most thoroughly, there being 50, 40, and 30 models, and the "30," which is intended to be a popular car, has a magneto in the ignition system as well as many other refinements, which, but a year or two ago, would have to be searched tor in high-priced "foreign" automobiles.

Then, in Jackson cars, of all models, there is a certain harmony from the engineering point of view, which, for that matter, would be of small avail were it not for the Jackson policy of having in the shop a wholesome respect for the intentions and demands of the engineers who lay out the cars. But, even good intentions, in the absence of good facilities, would count for naught; in the Jackson plant, as well as fine machine tools with which to do the work, there is a wide equipment for use in drop-forging the parts, and with this equipment, attended by a heat treatment department of competence, the engineer has but to say the word and he may have anything he indicates.

Prompt delivery, if it does not mean hurry, is worth more than a little, and, in the Jackson plant, in view of the scope of facilities offered, there is ample evidence of ability to deliver without having to stint the process. Materials, such as should be used in automobile construction, are available in the Jackson storeroom in quantity sufficient and to spare. The purchasing department, acting in conjunction with the engineering department, settled this important matter many months ago, and purchasers, as well as agents, are now in a position to reap the reward. Jackson results is what they will get, and the Jackson reputation is not at stake.

KLINE KAR: William P. Seig—The Kline Kar 40-50-horsepower car is the best offering at anything near its price because it is the only six-cylinder motor with en-bloc system, a bearing between each cylinder and each cylinder removable, one independent of the other, and includes in its specifications: 36-inch wheels, 122-inch wheelbase, three-quarter scroll elliptic springs, selective sliding gear transmission, two separate systems of ignition, including Bosch magneto, and single unit coil with switch located on the steering column, flat tube cellular radiator,

11-inch road clearance, full floating rear axle, "I" beam front axle, high-grade finish, best grade hand-buffed leather upholstering.

Rushmore lamp equipment, straight line body, the lines carried out inside the tonneau, giving ample room for the occupants, thus eliminating cramped positions. The dash, hood strips, rim on steering wheel, coil box, strip on top of tonneau doors are all made of Circassian walnut, alloy of steel used throughout, and, in fact, everything installed in the car is the best that money can procure and skilled mechanics can manufacture.

McINTYRE: George F. Lemon, Sales Manager—Having been asked why a man should buy a McIntyre, the writer would like to know in return why a man should *not* buy a McIntyre. Never having been in the market for a motor car, we may not have the correct viewpoint, but it would seem that a purchaser of one would be largely governed by the same principles that apply in the purchase of any other article. Most purchases are made, we think, from the buyer forming the opinion that the article he is purchasing possesses merit to a greater degree than competing articles, thus putting the article to be purchased on a comparative basis.

There are no secrets about motor car construction. The materials which enter into such construction may be bought in such quantities as may be desired (if one is lucky and places one's order far enough in advance), and of such varying degrees of goodness as may be desired. No one manufacturer has a monopoly of labor, skill, or brains, consequently it would seem that the production of a good motor car would be dependent (as is most other lines of manufacture) upon the tendency of the manufacturer to give the most in quality and quantity for the money.

We have assumed that we could manufacture a four-cylinder motor car and sell it for $1,400 which would embody every detail of simplicity, comfort, and quality. And in designing the McIntyre 30 we have borne in mind all that has been accomplished by other manufacturers—and, as stated before, there is no uncertainty as to what constitutes goodness in automobile construction. For instance, it is pretty generally conceded that transmission gears, etc., shall be made of a certain quality of nickel steel, that an open-hearth steel, free from phosphorus, silica, etc., and running rather high in carbon, makes the best crankshafts; that a wheelbase of at least 112 in. is necessary to have an easy riding car; that 36-in. wheels are better than 32 in., and so on.

In offering the McIntyre 30 we are offering a car which possesses absolutely every feature possessed by any five-passenger car, except that of extreme speed—so we would like to know why shouldn't a man buy a McIntyre, when by so doing he can save anywhere from $300 to $1,000 and get everything that is to be had at any price, except great speed, in a five-passenger touring car.

We know this is a mighty broad statement, but we say it advisedly and with a full understanding of its meaning in every particular. A great many men who know something of motor car construction have asked the writer how we can give so much car at the price. There is a reason, of course, but it is another story. Suffice it to say that we do it. While this refers particularly to the McIntyre 30, it is also true and to the same extent of the McIntyre 20 at $600.

Again we ask, why shouldn't a man buy a McIntyre?

MARMON: Nordyke & Marmon Company—The Marmon "Thirty-two" is moderate in size, power and weight—consistent in price. Designed and manufactured entirely by a concern of sixty years' manufacturing experience, whose products enjoy a world-wide reputation second to none.

This Marmon car is manufactured from the best materials obtainable, and the workmanship is of the highest order. The proof of this is apparent to any one who will take the trouble to see for himself by visiting the factory. It is the easiest riding car in the world—those who own it say so; so do those who ride in it. It is easy on tires, because it is properly proportioned in weight with reference to power and capacity. It has a simple, economical and unfailing oiling system—a system found only in the Marmon car. The brakes are more than adequate. The rear system is simple, clean-cut and very accessible. The body is of cast aluminum and steel—far more substantial and better finished than usual.

The stability of the car has been proved beyond question by its success in the hands of users, and notably by its showing in Glidden tours and many endurance contests, and by winning many long races on track and road.

MAXWELL: C. W. Kelsey, Superintendent of Sales—All automobile salesmen are alike in that they are naturally prejudiced in favor of their own article and see their competitors' goods only in a distorted way, magnifying their faults and minimizing their good points, so that it is hard for a prospective customer to get honest opinions. Owners are likewise biased in favor of the cars that they have; thus the buyer, oftentimes handicapped by the lack of mechanical knowledge, is in no position to judge, and buys the car handled by the best salesman.

Now, in order to reach all classes of customers and to avoid, so far as it is possible, these natural prejudices, we will compare our car with those high-grade, high-priced American machines which on American roads and under American conditions stand to-day pre-eminently in the highest ranks, namely, with the Packard, Pierce and Peerless.

Take, for instance, the Maxwell motor. In general design it is almost exactly like all of these. The cylinders are of the T-head vertical type, with the valves on opposite sides interchangeable and mechanically operated, and cast from gray iron. On all of these cars this type of cylinder is used. The crankshafts on the Maxwell car are drop-forged, heat-treated and ground to one one-thousandth part of an inch and run on multiple bearings, all of which is precisely the same as will be found on other cars.

Crankcase and transmission case are cast from aluminum alloy. This same material is likewise used on these other machines. In our transmission we find one of the greatest variations, but so far as the material and its treatment is concerned they are alike, even to the sand blasting which the gears receive.

The clutch on our cars is different from those employed on any of these, but then every one of the above employs a clutch different from every other. We use the multiple disc type running in oil. We have never used anything else.

The Maxwell radiator is of the cellular type which is found on all three of these cars. It is just as finely constructed, and costs in proportion to its size just as much.

We use an American-made magneto instead of an imported foreign one, as these cars do. We believe that this magneto will give equal results. On the Maxwell car that ran 10,000 miles without stopping its motor we used one of these, and it proved up to our entire satisfaction, giving absolutely no trouble.

The drive from our transmission to the rear axle is the same as is used on all of these cars—that is, a shaft drive with two universal joints. Our rear axle is the standard live type.

The bodies on all Maxwell cars are made of steel instead of aluminum, as is the case on some of these high-priced cars. The difference is that the aluminum costs more and is lighter, but it has not the strength the steel has. The painting of these bodies is much the same in all plants, though our bodies are sand blasted in order to make the paint adhere permanently. All receive approximately the same number of coats of paint.

Maxwell bodies are upholstered in real leather, using real hair for stuffing. This leather is of excellent quality. It does not cost us, however, as much as the specially finished enameled leather used on our more expensive competitors.

All machinery parts in our cars are as accurately made and of as good a quality material as can be furnished. All revolving and reciprocating parts, like the pistons, piston rings, crankshafts, push rods, cylinders, etc., are ground. The material varies

with the different parts, from chrome vanadium to ordinary cast iron, each one of the best for its particular purpose.

Now you will say, if you use the same material and your workmanship is just as good, why the big difference in price?

Well, in the first place, our material is only the same in the vital and important mechanical parts, like the axles, motor, transmission and frame. We save on our bodies. We have by using steel shifting levers, brass plated, instead of solid brass, and so on, and of course with our three enormous plants, with their magnificent equipment, and our tremendous capital, we are enabled to manufacture practically every part in our own shops. This, of course, saves us the profit, parts manufacturers would make were we to buy outside. But the real economy comes in the great quantities which we manufacture and sell.

Our output is three times the output of the Packard, Pierce and Peerless combined. We have only one sales organization for all of these cars, instead of three for one-third the number. Our advertising only costs us what any *one* of these companies would spend. We have only one president and one general manager to pay instead of eight, and then you must remember that when you buy a Tiffany setting you pay for the name "Tiffany." There is no charge for the name "Maxwell" on a Maxwell car.

METZ: C. H. Metz, President—No argument will induce the man who longs for a palace and who has the means to acquire and maintain it, to put up with being in a modest cottage.

The expense of maintaing our little car in comparison with the big tourist is in about the same proportion as the cost of dwelling in a cottage is to the luxury of living in a mansion.

If it is a matter of how many miles per dollar for your automobile use and pleasure, we can figure as close as anyone in the business, and our statements can be substantiated. We do not pretend to tell you what you should purchase, but you owe it to yourself, if your means are limited, to ascertain which car will carry you the farthest with the least trouble and expense, coupled with the greatest amount of comfort. This is what we had in mind when we designed and built our light and serviceable Metz car. That our judgment has been sound is evinced by the recent almost universal tendency abroad for smaller and lighter automobiles.

MIDDLEBY: Middleby Auto Company—Among tbe many reasons why a man should buy our make of car is the fact that we are making a car at a low price, but at the same time giving material and workmanship that goes into a car for twice or three times its price. All the cars of our latest type that we have on the road are giving perfect satisfaction, proving themselves to be cars for all kinds of roads and country.

Another reason that a person should buy a Middleby car is because he can use same all year around without being troubled with the same heating in the Summer time or freezing in the Winter time.

Another reason is because it costs less to maintain than many of the cars made.

MITCHELL: James W. Gilson, Sales Manager—Now that the pendulum has swung around to the popular-priced car, the capacity of the immense Mitchell factory is being taxed to the utmost to supply the demand. Beginning in 1905, just 350 automobiles were marketed. In 1906 the number had been increased to 666, officers of the concern practically planning to increase production twofold each year. The ratio was maintained the following year, the 1907 output being 1,367. In 1908 the production was 2,166 cars despite the hard times, while the 1909 supply was a trifle more than 3,000 cars. The output of 1910 models of all kinds will approximate 6,700 cars, or $7,000,000 worth in round numbers.

Arguing backward from all this demand, which has been built up in a natural and reasonable manner, we think that this slowly but constantly increasing demand for our product on the part of past users and their friends among whom tbey have spread the good word, speaks more highly for the car than could volumes and volumes without end of exaggerated statement.

When the new six-cylinder car to sell at $2,000 was anonunced, the plans called for but 500 of them in 1910. The preliminary announcement brought orders for 1,000, so that the material was ordered on this new basis. Now, it appears as if this would be insufficient to go around. This, like the story of our steady growth, argues strongly in favor of our product, that is, the fact that people want it should mean that it is worthy.

MORA: W. N. Freeman, Treasurer—The reasons why a man who is in the market to purchase a strictly high-grade car of medium size and weight and at a moderate price should place his order for a 1910 Mora is because there is in all the world no power plant like this:

A motor than which there is none better built.

A selective type transmission of same design as has been used in Mora cars for past two years, without replacement of a single gear.

An aluminum pan construction which has been thoroughly tried and tested for four years, supports motor and transmission, keeping both in absolute and permanent alignment, making a unit construction and holding everything in an accessible position to get at as well as serving as a positive mud shield. Completely housed direct shaft drive from selective type transmission to rear axle. Excellent brake construction and spring suspension. Proper arrangement for passenger load with close coupled tonneau, lending luxuriously easy riding and economical wear on tires. Mechanical construction that is right combined with exterior lines graceful and finish strictly high grade.

Very briefly stated the above are a few of the reasons why the 1910 Mora should appeal to the prospective purchasers.

Our company's motto is not how many cars can we build, but how well can we build them.

We court comparison of the Mora with cars selling at twice the price. After careful comparison, we believe, the man who knows will come to the conclusion that the Mora furnishes the greatest value offered for 1910 in high-grade cars.

NATIONAL: National Motor Vehicle Company—The National is available to that class of buyers who want to go fast and far. The motor is designed with large valves, they being fully half the diameter of the cylinder, in diameter. As a result, considering compression, setting of valves, shapes of cams, and the desired accuracy of machining of parts, the motors of this make have torque in proportion to speed, even when the speed is approaching 2,000 revolutions per minute.

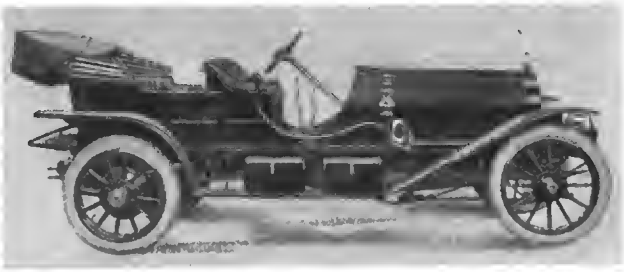
Desiring to deliver automobiles of great power, which is a matter of properly designing the motors, makes it necessary to select the material with great care. As a result, in National crankshafts, for illustration, the material is absolutely without a peer, and the design is that which assures long life, it being the case that the crankshafts are statically, and in a kinetic sense, balanced.

Motors of the National characteristics require profuse lubrictaion, and in the National this matter has been handled without gloves. A competent gear pump, located in the under half of the motor case, delivers the requisite amount of oil to every part to be lubricated, and, in order to tell the driver where he is at, a sight glass is located on the dash, through which the oil must flow on its way. Before National automobiles are delivered to agents or users they are given a thorough test in the shop and on the road, and it is the aim of the maker to have perfect harmony among the cars which make up the product of the National plant. The chief engineer at the National is there for the purpose of fixing quality and he fixes it.

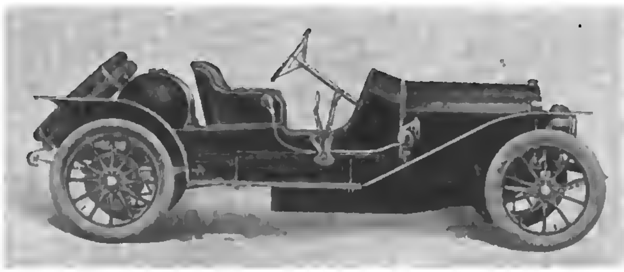
PAIGE-DETROIT: Fred. O. Paige, President—In designing the Paige-Detroit roadster, the aim has been to give the public a perfected vehicle, simple in construction, easily controlled, durable and comfortable for the rider.

McIntyre Four-Cylinder 30-Horsepower Touring

Ohio Four-Cylinder 30-Horsepower Touring



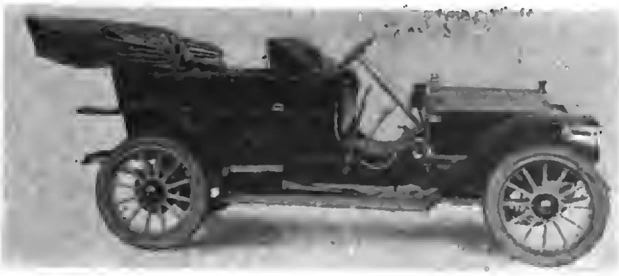
Pennsylvania F Six-Cylinder 54-Horsepower



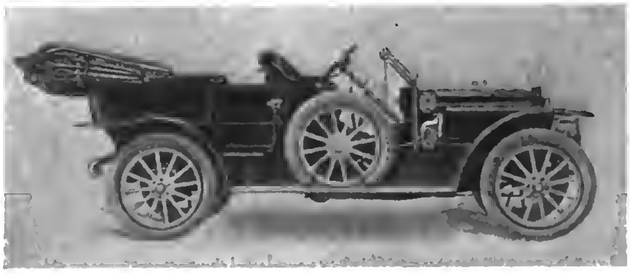
Premier Four-Cylinder 40-Horsepower Runabout

Premier Six-Cylinder 60-Horsepower Touring

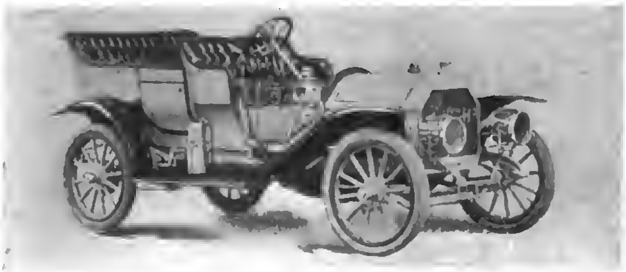
Paterson Four-Cylinder 30-Horsepower Touring



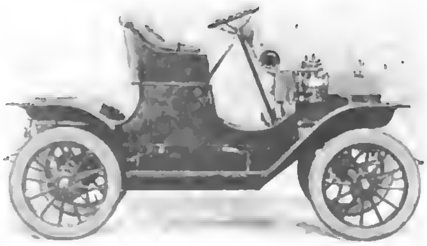
Pullman Four-Cylinder 35-Horsepower



Rambler Four-Cylinder Touring Car



Regal Four-Cylinder 30-Horsepower Touring



Reo One-Cylinder 10-Horsepower Runabout

Our motor is of the valveless, two-cycle, three-cylinder type, thus eliminating over one hundred working parts, found in all four-cycle motors, such as valves, cams, rollers, push rods, rocker arms, springs, etc., with all their bearings and gears, all of which must be kept in good working order. These are the parts which make trouble and require constant attention. The three-cylinder two-cycle engine gives the same results as a six-cylinder, four-cycle.

Spring construction of the Paige-Detroit roadster is a very important feature of the car.

The car in general appearance equals the $3,000 and $4,000 cars.

PARRY: Max. Parry, Advertising Department—Maybe Jack went up the beanstalk, but he would have hustled mighty hard to follow the growth of the Parry Auto Company at Indianapolis. His rival is no other than D. M. Parry, famous as a leader among manufacturers, who incorporated this company last July for $1,000,000, and after gathering about him his corps of designers, mechanics and officials, as well as the superintendent of the greatest auto factory of to-day, he told his dream.

These three facts would allow him to give away more of a car for $1,285 or $1,485 than all others. First, the production must be limited to two models, a roadster and a touring car. Secondly, there should be no experiments to charge to the buyer, and lastly, the 5,000 cars to be produced would permit close figuring on stock, wherewith he ended, "Let's call it the Parry idea."

Then things began to happen. The "idea" grew until in 90 days Mr. Parry was working 350 men, occupying 24 acres of buildings and delivering finished cars to agents. Even as we chronicle these events, the factory is shipping out over 10 machines a day and fast approaching the summit of the year's efforts when every night will close on the production of 35 cars.

A proof of the recognized ability of the Parry Company came in requests for $4,000,000 worth of cars within 30 days after its announcement. The public is demanding a medium-priced car and will certainly take kindly to such as the "Parry," where plenty of power is combined with a pleasing balance of design.

The factory, lately vacated by the Standard Wheel Works, is composed of little over a mile of busy floor space upon which you may watch the complete growth of an automobile. The Parry Company machines many parts, such as crankcases, cylinders, tools and jigs. Motors are assembled at the shops and then set up in a prepared chassis, whereupon the tester breaks it in on the Parry track.

The Parry claims distinction in having a 4 1-4 x 4 1-2-inch motor, which, according to A. L. A. M. rating, owns 30-horsepower. Besides this the valves are in the head, a fact that means less heat and more power. The motor rests on a wheelbase of 116 inches and over this sets a low gray roadster or a big blue touring car. It will be interesting to watch whether this new company can turn out the proposed 5,000 cars. At present the plant is running in a most satisfactory manner and daily gathering momentum for its tremendous schedule. At its head is a capable manufacturer and if you ask him he will smile and tell you it's really too easy.

PIERCE: J. G. Cowling, General Manager—In presenting our Model "K" Pierce-Racine car to the public for 1910, we do so with every confidence, having "tried it out" under all sorts of conditions, in all weathers, and on a great variety of roads.

We have in no way attempted any freaks in our construction, but have confined ourselves to what we consider, from our long experience in motor building, the best of mechanical practice. All working parts have been tested out severely, both in the laboratory and on the road, and the fact that we guarantee the car for one year against breakage due to imperfect parts and workmanship indicates our belief in it.

The motor is the culmination of fifteen years of motor building, and the result is a quiet, smooth running and powerful engine that will take the car anywhere.

No expense has been spared in carrying out the details of construction, such as finish and equipment. Particular attention has been given to spring suspension and balance, and the whole represents a perfect motor car that will satisfy and endure.

PREMIER: H. O. Smith, President—There are numerous reasons why a discriminating buyer would be partial to a Premier, a few of the reasons which we might mention as to "Why buy a Premier," and are valuable to the intending purchaser, especially one who had not previously owned a motor car, as follows:

Because the Premier has fulfilled every promise by performance.

Buying a Premier car is an investment that pays to the buyer big dividends in service and satisfaction.

To prove why one should buy a Premier, the car has been entered into every reliability and endurance contest that promised special difficulties.

Its showing for consistency and reliability in these contests has been second to none.

Because the Premier makers have backed up every assertion they have ever made by performance and not promises.

Because every ounce of material that enters into the construction of the Premier car is the very best that can be obtained from any source or at any price.

The Premier's showing in the reliability contests is a record of consistent performance which is second to no car in the market at any price. These contests, with the observers and the technical examination, provided at the conclusion, not only show up the car and how it stands up in comparison with other cars, but is a test of every part entering into the car, and the proof of the way it stands up in service in the combination.

There is a reason for good showings as well as bad showings. A car after all is only a combination of the several necessary parts, and the whole combination is no better than each and all of the parts.

We believe that the Premier can be judged by any feature of the car which should serve as a criterion, and the proof of the value of these several parts is shown in the results which have been obtained from Premier cars.

This proof, which amply supports the worth of every part of the Premier, should we believe be sufficient grounds for deciding upon the purchase of a Premier car.

PULLMAN: H. R. Averill, Asst. General Manager—The most potent reasons why *your* automobile should be a Pullman are best expressed in the two slogans adopted by its makers—"Not only the best at the price, but the best at any price" and "Some cars cost more to buy, but no car costs more to build."

The fact that Pullman automobiles are made and not assembled by the Pullman Motor Car Company is another very good reason, for every part of these famous automobiles is made under the direct supervision of some officer.

Everything of the best is used in their making, and the broad guarantee under which their agents sell makes unsatisfactory dealings almost impossible.

It is, without question, the ideal family car and to those who seek speed and power they have a model that fills the bill.

It is the winner over 40 times in contests for speed, reliability and hill-climbing, often demonstrating its superiority over other cars of twice the horsepower and cost.

Prospective owners or owners dissatisfied with their present cars will find keen satisfaction in having one of the many agents give them a Pullman demonstration, and it is well worth bearing in mind that when you start anywhere in a Pullman, you get there in the same Pullman.

REGAL: N. I. Taylor, Advertising Department—Some years ago the Regal Motor Car Company built the Regal "30," the first four-cylinder 30-horsepower car to be sold for $1,250; the original car in its class. We have always more than maintained our leadership in this class, leadership in quality, style and perfection of all working parts. The Regal "30" of to-day is not a new car, but an evolutionary product, a good car with years of experience back of it, which has been continually improved and refined, until to-day it stands unquestionably recognized as the greatest automobile value in America for $1,250.

You should buy a Regal "30," because we positively know that in buying a Regal car you get better value for $1,250 than you can duplicate in any other car listed at less than $2,000. Its perfect construction, superior quality of material used, beauty of design and easy riding qualities most readily recommend it to the most exacting buyer. The Regal "30" is a beautiful traveler on rough roads and an exceptional hill climber.

Anything you want in any car at any price you'll find it in the Regal. Regal "30" can accomplish anything any other car will. The cost of maintenance and upkeep is at a minimum. We have not been annually expending enormous sums in experimenting on new cars, but our every effort has been directed toward the perfection of the Regal "30." This car is a finished product in every detail and readily meets the demands of the most critical purchasers. Regal "30" is a quality car, without the unnecessary frills. You cannot buy a better car at twice the expenditure.

REO: R. M. Owen—As a reason why one should purchase a Reo in preference to some other companies, the manufacturers offer the left-hand drive, with its attendant safety, comfort and efficiency. It is not possible to go into all of the positive advantages which left-hand control affords over the old. Suffice to say the step is well justified in the rapidly increasing popularity among experienced drivers and owners.

The reasons for the popularity of the left-hand drive at once become obvious when the questions of comfort, safety, economy, convenience and efficiency are carefully considered. Take the instance where the statutes or local ordinances require all vehicles to be so placed and headed in public thoroughfares that the right side of the car is next to the curbing. It will readily be seen that with the levers on the left side the occupants of the front seat may step directly upon the sidewalk. This is of positive advantage to both the driver and owner.

A word as to safety, comfort and efficiency. With the left drive the operator's left hand is free to shift the levers and blow the horn. This permits the exclusive use of the right hand for the steering wheel. The opposite of this prevails under the old method. There the driver must almost invariably make a quick change in handling the steering wheel from his right hand to the left in order to be able to shift the levers. Result: Two movements to do what is now done by one with the left drive. After once experiencing the happy contrast in favor of the left-hand drive very few drivers, if, indeed, any at all, would drop the new for the old.

Further, on narrow roads the driver with the left-hand drive is able to gauge more safely the clearance when passing other vehicles. This is especially true where the roads are narrow, sharply crowned and poorly ditched. Another case of comfort plus safety equalling preference and popularity for the left-hand drive. Then it is claimed by eminent automobile engineers that the running of the vertical motor placed in front tends to depress the right side of the car which is largely overcome by placing the driver on the left side.

Doctors, rear estate men, contractors, farmers, clergymen and other business and professional men, who largely do their own driving, are especially enthusiastic over the Reo left-hand drive. The foregoing convenience, means of added comfort, economy, safety and efficiency, besides the many other practical advantages too numerous to mention herein partially account for its popularity. It may therefore safely be said that the left-hand drive will, in another year, become practically universal.

SCHACHT: Walter H. Sly, Treasurer—The Schacht car should be purchased in preference to any machine offered at a medium price, because it is a car so designed that it can be used for any purpose that might be required of an automobile. The Schacht is fitted virtually with a combination body which can be changed in five minutes from a runabout into a surrey or family car, or a light delivery wagon, by merely rearranging the rear seat. This machine has an extra long wheelbase, which allows plenty of room back of the seat to carry goods of any description, up to a capacity of 800 pounds, and it is a machine which will readily appeal to the merchant, farmer, salesman, or any class which requires a car that must answer every purpose of a general utility machine.

There is also a patented mechanical feature on the Schacht entirely individual to it, and this consists of a double-acting clutch built into the flywheel of the motor. While a planetary transmission is used in this car, every previous objection to this type of transmission is eliminated by the fact that the transmission does not revolve on the jackshaft until the clutch is engaged in the flywheel of the motor and the car moves forward, thereby clamping the bands on the transmission and avoiding all the customary rattle, which is caused on the planetary type when the car is stationary with the motor running.

In other words the transmission is never revolved until the clutch is thrown in when the car will be in motion, and in order for the car to be in motion the bands clamp the transmission, otherwise transmission cannot revolve unless car is moving.

SPEEDWELL: H. A. Wright, Advertising Manager—Any man who drives or wishes to drive a large car should buy a Speedwell because it is superb in line and finish, because it has ample power and speed and is easy riding and extremely flexible and obedient in control.

These things granted (a demonstration instantly shows them to be true), then the only thing left to be desired to make this the ideal car is the assurance that it is properly constructed to give long life and minimum of repairs. Because in the Speedwell are found only the highest grades of materials possible to buy, and because the workmanship in the car is the best and most careful; because the car is subjected to most thorough tests and inspection in every particular—because of all these things this car does "stand up" and give most satisfactory service for years.

Now comes the real reason for buying a Speedwell. There are a few other cars approximately on a plane with the Speedwell, but none is sold at the Speedwell price—$2,500. To get equal value in any other car you must pay one to two thousand dollars more. We concentrate all our efforts to one standard chassis with different style of bodies.

FOREIGN PLEASURE CARS

DE DION-BOUTON: George Ozanne, Manager American Branch—It is our idea that the superiority of the De Dion-Bouton motor car lies in the following facts:

1. Being the oldest manufacturing concern of small and medium cars, it has the lead of experience.
2. Its motor is the prototype of all modern gasoline motors, and it is the only one which has been endorsed by other automobile manufacturers, who have, in such large numbers, adopted the De Dion-Bouton motor for their cars. This constitutes a unique acknowledgment of the superiority of the De Dion motor.
3. Our transmission by cardan shafts is the only one which has all the advantages of the chain, and none of its inconveniences.
4. The automatic lubrication system, under pressure, of the De Dion-Bouton cars has never been equalled, and this has been one of the good reasons why the reputation of "The most durable" has always been synonymous to "De Dion-Bouton."

PANHARD: A. de Magnin, Assistant Manager American Branch—The Panhard car has always had the reputation of being the most durable and reliable one manufactured; the construction of the chassis is of the completest finish.

In purchasing a car of recent years the buyer knows that he can compare the weight with that of the lightest car made, and at the same time combining strength and comfort. He will get a motor silent, supple, and whose climbing ability is remarkable, as well as having the best in the market as to material, workmanship and design. In addressing himself to the Panhard & Levassor Company the prospective buyer deals with a firm which is the pioneer of the automobile business, and one that has acquired its experience by severest tests.

When buying a car the customer knows that he gets not only the best of automobiles and the most simple and complete chassis, but is also backed by a reliable firm. He knows also that he is buying a car which will last him for years, for, as can be seen in the streets of any city in the world, Panhard cars made ten and twelve years ago are still giving constant service and satisfaction.

Besides, we have reduced the prices of our chassis so as to meet American competition, making very little difference between the cost of a high-class American car and the Panhard, which has always been known as the highest priced automobile manufactured.

RENAULT: Paul Lacroix, Manager American Branch—Chief among the reasons why one should buy a Renault car, that is, an American, for on the other side reasons are not necessary, is the fact that this leader among French constructors has always sought for and catered to the high-class American trade. This tendency is distinctly shown in the list of 1910 cars, this including one special model designed specifically for American roads. It is a four-cylinder touring car with 25-35 horsepower engine. In this engine the long stroke has been particularly emphasized, the motor having a bore of 4 1-2 in., while the stroke is 6 1-2 in. This gives a ratio of 1 to 1.45, and as a result, the power developed by this motor is greater than other motors of similar bore, but lessened stroke. The construction of this special model for American roads is of itself an argument why one should buy this make of car. Other reasons are the unusually complete Renault line, extending from 8 horsepower up to 50-60.

AMERICAN COMMERCIAL CARS

CHASE: A. M. Chase, President—The Chase motor wagons are built for delivery service in all classes of business. The goal of our designers is to eliminate all unnecessary parts and to produce a machine which will operate continuously with the minimum of care and expense.

Chase valveless two-cycle air-cooled motor most nearly approaches the ideal commercial car motor. The only moving parts are the pistons, connectings rods and crankshaft.

Chase motors use a system of mixing the lubricated oil in the gasoline tank and allowing it to feed to the motor in proportion as the engine uses gasoline. This not only insures perfect lubrication of the motor, but eliminates every particle from the mechanism in the lubricated system. The advantages of air cooling are well known. Delivery wagons must operate under all weather conditions, and it is a great advantage not to have any water system to leak and freeze.

Planetary transmission as used on the Chase cars is enclosed in an oil-tight malleable iron case which prevents any dust or dirt getting inside of the gearing and causing wear.

High wheel construction is very economical, as it reduces the tire expense to practically one-third of that of pneumatic tired vehicles doing the same amount of work. The large diameter wheels go over obstructions with less jar than small diameter wheels. The high wheels go over bad roads without injury to the tires and with low power consumption from the motor.

Motor is located in front under the hood, and is easy to get at.

Every progressive business man likes to have his delivery cars have a good appearance and a high-grade finish. The Chase motor answers this demand in every way. In this age many persons purchase their parts and assemble their cars in their own factory. The Chase motor wagons are built entirely in the Chase factory, and visitors to the plant are impressed with the thoroughness which is exhibited in all departments in the manufactory of the various parts which go to make up this successful delivery car.

GRABOWSKY: Grabowsky Power Wagon Company—The power plant in the Grabowsky, for good and sufficient reasons, may be removed and replaced within the fourth part of an hour. The work may be performed by a man of no great skill; the result is, in service, ten wagons, with eleven motors, make it possible to keep the ten wagons on the go constantly, and it is when they are on the go that they pay interest on the investment.

The Grabowsky idea is to build good wagons, and, what is equally important, to so design them that they may be maintained for years. This is brought about by having every bearing so made that it can readily be replaced by the man at the garage, and every time a bearing is replaced that part of the wagon is made as good as new. The replacement may be made at small cost, and the time required is but slight. In all other respects the Grabowsky method takes into account not first cost, but cost of maintenance, which is a matter of knowing how, then doing it that way.

GRAMM-LOGAN: B. A. Gramm, General Manager—We wish to state that in our exhibit in the coming Grand Central Palace Show we believe that the public can very easily see why we claim the world's best in the Gramm-Logan truck chassis. The reason why we make this claim is ten years of painstaking labor day and night by engineers grown up in the business, perfecting these chassis from a point of daily use in all parts of the country; the use of the very finest materials that have been studied to give the best satisfaction in the different parts of the chassis; a factory equipped with machinery built especially for our purpose, and with tools designed only for this work, and with plenty of capital back of us to properly carry out our work.

Our truck has features not to be found on any other, and every one of our customers in the past year reports the very finest of satisfaction. Our output in our present plant was sold up early, and we are rushing our new plant in order to take care of our business. The last reason why we claim the Gramm-Logan to be the best is because it is to-day the most widely copied chassis in point of design and construction on the American market, and is undoubtedly a year in advance of any other make.

RANDOLPH: H. E. Haase, Advertising Manager—The Randolph Motor Car Company has, with careful consideration of modern practice, as well as all innovations and radical tendencies, placed a line of cars upon the market which are evidently a strong combination of reliability, simplicity, strength and attractive appearance.

In accordance with the requirements of "Solid Tire Practice," the car is heavily proportioned throughout, and is designed to withstand all strain and racking effort of commercial usage. Ample power, positive lubrication and the governing of the engine speed are important features which have been given due consideration.

This concern has established agencies in all the important cities in this country, and have cars in the service of the best known concerns in the country.

NOTE—Many absentees will be noticed in the foregoing, Reasons Why One Should Buy, but the Editorial Department of THE AUTOMOBILE takes this opportunity of stating that all had equal opportunities, and those who absented themselves did so from choice or neglect.

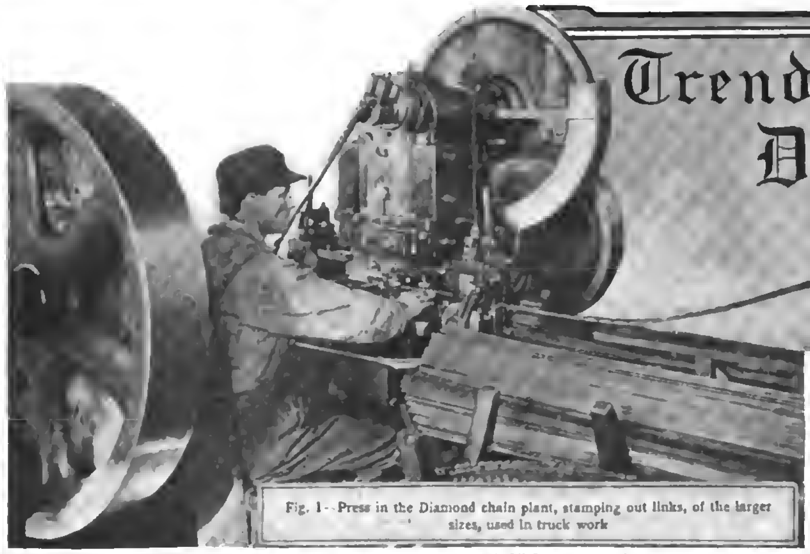

Fig. 1 – Press in the Diamond chain plant, stamping out links, of the larger sizes, used in truck work

Trend in Design and Fashion

By
Thos. J. Fay

FIRST PRINCIPLES are observed in the better plants of the day, and departure from them, if such there is, traces but the incident of the moment, and in plants undergoing organization, rather than in those of the A. M. C. M. A., which for the most part have stood the "acid test" as it were, having developed along pioneer lines, made haste but slowly, scanned the horizon for the sight of breakers ahead, which were rendered impotent by the simple process of steering clear of them.

In the display of automobiles, accessories and parts which is about to be inaugurated, and which will be viewed by a waiting concourse, beginning December 31, at the Grand Central Palace, there will be seven long days at the disposal of interested spectators in which to gorge themselves with imprints of the good points abounding in the products. In this display, however, little will be found which will tell of the processes, and, since a stream must have its headwater, so must this display emanate from a competent source, which is brains, brawn, system and facilities.

Of the brains and brawn little need be said; in America these qualities are indigene. System is but the expression of consolidated experience, there being now a plenty, while for facilities let us make them the gist of this subject and revel in them for a pace, measuring their depth and width and breadth.

Hindrances and Facilities Separated—Makers of automobiles, remembering the hindrances of the older industries, carefully avoided them in the newer work, and in so doing located plants at points of vantage, adjacent to trunk lines, waterways, and in juxtaposition to materials of the desired stamp.

Hindrances, as they relate to labor, come when the class of work to be done is different from the habitual undertakings of a community of laborers, and this phase of the problem has been adequately cared for, which gives to makers of automobiles a class of artisans in sufficient force to render conspicuous services.

Sanitation, light, heat, and pleasant surroundings, while they may be as strangers in certain industrial establishments, have been most carefully utilized in the newer plants, notably those designed for purposes of turning out automobiles, and, strange as it may seem to some, the quality of product increases with the output under such conditions.

Special Machine Tools Developed to Order—In kinetic machines, such as automobiles, alloy steel is necessary in many of the more important parts, and even the components which are fashioned from the more ordinary grades of steel are made from materials of better selections than would be true in many other genera of machines. This advance in the rigidity and dynamic ability of the materials used soon rendered manifest to builders that machine tools as they were formerly made were not rigid enough for the purpose, and rather than slide back into the beaten path of indifferent success, pressure was applied to makers of machine tools, who happily, with ear to ground, measured the impetus of the wave and responded.

It is the advance which has been made in machine tools and methods that holds the real story of the year, and when the patrons of the industry view the product of a twelvemonth at the Palace, the most interesting part of the things to consider will be in the mind's eye of the onlooker who makes himself familiar with the processes involved.

It is this very advance in process which serves as the substantial foundation on which the greatly increased output of this year stands, quantity, in fact, beyond the dreams of the men of a thrice of years ago, yet, with all, quality is on a higher plane than formerly, showing that precise method—in short, system—holds sway, among which the following are conspicuous:

CYLINDERS ARE JIGGED, MILLED AND GROUND

Accuracy, as it is represented by narrow limits of tolerance, is the modern requirement in cylinder-making, and this is accomplished with great certainty by utilizing mahogany patterns of good workmanship after drawings of competence, in which limits of tolerance are properly set forth, and in the foundry such care is given in charging the cupola and otherwise that the castings will be sound, free from surface blemishes, close-grained and of adequate strength. The most recent undertaking in this connection is by way of the introduction of a percentage of steel scrap in the charge, as in Premier practice, with special means of rendering the teeming mass amenable to the process. The castings thus evolved are especially close in texture, are fully 50 per cent stronger than normal cast gray iron, and come out of the moulds in such good fettle that few indeed are the "wasters" to be counted.

MULTIPLE HEAD MILLING PLANER WORK

In many of the most modern shops, in view of desired speed and great accuracy, cylinders are placed on the planer bed, as many as 16 in a row, and having been designed with a view to the multiple milling of all faces (and further provided milling attachments to the planer), the work is conducted on a large scale, much as is depicted in Fig. 2. In this example, in view of other operations and conditions, the valve-cover bosses are left for a separate operation; otherwise all faces are done at one time, and owing to the accuracy of the equipment the process is quick.

JIG METHODS OBTAIN TO A VAST EXTENT

Having provided a suitable multiple drill, which in these days is the easiest equipment to procure, it is at once possible to provide jigs which will take the cylinders, hold them in the correct relation and enable the operator to advance the work with great speed, doing as many as 24 operations at one setting in some in-

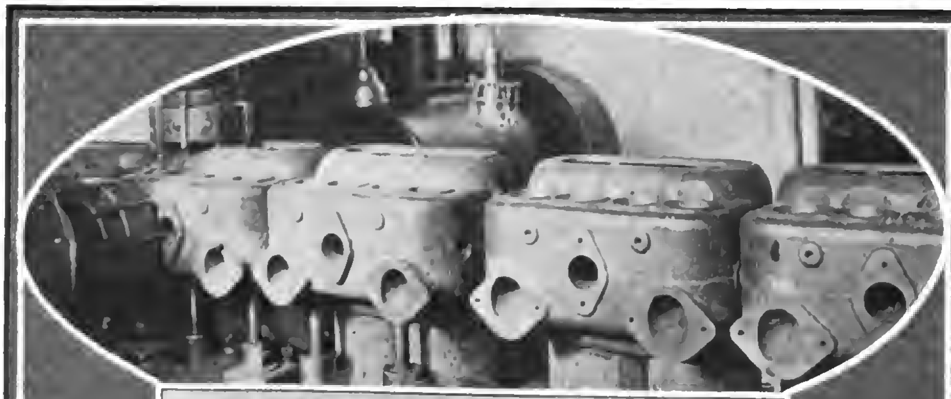

Fig. 2—Facing cylinders on a gang-planer fitted up with multiple milling heads and special fixtures in the Inter-State

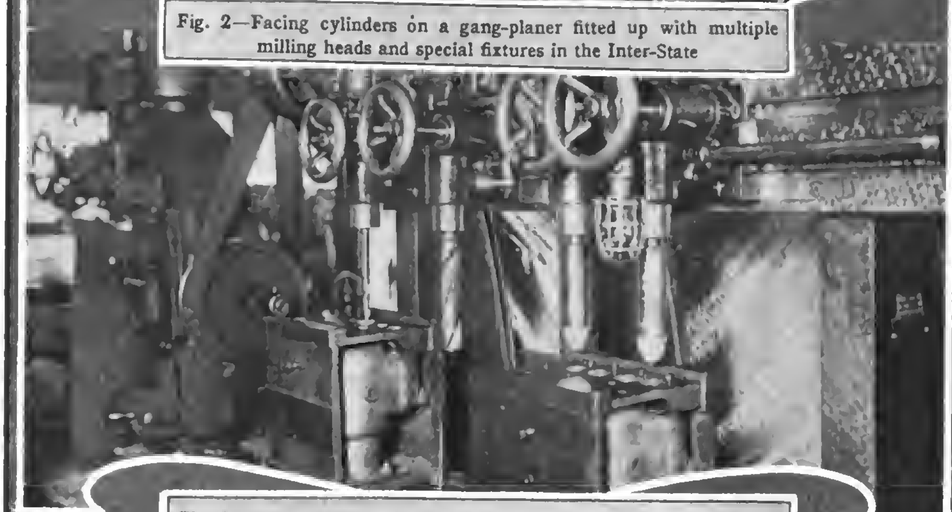

Fig. 3—Special multiple-spindle drill in conjunction with jigs, working on Inter-State cylinders

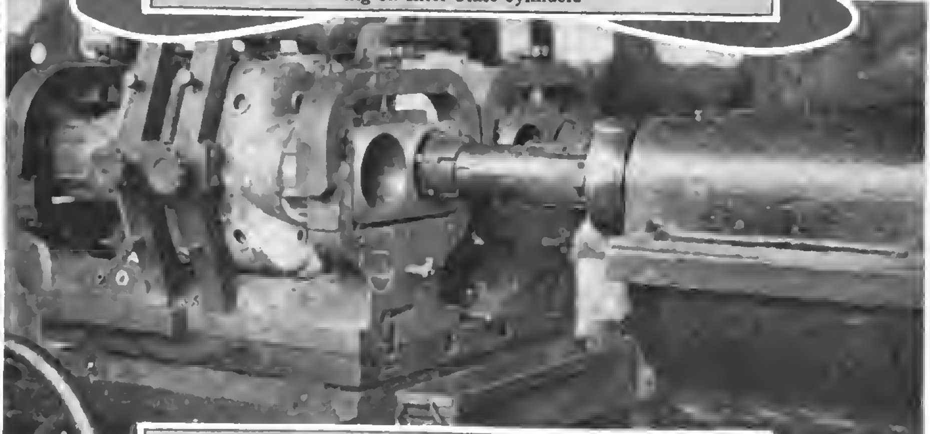

Fig. 4—In the National, boring cylinders on a special tool, holding four sets of twin-cylinders on a turntable

Fig. 5—Heald cylinder grinding machine, as used in connection with National cars, with water jacketing to defeat expansion

stances. Fig. 3 is of a good example of this character of work, and the illustration seems sufficiently comprehensive to show.

BORING DONE AT HIGH SPEED

Referring to Fig. 4, of a twin boring bar used for wroughing out the bores of cylinders, it will be seen that enough cylinders for two motors are placed in the fixtures at one time, and the cutters on the two spindles (having inserted teeth) are of high-speed steel and capable of being pushed to the limit. When two bores are completed the table is feed across and the second set of cylinders are then bored. When these cylinders are finished the table, turning on its axis, is swung around and the cycle of operations is repeated as before. While this work is going on the workman places other cylinders in the fixtures which are idle, and in this way the performance becomes continuous. When the work is pushed very hard, and in the absence of any method of holding a constant temperature, the bores will be distorted quite a little, and in some plants it is the custom to "age" the cylinders and then subject them to a second boring operation.

GRINDING IS ALMOST UNIVERSAL

The Heald grinder, as shown in Fig. 5, is seen in almost every automobile plant in America, and, as the illustration clearly indicates, a fixture is available for holding the cylinders while they are being ground, it being a simple angle-plate, to which they are bolted after the flanging face is finished. Since there is but one spindle, and two bores to be ground, a means is provided for feeding across, in order that the second bore may be ground. While grinding cylinders water is circulated through the jacket and in this way the bore is finished to great accuracy, since expansion due to heat is aborted.

Modern Trend in Cylinder Designing—Cylinder designing may be placed in the classes as follows:

(A) Valves in the head-air and water cooling being in vogue.

(B) T-shapes, noted for symmetry —water cooled.

(C) L-shapes, eliminating the need of one camshaft water cooled.

Valves in the head are much more in vogue than formerly, there being no question of the ability of this type to deliver the maximum power, which accounts for the type being used in racing to a considerable extent.

T-shapes are holding their own; they assure absence of unequal expansion, but demand a somewhat larger radiator in the cooling process, due to a considerable increase in the flame-swept surface.

L-shapes, because they eliminate a camshaft, are favorites, and as respects unequal expansion, they do not give trouble. The flame-swept surface is somewhat more than in the types with valves in the head.

PISTON AND RING DEMANDS

Owing to the demand for higher weight efficiency in motors, and in view of the influence of weight of the reciprocating parts on the secondary moments limiting power by limiting safe speed, it is the most pronounced idea at the present time to employ very superior grades of piston iron, which to be sure are the product of gray iron foundries, but the castings are white in their tendency, taking on, strange to relate, such characteristics as abound in stove castings—the average person laboring under the mistaken notion that stove castings are inferior. As to rings, what is true of pistons also holds good, and to a considerable extent, although for them to be fragile is to reduce the value of them to near zero. As for connecting rods, since they belong to the reciprocating mass, they must be coped with simultaneously, and in the best practice of the day they are made of rather rigid drop-forged steel, in I-sections for the most part.

MACHINED ON SPECIAL TOOLS

Nothing can serve better to illustrate the methods in vogue than the illustration here afforded as Fig. 6, it being a turret lathe, provided with a special tool-post and cutters to suit. The piston is first bored out, and with this bore to go by the piston is fitted over a mandrel, which is screwed onto the lathe spindle, and the grooves, as well as the exterior finish, are done as a single operation. From this tool the pistons are sent to the grinding department, where they are sized and closely finished.

PISTON RINGS DEMAND GREATEST CARE

Piston ring stock comes from the foundry in the form of a cast-iron tube of the required length and thickness of wall to turn out the rings of the right size, and enough of them to complete a motor, there being, as a rule, four rings to the piston, making 16 rings for a four-cylinder motor. After the tube is turned to near size, in as well as outside, it is slipped over a mandrel, as shown in Fig. 7, and the operation of parting is conducted, leaving each ring with grinding "finish."

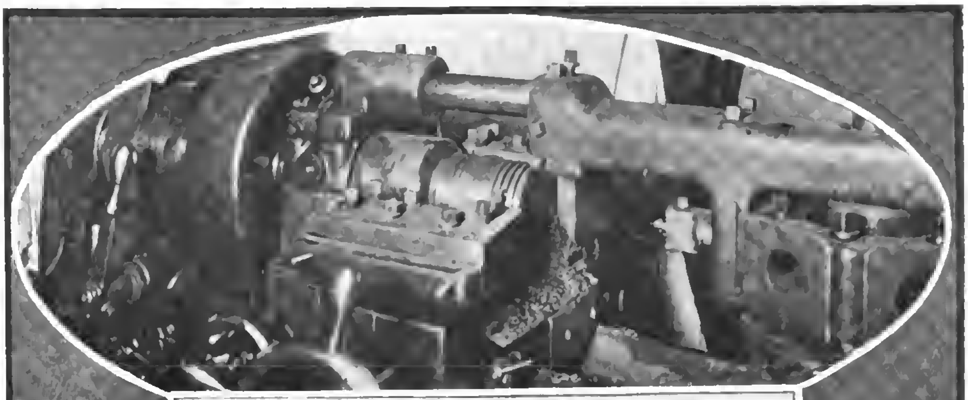

Fig. 6 Special turret lathe, in the Inter-State, working on pistons, turning, grooving, and facing simultaneously

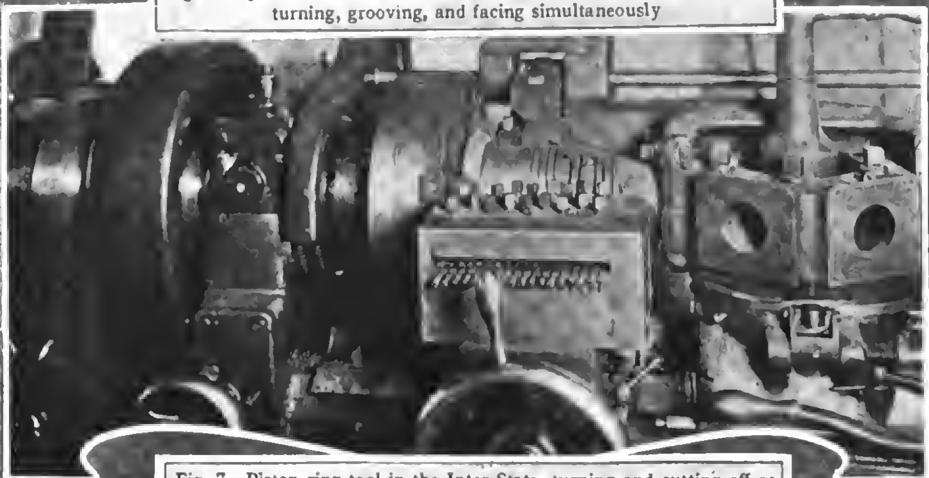

Fig. 7 Piston ring tool in the Inter-State, turning and cutting off as a continuous performance

Fig. 8 Magnetic chucking flat grinder working on piston rings as used in Inter-State cars

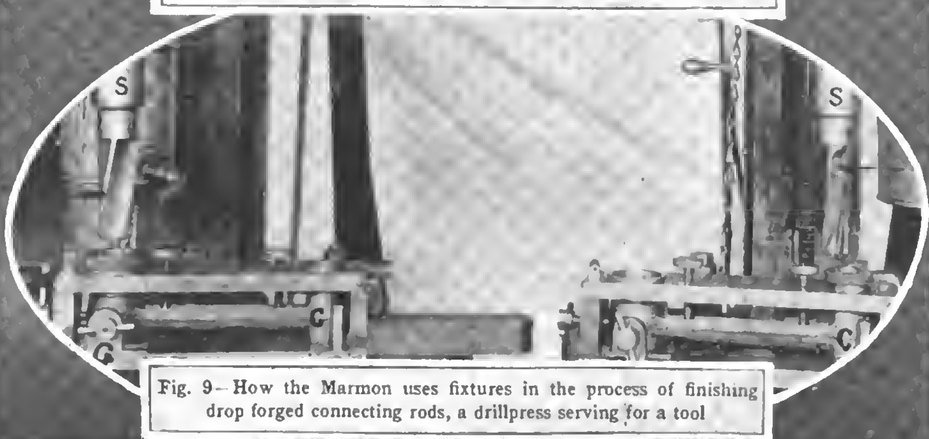

Fig. 9—How the Marmon uses fixtures in the process of finishing drop forged connecting rods, a drillpress serving for a tool

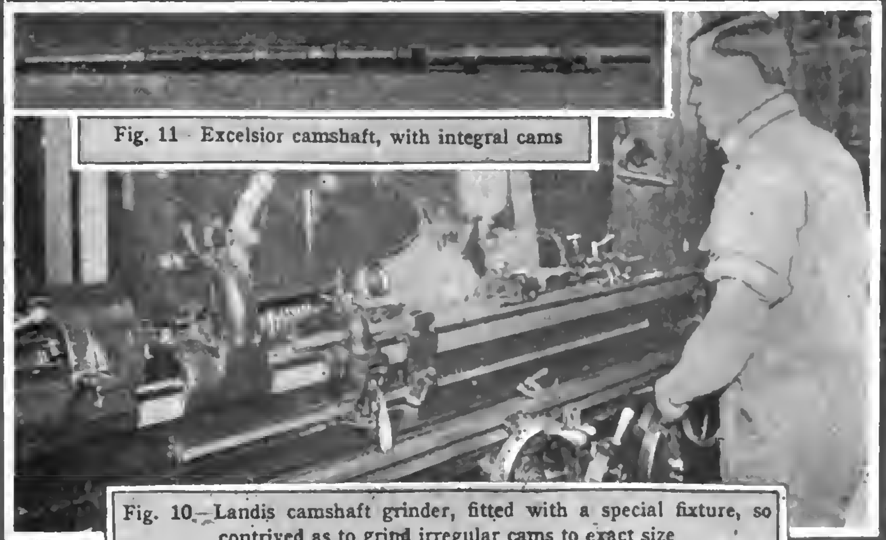

Fig. 11—Excelsior camshaft, with integral cams

Fig. 10—Landis camshaft grinder, fitted with a special fixture, so contrived as to grind irregular cams to exact size

CONNECTING RODS ARE MILLED

Referring to Fig. 9, it will be noted that a straddle mill is set to face off the enlargements, they being clamped in place for the purpose. There are several forms of fixtures in vogue, and in some of them provision is made to turn the connecting rods end for end, thus allowing the work of facing off the enlargements at both ends to be done at a single clamping. In some shops the fixtures contrived for this purpose are very ingenious, being so made that the pistons are locked in and come in the right relation automatically, with relatively small expenditure of time.

ANNEALING IS NECESSARY

Connecting rods, being drop-forged, are not of necessity in good fettle when they come from the forge, and in the better grade of motors they are subjected to a correcting process before they are machined. This is but a matter of annealing at the right temperature for a certain length of time; true, it is desirable to check the grades of material, it being the case that if the carbon is too high the results will not be so good. Sand blasting is resorted to rather than pickeling this year, and the experience is that this process is superior; it takes less time, removes the skin, and discloses the metal to the eye of the inspector, who, after a little skill, is enabled to determine conditions.

RING GRINDING ACCURATE

After the rings are parted they go to the surface grinder, fitted with a magnetic chuck as depicted in Fig. 8, where they are placed on the flat (magnetic) chuck and the grinding disc passes over the surfaces as many times as may be demanded to bring a true, polished surface. When one side is finished the rings are turned over and the same operation is repeated; in this way the rings are brought to within a small fraction of a "thousandth" of dead accuracy, involving a free fit, and with the grooves properly sized in the pistons there is no question of the results; the pistons will hold compression. It is the practice this year to more carefully fit rings than it ever was before, and the power now realized is in a large measure accomplished.

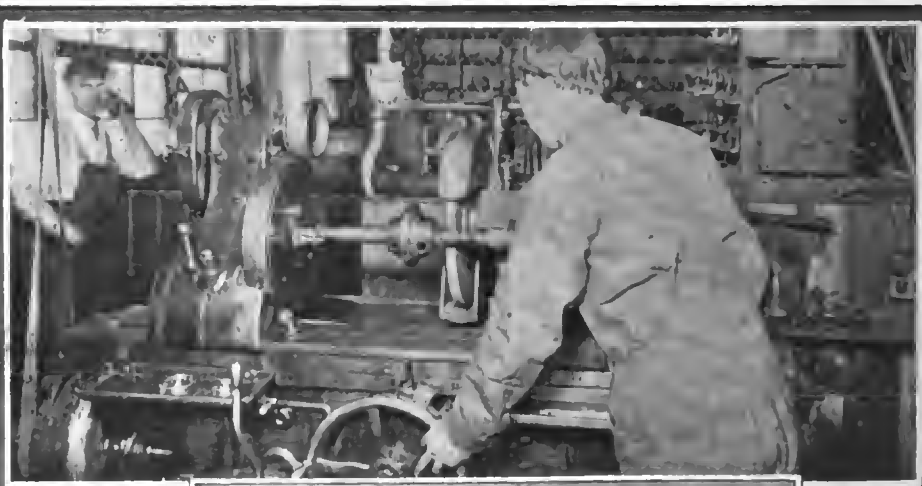

Fig. 12—Grinder used in the Woods plant for work of an exacting character, as fitting ball bearings, etc.

Fig. 13—Grinder used in the Rambler plant for finishing crankshafts to exact size, they having four throws in this case

CAMSHAFTS MAKE ADVANCE

Irregularity in the contour of cams and difficulty involved in accurately shaping them has led to many innovations in the process, and even to this day, for divers reasons, some of the representative builders of motors prefer to use separable cams, which they fasten on in one way or another. Fig. 10 presents the newest and perhaps the most advanced possible way of doing this class of work, in which a special grinding fixture is attached to a regular type of grinding tool. The finished camshaft is as shown in Fig. 11, which was made for a motor with four cylinders, of the L-headed variety, thus requiring eight cams to the shaft. The cams are cut integral—that is to say, with a drop forging to start with in which the cams appear all near size, and after roughing between the cams, which is done in centers on a lathe, the camshafts are hardened and then set up in the grinding attachment on the grinder as shown. In this work the attachment is located eccentric to the fixed centers of the grinder, and by means of master cams, which are just like the cams to be finished (but on a larger scale), the camshaft shifts on its eccentric centers exactly to conform to the surfaces to be ground, thus making it possible to grind the cams, no matter how they may be shaped for the final finish, or how hard they may be. It is of the greatest advantage to thus be able to do the grinding after the camshaft is hardened, for in this way the effect of deformation is not so much of a trouble to cope with. The cams thus made are less expensive, may be of harder material, and the time required in machining and finishing is much reduced. Accuracy in timing is assured since the cams are ground to conform to the master, which master cam can be made to exact size by a toolmaker of skill.

Fig. 14—Flat grinder used in the Inter-State for finishing manifold fittings, also fitted with a magnetic chuck for some jobs

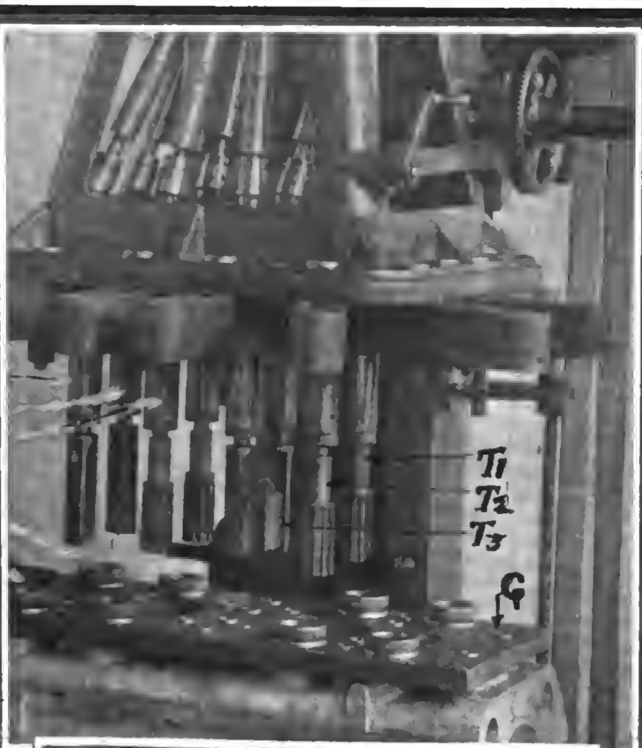

Fig. 15—Multiple-spindle drill as used in the Marmon plant in conjunction with a jig for crankcase work

GRINDING IN GENERAL ON THE INCREASE

In almost every shop, as never before, grinding is resorted to to a vast extent, and Fig. 12 is indicative of the advantages to be derived, in which a differential housing is being trued up by the grinding process after it is finished. This truing up process, as well as assuring concentricity, has the advantage of affording a "sucking fit" for the annular ball bearings used in this product. It must be well understood that ball bearings, however good they may be, will not afford complete satisfaction unless they are nicely mounted, and in the products of the year, in view of advances made in machine tools (especially in grinding processes), this phase of the work is being done to a nicety.

Crankshafts Almost Invariably Ground—These important members in motors are machined to within about ten-thousandths of the final size, both at the main bearings and the pins. They are then set up in centers on grinding machines, as illustrated in Fig. 13, where they are reduced to exact diameter, less a fraction of a thousandth of an inch above size. The result is that the sizes are not only neat, but elliptical formations are aborted. It will readily be appreciated that an elliptic journal is scarcely likely to improve the journal-box in which it must run.

Surface Grinding Now a Settled Method—There are many operations of an important nature, connected with motors in particular, which can best be performed on a surface grinder of a type as depicted in Fig. 14, and in some instances a magnetic chuck is added, in order to save time in the setting up of the work. The particular job being done does not demand the use of the magnetic chuck, and it is eliminated in this case. The grinder is facing off the fittings of a manifold for a motor, and when such nice work is done it is then that "packing" may be omitted, and few indeed will fail to rejoice at the omission.

Internal Grinding Just as Handy—Besides the several classes of grinding to which specific reference were made, there are the several kinds of internal grinding done, and the little grinders which do this work are largely responsible for the lack of noise that makes cars of this time so conspicuous when they run as companions down the roadway alongside of some of the older but more noisy models of a year or two ago.

USES OF MULTIPLE SPINDLE DRILLS

Expensive special machine tools in many of the shops account for the quality of the work done, but it is not absolutely neces-

Fig. 16—At the National, showing a special application of a radial drill, with a special fixture, boring three rows of bearing holes at one time

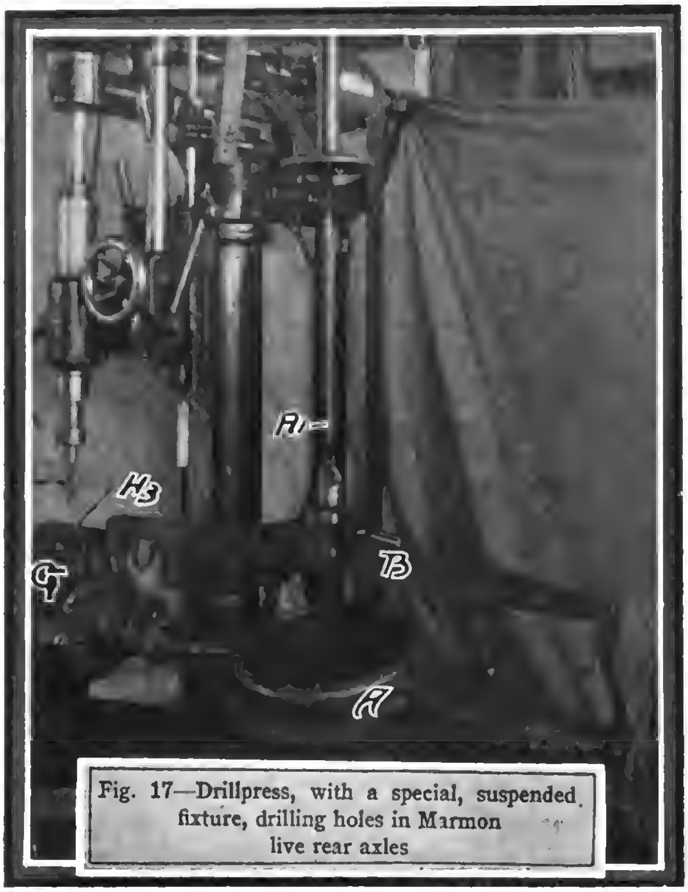

Fig. 17—Drillpress, with a special, suspended fixture, drilling holes in Marmon live rear axles

sary to use them, nor will the quality of the work done fall below a desirable standard in the absence of them—in fact, in the shop it is true that "fine feathers do not necessarily make fine birds," so to speak, referring to machining processes.

Multiple-spindle drills, in conjunction with accurately made jigs, are of the greatest utility, the quality of the work done being as accurate as drilling and reaming can make it, and that the holes, bores and finishes will come right is assured by the accuracy of the jigs used to guide the cutting tools. Fig. 15 is of a multiple-spindle drill of the latest and most useful type, in which the reamers T1, T2, T3, etc., are guided by the jig G1 into the proper places in the crankcase C1 and the work is quickly and accurately done. Universal joints, J1, J2, J3, etc., are responsible for the manner of transmitting the power to the respective tools; compactness is prominent, and toolroom accuracy is self-evident.

Radial drills come in very handy in many undertakings, and under the guidance of men who understand the jig and fixture requirement the result is on a high plane. Fig. 16 is indicative of the highest attainable result, in which a radial drill is used in connection with a fixture which carries three boring bars, they being so geared and related as to serve to bore the bearing holes all at one time with great accuracy, in a crankcase, at small loss in time.

Perhaps Fig. 17 is the most ingenious of all; it is of a drill press of the conventional sort, in which the work is a live rear axle A, suspended by the balancing arm B, and the jig G guides the drill D through the bushed hole H, the balancing arm B being suspended by the rod R. It will be noted that the axle is held in the jig by the spindle, which fits in the round of the jig.

What the automobile has done for machine tools is more than will be fully appreciated, and at the present time, in view of the demand for men of great skill, the industry has absorbed every available toolmaker, especially of the class capable of coping with the very problems as referred to in connection with the fullest use of standard machine tools as the drill presses as here presented.

APPRENTICE SYSTEM BEING REVIVED AND EXTENDED

Owing to a growing scarcity of competent labor and with a view to training up a special class of men, they to be skilled in automobile work, the various systems of apprenticeship are being investigated and some of them are being tried out at length. One of the best possibilities lies in the co-operation of the companies with trade schools, in which it is the aim to take the boys on part time and pay them for the work they do, thus helping them to go through school and at the same time learn a trade. That these boys will fill a useful part in the building of automobiles in the near future is fully believed by all who take an interest in this phase of the problem.

PRESSED STEEL PLAYS AN IMPORTANT PART

Looking backward for several years discloses no such advance over any other year made during the past twelve months when reference is had to pressed steel work, as sidebars, crossbars and other parts as used in chassis frames, and in other important parts, namely, brakedrums, brackets, shields, etc.

In the production of sidebars, especially those of the kickup design, and when they are spread as well, the presses are required to be very large and substantial, one of which is here portrayed as Fig. 18, in operation, pressing a sidebar of the character as employed in the manufacture of chassis frames.

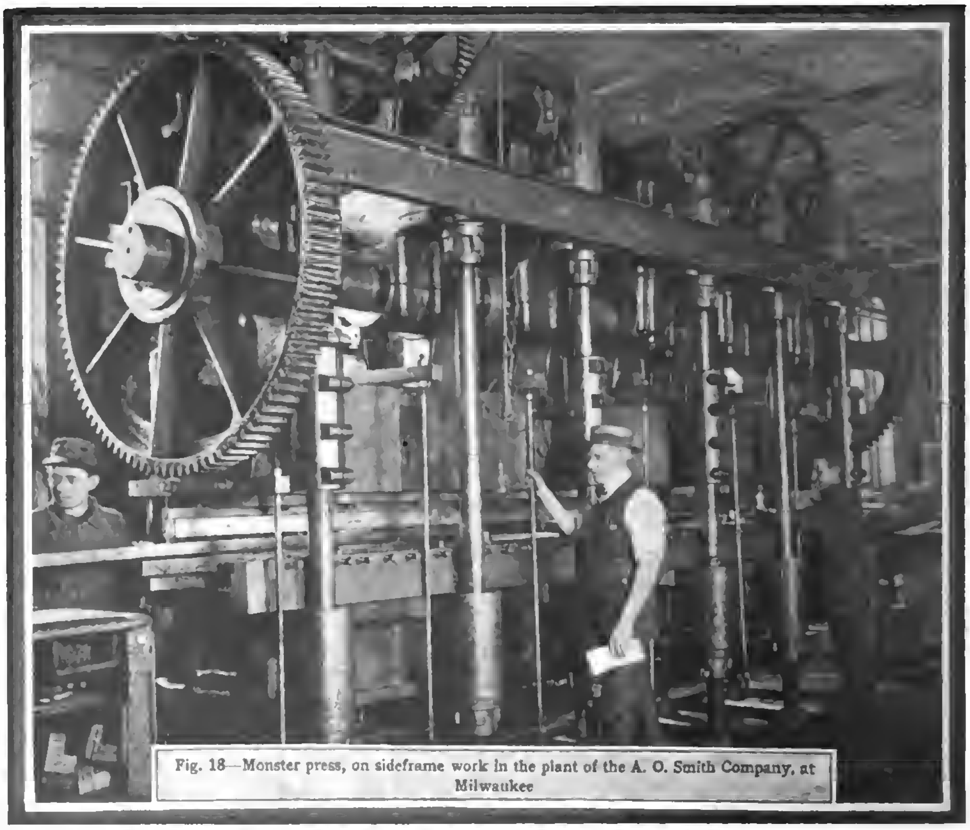

Fig. 18—Monster press, on sideframe work in the plant of the A. O. Smith Company, at Milwaukee

Fig. 19—Bulldozer, as used in the Rambler plant for pressing crossbars and other parts of flat steel

Bulldozers Coldpress Crossbars—Unless chassis-frame crossbars are very intricate in shape they are coldpressed in bulldozers, one of which is here presented as Fig. 19, and, as will be observed, half of a die placed against an abutment, the latter formed from the mass of metal in the frame, and the pressure needed is obtained by double sidecranks, which connect to a crossmember which carries the other half of the forming die. Power is utilized in driving the bulldozer on a considerably less scale than might be supposed, due to the work coming on for a part of the revolution only, and flywheel effect is taken advantage of to accumulate energy, the same to be expended when the work is being pressed. When the shapes are very intricate, or if the material used is alloy steel, as it is in some crossbars, the work is done hot. The bulldozer in the shop is responsible for the elimination of castings in automobiles to a considerable extent, and this particular size, besides pressing crossbars, is used for many other purposes as well, one of which may be seen in the figure, in which the particular operation consists of bending a piece of drawn steel tubing for use in fitting up a motor.

Vertical Types of Presses Lend Facility—Perhaps there is no better application of a vertical type of press to be had than the one shown in Fig. 20, which is doing broaching work; broaching a square hole by pressing a broaching tool through the round hole in a part to be so fashioned. Broaching square holes to any great extent is a modern idea brought about by the coming of the automobile, in which there are several square shafts, notably in the transmission, in connection with the sliding gears. In this particular case, owing to the power of the press the broaching is done with great speed, and by the use of special high speed steel in the broaching tool it is made to sustain, even though the tool is pressed through a considerable mass of material to be removed, and at a rapid rate.

Hydraulic Press Has Many Advantages—The hydraulic press shown in Fig. 21 is operated on flywheels pressing one on to the crankshaft, the shaft being tapered to receive the flywheel, and in the process the press applies a force of some fifteen tons, the exact pressure depending upon the accuracy displayed in the machining process. In this class of work the press is the best inspector possible to employ, for if the pressure falls below a certain point it will be appreciated that the fit is below the requirement; likewise, if the pressure goes up too much there is danger of splitting the hub of the flywheel, so that in all truth the man at the press is one of more than a little intelligence in the shops that do the better class of work. This is an excellent illustration of working on a large scale.

HEAT TREATMENT AUGMENTS KINETIC QUALITIES

In visiting the plant of the Diamond Chain Company, at Indianapolis, Ind., opportunity was afforded to note something of the extent to which qualities in steel were accentuated in heat treating. In side chain drives, which are on the increase, by the way, due to the large number of the better class of runabouts and other small cars, which are being put out with chain drives, not forgetting that trucks, now being built in quantities, almost invariably use chains, opportunity is afforded to bring the material used up to the highest possible state, partly due to the necessity of using high kinetic material, and again in view of the shapes of the parts, which lend facility in the process.

In this work, as it is conducted at the plant above named, the process of heat treatment is carried on in a large way, and Fig. 22 presents a corner of the room showing a battery of "salt" furnaces, they being used for the better grade of work, especially in annealing. Fig. 23 shows cementing furnaces, of which there are a large number, they being used to give a depth of carbon, the same having the facility of rendering the surfaces glass hard, leaving the core soft—so soft, in fact, that it is highly kinetic and acts as a cushion for the shell.

Instruments of Precision Guide the Artisans—Referring to Fig. 24, P1 is a pyrometer, used to determine the temperature prevailing in the respective furnaces, S1 is the electric switch used to connect up the pyrometer, R1 and R2 are rheostats used to regulate the voltage of the circuit in calibrating the pyrometer, T1 is a thermometer used to determine the temperature of the baths, T2 is a thermometer which gives the surrounding temperature, and P1 is a pressure gauge which reads pressure of the circulating air, which is of the greatest advantage in refrigerating and mechanically agitating the quenching baths, they being heated up by the heated parts when quenching is being done and it being necessary to maintain the temperature at a constant level, it being also desirable to brush off the globules of steam or vapor of oil, as they adhere to the parts; this desirable operation is brought about by agitation of the liquid, which transpires when the compressed air is liberated below the surfaces of the bath.

ECONOMIES FROM TWO POINTS OF VIEW

Instead of economizing by purchasing inferior materials for use in parts, it is now the practice in the plants of note to

Fig. 20—In the Rambler, broaching square holes, using broaching cutters in a vertical press, working at high speed

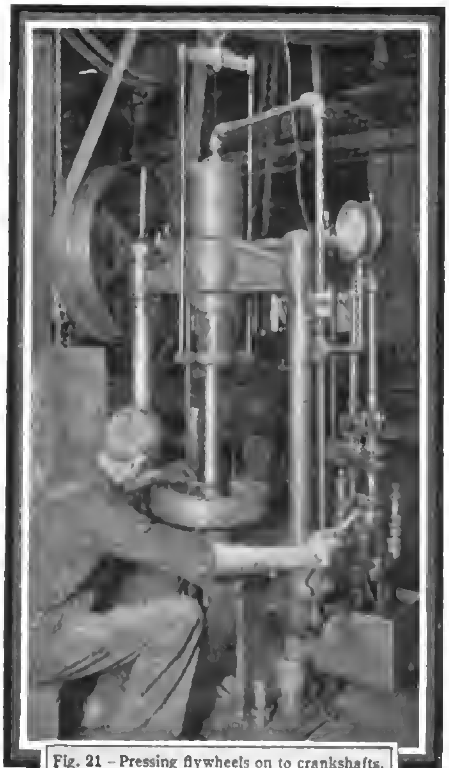

Fig. 21 – Pressing flywheels on to crankshafts, using about fifteen tons pressure and a hydraulic press

economize in divers other ways, as in the use of material and by stopping of wastages. Fig. 25 presents a corner in the plant of the Diamond Chain Company where product is weighed, the platform scales S1 being used for the purpose, and as the chips and turnings accumulate they are put in the separator O1 if they are small, O2 for other grades, and the large turnings go into the separator S2, where the entrained small parts are separated out and all lubricating oil is taken away, leaving the turnings dry and delivering them into a bin which is placed outside the building adjacent to the roadway, so that the delivery of this product is cheaply and promptly made. The recovered oil from these separators is used over and over; it represents a large item, and the value of the turnings, chips, etc., is reduced to the right level.

MULTIPLE WORKING OF OPERATIONS

One of the very distinct ways by which quantity is being turned out without reducing quality lies in the utilization of machine tools which have been so contrived that a plurality of parts are finished at one time. Fig. 26 of a multiple operation shows a gang of saws cutting off "blocks" as used in block forms of Diamond chains, delivers 27 blocks from the bar at one time and in about three minutes; this is certainly high speed, especially considering the dense quality of the material used in these chains.

Continuous feeding makes for output, and the quality, if anything, is improved. Fig. 27 shows a specimen of this class of work, in which a hopper H1 is loaded with links which feed down on to the revolving platen P1, on which the operator places the rivets from the tote pan R1 and the process of assembling is continuous; this is one of the many tools of this character which makes sprocket chains possible, it having been worked out in the plant of the Diamond Chain Company in the manner as here shown.

FEMALE LABOR IS NOW BEING UTILIZED

To a greater extent perhaps than is generally realized female labor is taken advantage of in the several plants. There seems to be no limit to the work that can be placed in the hands of competent working women, and Fig. 28 is illustrative of the point to be made. In this instance a long line of buffing and polishing machines (only one shows) are doing the fine finishing work on chain parts in the Diamond plant, and from information at hand it is apparent that this venture is an entire success. In almost every automobile plant, especially where tops and upholstering is done, women take a hand, doing much of the better class of work to be seen in the artistic creations of the present day.

MACHINE MADE WHEELS MUCH ADVANCED

In the earlier attempts to make wheels of wood by machinery they fell below a certain standard, partly due to lack of completeness of method, and again in view of a certain hostility on the part of wheelwrights, they having the erroneous impression that the growth of machinery for this class of work would belittle their efforts. Fig. 29 depicts the process employed in truing up wheels, in which W1 is the wheel on the vertical spindle S1, and the abrading disc D1, being rotated by means of power furnished by the belt B1, sands off the high spots, bringing the felloes down to the right diameter for the rim. If the wheel is out of true, a point now regarded as fatal to good results, the plate S2 will show, and the operator governs himself accordingly.

Fig. 22—Salt furnaces, used in heat treating work at the plant where Diamond chains are made

NOISELESSNESS IN GEARS NOW DEMANDED

In former times it was the rule to reduce noise produced from gears as much as possible and then explain to the purchaser that noise, to some extent, was to be expected. This year things are different; noise is eliminated and silence reigns. How this was brought about is a long story to be sure, but it is worth a moment here to intimate something of it.

In some plants, and in dealing with bevel drives in order to eliminate noise, they are annealed between every forging operation, machined exactly to size, then copper-plated before being gashed and very carefully cut, using the Hugo Bilgrim or other refined methods, by which the teeth are accurately planed to the theoretical right shape. The copper plating which is done before the teeth are cut serves as a shield, preventing the carbon from penetrating below the surface in the cementing process, excepting where the copper plating is afterwards cut away, and as a result the cementation is limited to the very surfaces which are to be rendered hard. The advantage in this is noticed in subsequent treatment, when it is the aim to harden the teeth and at the same time prevent warping. Deformation is but slight, if any, under these conditions, and noiselessness is the result.

When the gears are all made for any given lot they are then measured and a process of matching up is entered into, it being the desire to ascertain by actual trial in a measuring machine the most noiseless condition, and by matching up this condition is arrived at.

While it is true that noise is reduced to almost a mere suspicion when the gears are well cut, provided the spiral-tooth formation is used, and especially when the "herringbone" idea is incorporated in, even so, no matter how well the work is done, or what the shape of the teeth may be, if the pitchline velocity is beyond a certain speed, noise is likely to be generated, and under such conditions, in order to eliminate the noise, the gears are "leaded."

The process of leading is best carried out when the flange (below the roots of teeth) are undercut and then filled in by casting a rib of Babbitt around the inner periphery of the gears. This layer of Babbitt, even though it may not be so very thick, will kill noise most effectually. To show something of how this work is carried on, reference will be had to Fig. 30, of a battery of gear cutters, and Fig. 31 is assembled transmission units, as taken for the author at the plant of the Warner Gear Company.

In going through the several plants and in discussing the matters with makers of machine tools, the conclusion is reached that the automobile has modernized processes to a vast extent, and among the builders of note, principles are very much alike. Fig. 32, for illustration, presents a method of broaching square holes in sleeve gears, the process being rapid and accurate. In spiral half-time gear making, the idea being to eliminate noise, the gear cutters are of the highest order of merit, one of the finest examples being that as shown in Fig. 33, as used in the plant of the National Motor Vehicle Company at Indianapolis, Ind.

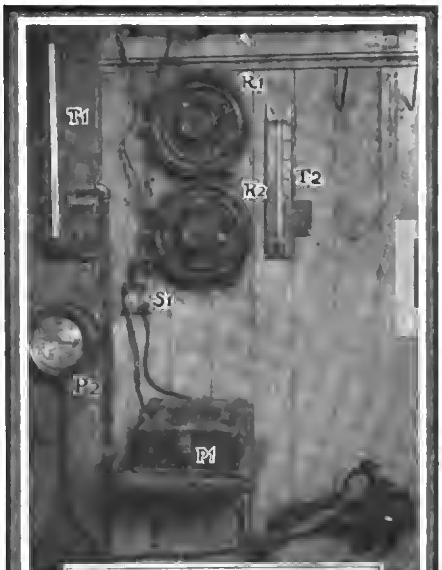

Fig. 21 Pyrometer, thermometers, rheostats, pressure-gauge, and other equipment used in heat treating Diamond chains

SHOP TRANSPORTATION BEING LOOKED AFTER

While traveling cranes are used to some extent, especially in the plants devoted to the manufacture of high-powered motors, even so, considering the run of automobile plants and the fact that the largest units weigh less than 1,000 pounds as an outside figure, other methods obtain for the most part. Industrial railway systems using the "Hunt" narrow-gauge standard of track building, which is 21 inches, with a scheme by which the longest cars are capable of rolling around a curve of 12 feet radius as easy, according to C. W. Hunt, "as a wagon rolls around a corner."

These tracks come made up, and are laid flush in the concrete floor, hence serving their useful purpose without impediment of

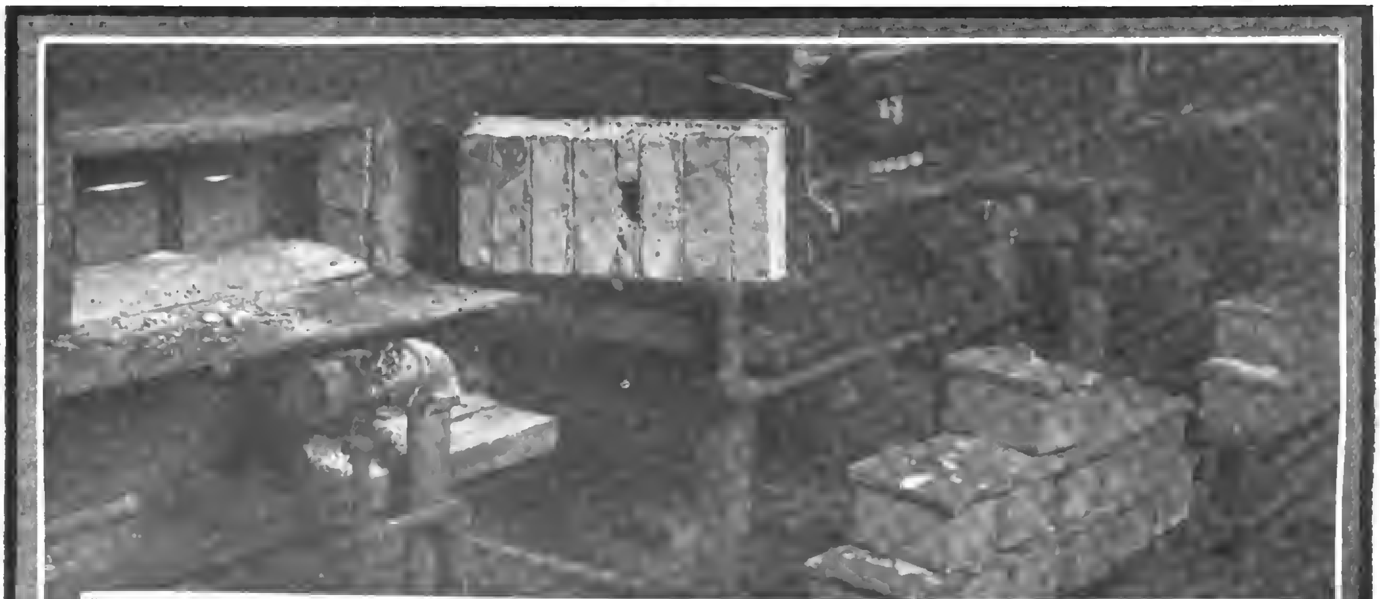

Fig. 23—Cementing furnaces, as used in the manufacture of Diamond chains, to make surfaces glass hard, leaving cores soft

Fig. 26—Special gang-saw, cutting off 28 blocks at one time, as used in Diamond block chain

any kind, and the cars, as usually made, come in several lengths, ranging from 6 to 14 feet over the platform. The cars, being designed for easy pushing when loaded, are mobile in the extreme, even when being pushed with a full load by a single laborer. Tote pans made of pressed steel are used to keep the work separate, especially the small parts, and these pans are loaded on to the cars as the operations are completed, when the laborer pushes the cars along to the point of delivery. Small electric locomotives are also available for use in the larger shops.

Other Methods of Transportation in Vogue—Besides tracks and cars, there are systems of overhead trolleys by means of which motors are picked up and whisked along, one of which is being used extensively in the Rambler plant at Kenosha, Wis. Then there are portable pulley block cranes which do excellent work in motor assembly rooms, one of which is illustrated in Fig. 34, which is a type as made by the Cameron Engineering Company, New York City.

In some of the larger plants, adjacent to sidings, tracks are laid right into the shipping departments, and as a general rule the siding passes by the receiving room. This is a positive advantage in that materials may be landed on the floor, under the crane, or beside the equipment used for moving materials in the shop. The overhead charges, which must go against the output cost, whether it be automobiles, parts, or accessories, will be less in the plants which are fitted out for good transportation than will be true of the remaining plants, and this year, if signs count, every effort is being made to keep down overhead charges and put additional quality into automobiles. The cost of selling an automobile is lower when the quality is superior, and it is in the cost of selling that economies will have to be made.

SANDBLAST TAKES PROMINENT PART

In former times, owing to the habit of keeping in a groove, which according to competent authority differs only from a grave in that it is longer, pickeling was practised almost to the entire exclusion of sand blasting and drop forgings, for illustration, were frequently neglected. In the course of time, due to protracted investigation, it has been found that even the very best drop forgings may not be relied upon unless they are given a critical examination, even when annealed, and in the absence of annealing they lacked requisite qualities to a marked degree.

This year as never before drop forgings are in vogue, and, they being turned out in vast quantities, the question of annealing became of even more importance. Nearly every up-to-date maker of automobiles therefore, besides installing an annealing battery, added a sand blast in order to be able to quickly remove the skin of the forgings, thus enabling the inspector to see the surfaces and to note if they are free from blemishes. There are other important advantages to be attached to this question of sand blasting, as, for illustration, the parts anneal better and surface strains are thus removed more readily.

ANNEALING DONE IN DIVERS WAYS

When parts are at a high heat, if they are then exposed to the atmosphere they will oxidize, and in order to avoid this when annealing, in some of the well-equipped plants, the parts are placed in a "gas" annealing oven, in which illuminating gas is allowed to enter, thus driving out the atmospheric air, with its oxygen, hence oxidization is prevented and as a result the forgings are less troublesome to finish, and, besides, they have a better look. In sidebars, as used in chassis frames, this is an important matter owing to the thin metal used in them, thus making it undesirable to have any of the metal oxided away, as it would be were the annealing conducted in the open air.

In quenching baths, in order to maintain them at a constant temperature, which is desirable, they are cooled by allowing compressed air to enter, having the compression up to the refrigerating point, which is above 60 degrees Fahrenheit, and the same air, since it agitates the liquid, drives all bubbles of vapor from the surfaces of the parts undergoing quenching, and the results are far more uniform. This method is used to excellent advantage in the plant of A. O. Smith Company, at Milwaukee, Wis., in the process of making chassis members, which class of work is done on a tremendous scale at this plant.

PRODUCES GAS PLANTS USED

Power to run the large plants devoted to the manufacture of automobiles represents a large item in the overhead costs, and in the West in particular producer gas plants. utilizing gas engines, are rapidly taking the place of steam engines, boilers and their accessories. The plant of Wheeler & Schebler, makers of Schebler carbureters, at Indianapolis, Ind., is run in this way, and with the new addition, which is now well under way, a large pro-

Fig. 25—Economy inducing equipment, used at the plant of the Diamond chain to recover oil and dispose of turnings

ducer extension is being made, which is evidence of satisfaction given by the old plant. At the new plant of A. O. Smith Company at Milwaukee a very extensive producer battery is being installed, the entire and only source of power being from a producer system. Power of this sort is also used at the extensive plant of the Rambler, at Kenosha, and as a matter of fact there are divers other illustrations of this growing method of supplying power, in which the space required, labor of maintenance and fuel consumption seems to be lower than that possible when conventional steam methods obtain.

INSTRUMENTS OF PRECISION DEPENDED UPON

Interchangeability of parts, being the far cry, demands precision of method, and this in turn must be at the expense of instruments, facilities and the class of men who appreciate their proper use. Makers of measuring instruments, appreciating this, have produced for such use divers instruments, all of micrometer characteristics, and in many instances the principle of the "extensometer" is embodied by means of which the ten-thousandth of an inch may be read off as readily as it was before to read to thousandths. These instruments, in conjunction with jigs, fixtures and method, such as illustrated in this article. has done more to make automobile parts interchangeable than any one thing excepting the demand of the American autoist for first-rate automobiles.

Fig. 28—Women, occupy a place of worth, performing responsible operations, in the manufacture of Diamond chains

ROAD TESTING VALUE

Some of the companies give the cars made an actual road test of approximately 100 miles, and in this test it is the aim to abuse the cars, thereby breaking any parts which may not be up to the required strength. This test is in addition to such shop tests as are required to render the product uniform in character. In other plants, due, in a large measure, to a difference of opinion as to the value of a road test, this abuse test is dispensed with and every effort is made, in the shop, to fix the standard of quality, even to the extent of testing every lot of material used, to quite some extent, in the laboratory.

The mere fact that an abuse test is given is not, insofar as can be seen, reason for slighting the shop tests, nor is it believed that the companies who do resort to the abuse test slight the other methods. Of the plants visited, those which practiced the road test of all cars made, also run a laboratory, and that laboratory methods obtained to a vast extent was seen. Whether or not the road test is desirable is a matter that must be settled in time, yet even so, it does seem as if trouble, if such there is, should fall to the makers, which it probably will if a rigorous test of 100 miles is actually made under severe road conditions.

ELECTRICAL TRANSMISSION OF POWER

As never before, the transmission and distribution of power, in the shops, to the respective machines is being accomplished by utilizing electric motors, and in many of the most important cases individual motors are being much used. As a rule, how-

Fig. 27—Special assembling tool, fitted with a hopper, by means of which the work is fed continuously in assembling Diamond chains

ever, with a view of realizing a good average efficiency, at a reasonable first cost, mixed systems of distribution prevail, in which groups of kindred machine tools, as drill presses, for illustration, are run from a countershaft, and this shaft, in turn, takes its power from a single electric motor.

The power house, for divers reasons, should be placed at a

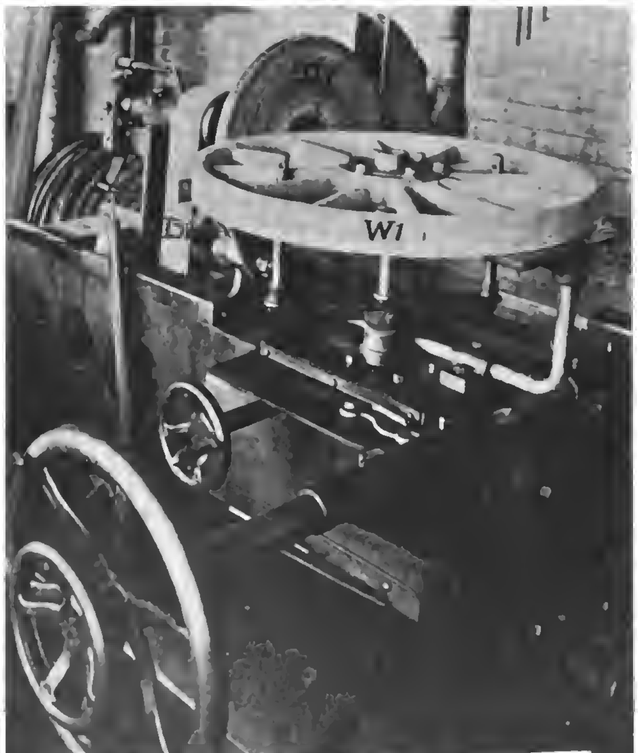

Fig. 29 Modern wheels to be true, and to size, are trued up in a machine as here illustrated

Fig. 30—Bank of gear cutting machines in the plant of the Warner Gear Company, of which there are many

distance from the main buildings, and this is rendered possible when electric methods of transmission are taken advantage of. With the power house at a distance the fire hazard is eliminated to the extent that if a wing of the main buildings is lost, the power plant will be intact.

In the power plants, as they are being fashioned, if steam is used, coal is handled economically by means of stokers, and the labor item, as well as certain labor complications are placed below a shut down for lack of power. The electric wiring systems, to the greatest possible extent, are run free of the buildings, it being the idea to abort an interruption of service in the balance of a plant if, perchance, a wing should take fire.

Direct Current Most Used—In the distribution of electrical energy for power purposes, the several electrical problems have been worked out to a high state of efficiency, and, while alternating-current work is, to some extent, to be seen, yet even so, users seem still to have a strong preference for direct-current motors. If the power is taken from a central station, which, in some cases, is true, the source may be alternating, but, in the shop, rotary transformers are then employed and the motors remain direct current.

The power actually used by a considerable number of motors, as distributed in a shop, is far below the total of the motor ratings. It has been found that the source of electrical energy, as the dynamo equipment, will scarcely have to be more than about 25 per cent of the sum of the ratings of the motors used in the plant, even assuming that each motor is loaded to its full capacity at times during the day. This is an important point well worth taking into account when plants are being installed, and, while 25 per cent is not exactly right, yet even so, the worst condition is scarcely above 33 per cent; the exact percentage depends upon the number of motors and the total power capacity of them.

In determining upon the extent to which individual drives should be indulged in, the several automobile builders consulted their pocketbook to the extent that the first cost is higher, and, having satisfied this phase of the problem, they then considered that a machine, if it requires less than one horsepower, maximum, to run it, might well be grouped, as a rule. The commercial efficiency of a motor, if it is wound for less than one horsepower, is considerably below 75 per cent, and, economy being the great factor, the commercial efficiency of the motors must be considered.

How Fire Risk Effects Parts Plants—When an automobile maker places an order for parts he is much concerned about deliveries, and since all contracts terminate with a fire, it is up to the purchaser to place his orders with the class of parts makers best protected against fire. Some companies, when considering the placing of orders for parts or accessories, indicate a willingness to pay more if the fire risk is reduced to near zero, as it is in many cases. In other cases it is the settled policy of the companies not to place an order unless the building in which the work is to be done is absolutely fireproof. The Timken Roller Bearing Company, for illustration, is authority for the statement that none of its materials, as used in its products, is purchased from any source unless the building in which it is made is absolutely fireproof and a sprinkler system is installed.

Saw-tooth Buildings are Fireproof and Light—Many of the most modern plants devoted to the making of automobiles are of the saw-tooth variety, or variations thereof, and modern cement construction. Good examples of these types of building will be found at the Inter-State, Hupmobile, Rambler, Mitchell, National, Oakland, Pierce, Premier, and others. One of the very largest,

Fig. 31—Lot of transmission gears ready to box and ship from the plant of the Warner Gear Company

and perhaps, the most imposing of the newer buildings of the year, is that of the A. O. Smith Company, at Milwaukee, which is about ready for occupancy, and will be devoted to the production of chassis frames and parts, also transmissions, steering gear, brake drums, and, in fine, everything that pressed steel will shape up to as used in automobiles.

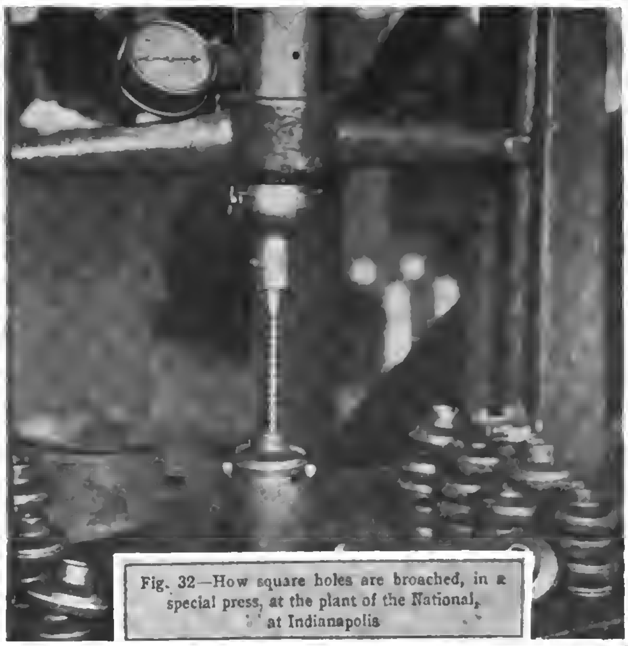

Fig. 32—How square holes are broached, in a special press, at the plant of the National, at Indianapolis

USES OF AUTOMOBILE TYPES OF MOTORS

Besides the regular use to which the automobile motor is put, in propelling automobiles, and, not mentioning aerial propulsion, there is still another zone of activity which it is expanding at a very rapid rate. Prior to the advent of the automobile, attempts were made to run plants and do electric lighting, using gas and gasoline types of internal combustion motors in the process. The motors, while they run with a certain ratio of facility, failed, for the most part, owing to interruptions in service, which seemed unavoidable, owing to the lack of good control of the motors.

This last year, as it seems, particular advances were made; motors, for stationary work, are more nearly in accord with practices in automobile engineering, and in many of the plants devoted to the manufacture of automobiles or accessories, internal combustion motors are employed, in some cases for power in general, and in many instances for lighting, in which the lighting dynamo is driven by a four-cylinder automobile type of gasoline motor. True, in the better examples, as at the plant of Wheeler & Schebler, at Indianapolis, the gasoline is eliminated and a suction producer system of gas making is used instead.

In view of what has already been done, and considering the extent of activity now to be noticed, it comes as a pleasant duty to report something of the progress which is being made, progress, in fact, which assures that internal combustion types of motors are now claiming a fair share of the attention of the most advanced engineers who make a specialty of power transmission, considering carefully the thermal efficiency of the power plant proper.

Gasoline-Electric Generator Sets—Perhaps the most notable advance, which will count in the long run, is in connection with the relatively new attempts, on the part of manufacturers of electrical machinery, to build gasoline-electric generator sets, they being in the several sizes, ranging from a generator used to furnish power for a searchlight to the largest sizes, as required for lighting and power, in plants of pretense. Among the particular advances which were made in this field the generator sets now being offered by the General Electric Company, Schenectady, N. Y., are worthy of particular notice. These sets are made in several sizes, one of which having an output of 25 kilowatts, with an overload capacity of 25 per cent.

Compactness is a striking feature in these sets, and in plants where space is valuable, this phase of the situation becomes of more than a little moment. The labor problem is much simplified; it takes but a few moments per day for a man of just a little skill to keep this class of equipment in working order.

Charging Storage Batteries Considered—In these days, when electric vehicles are becoming more numerous than flies, as it were, the question of charging stations, at well regulated points all over the land, is being taken up and struggled with. The method of driving the charging dynamos has to be reduced to finality in the long run, and there is probably no better way from any point of view than to employ just such a set as is here referred to. A licensed engineer will not have to be placed in charge of the plant; space required is much restricted; efficiency is favorable, and the regulation is all that this class of work requires.

A 25-kilowatt generator set will easily handle 12 batteries at one time, and charging 24 hours per day, which is the most economical way to do this class of work, makes it possible to charge fully 36 vehicle batteries at one time, even if each battery must be on charge for eight consecutive hours, which is not usually the case. Just how many batteries would have to be fully charged each day is difficult to state, owing to the influence of locality, character of service, and other details. In private service, as with cars owned by individuals, a 25-kilowatt generator set would be ample for fully 100 electrics. In cab

Fig. 33 Spiral half-time gears, made noiseless in operation by the method, as shown, at the National

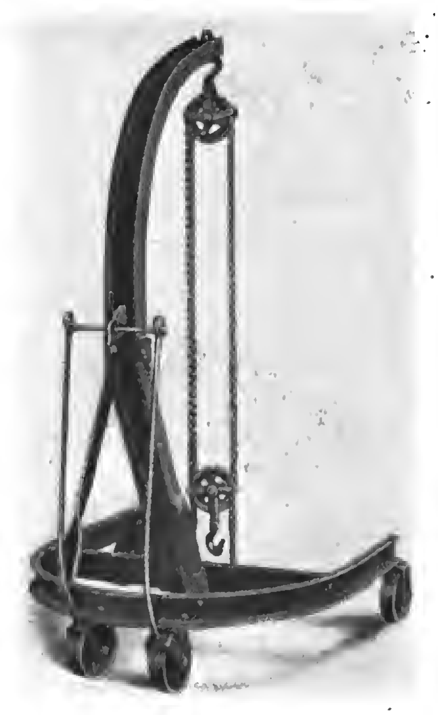

Fig. 34—Portable pulley block crane, made by Cammeron Engineering Company, used in shops for handling motors, etc.

service, owing to a peak load as night approaches, not more than 40 cabs could be handled, unless, in connection with the generator set, a storage battery is employed, the same being used to absorb the excesses from the generator set, during the hours of each day when the vehicle batteries, on charge, might fall below the capacity of the set.

In running a generator set 24 hours per day, it would be feasible to take advantage of the presence of a night watchman, who, in view of insurance requirements, must be present, in any event. The skill demanded would not be beyond that of a man of fair intelligence, as a watchman, if he is worth relying upon at all.

GENERAL ELECTRIC PORTABLE DRILLS

Besides the types of direct-current portable drills that have long served in shops, especially in the department in which chassis frame and assembling work is done, there is now to be had, when the conditions require, types of alternating-current portable drills, which are efficient and capable. In some plants, owing to taking current from the central power companies, direct current is not available, and while electric motors may be run with good facility, and lighting may be accomplished, using alternating current, even so, in the past, the question of portable drilling was not in such good shape, and, in view of recent advances made in this field, it is pleasurable to note that this phase of the industrial problem is now well in hand.

Electrical Energy Required in Drilling—Considering machine steel, which is about the hardness of chassis frames and like work, the electrical current required is about as follows:

CONSIDERING THE SEVERAL SIZES OF DRILLS

Size of Drill	Time Required	Watts Taken	Current in Amperes
1-8"	30 sec.	110	1.3
1-4"	28 sec.	150	1.7
3-8"	95 sec.	200	2.15

Motors are regularly wound for a 60-cycle circuit and are capable of delivering something over 1-5 of a horsepower. The line current and input in watts are nearly parallel, and the power factor increases to slightly better than 90 per cent. at a little over half load. It is about half load that the motor must work in the average undertaking, and, under such conditions, the motor has an ample reserve of ability, heating is well in hand, and the power factor is at a favorable point.

Electro-dynamometers Much Used—In testing motors, in the respective shops, electro-dynamometers are now almost standard, they being, in principle, as shown in Fig. 35, in which A is the armature of the electric machine, B is the separately excited field winding over the pole-piece, of which there may be any even number (four, six, or eight being common), C is the field, and serves also for the frame. D represents one of the pedestals of the cradle, there being one at each end with bearings for the armature spindle, E represents counter weights, F is the arm, G is the platform of the scales, H is the beam of the scales, I is the field rheostat by means of which the strength of the field is altered to suit the requirement, and J is the rheostat, or other suitable means, by which the energy of the dynamo is disposed of. A bank of lamps, or water rheostat, usually takes the place of J. The armature must be wound, and of a size, to deliver about 600 watts per horsepower of the motor to be tested, but the voltage may be any desired value within practical limits. The figure is merely diagrammatic, and, in practice, there are several compact forms of electric-dynamometers to be had, and at reasonable prices, considering the value of the method. At the Rambler plant, a somewhat different method is in vogue, which was described in THE AUTOMOBILE, issue of December 23, 1909.

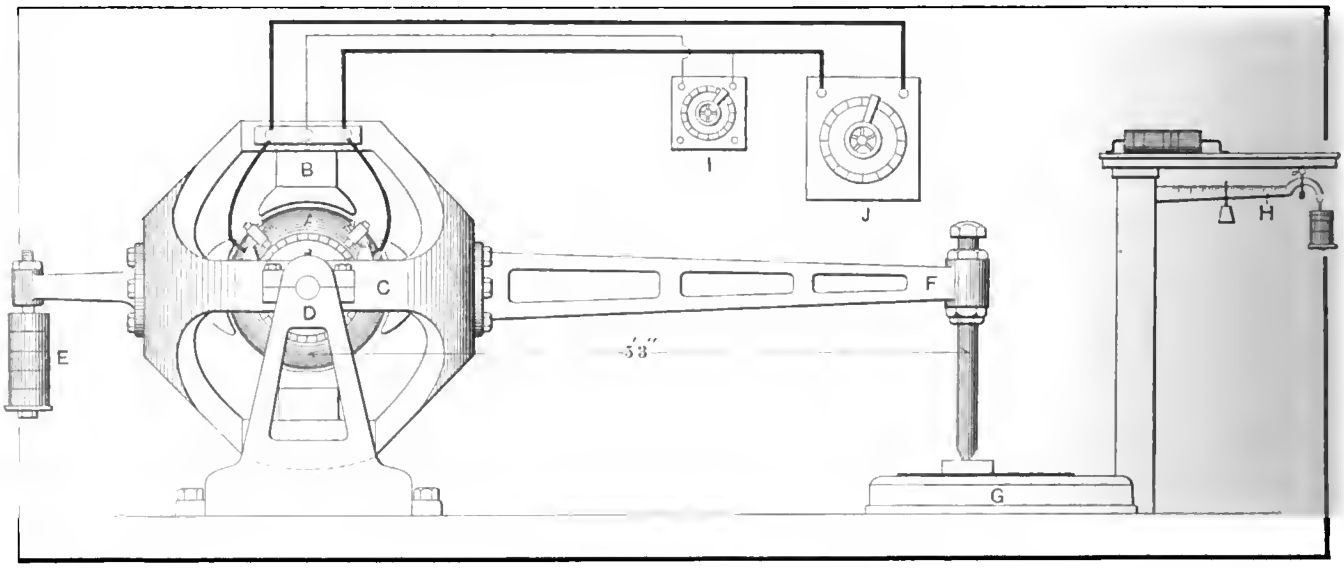

Fig. 35—Diagrammatic representation of an electro-dynamometer, as used for testing automobile motors, of which there are divers modifications

Advanced Mechanical Features That Prevail

By Thos. J. Fay

TAKEN at random, some actual working drawings from which the automobiles as they are to be displayed at the Grand Central Palace were made, these drawings having been placed at the disposal of the author for publication, it will be possible to make a definite showing, much more so, in fine, than in any other way, particularly since the very cars on exhibition were examined during process of manufacture by the author, and at some length. Unfortunately, it will be impossible to reproduce more than a fraction of them, nor is it true that those reproduced make for more than representation of the situation in general, which it is the purpose here to reflect.

Safety Has a Large Share in Present Practice—It will be the purpose here to reflect, by illustrations and otherwise, the extent to which safety is uppermost in the minds of designers, and it is just this safety that accounts for the diminished list of accidents which statistics indicate. While the number of automobiles actually in commission have increased this last year to an enormous extent, the list of accidents has gone up but slightly considering the increase in the number of automobiles running.

Better brakes, superior clutches, advances in materials and a closer relation of the designer to the product account for improvement in this direction, and, considering the advances made, legislation of the rabid sort will soon be out of place. In many ways racing has played an important part, this method of testing out cars having the faculty of locating the little as well as the prominent weaknesses in automobiles.

While it is true that cars are this year more than ever the product of parts establishments, it is equally true that parts makers are more inclined to have their own way when reference is had to quality. It is now the settled policy of parts makers to grow a reputation which will serve as an asset in future, and they recognize the utter impossibility of doing so if they merely follow specifications, provided they reach the conclusion that the specifications are for inferior products.

Facings Used in Clutch Work—This year, in view of improvements in materials for facing clutches, there has been a distinct movement in the direction of dry-disc clutches, using but a limited number of discs and either cork inserts or asbestos fabric in the facing. Of the cork insert types nothing more will be said at this time, but of the asbestos fabric it may be well to refer to it in somewhat definite terms, giving results of a test or two, which will show that the claim for lasting qualities under heat and pressure is well founded.

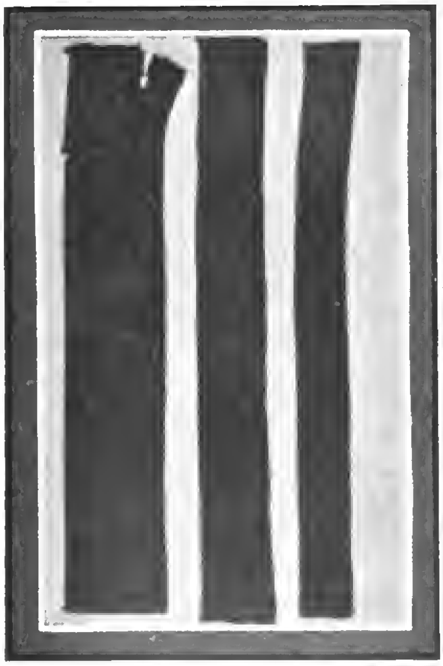

Fig. 1—Physical test of Raybestos, proving tensile strength

Fig. 1 is of some of this fabric, which was pulled in a testing machine at the large plant of the Pierce-Arrow Motor Car Company, with results as follows:

Thickness in inches.	Width in inches.	Ultimate Strength in pounds.	Thickness in inches.	Width in inches.	Ultimate Strength in pounds.
7.32	1½	900	7.32	2	1,280
7.32	1½	960	7.32	2	1,360
7.32	1½	840	7.32	2	1,200
7.32	1½	990	7.32	2	1,480
Approximate average ultimate strength, 2,743 pounds per square inch.			Approximate average ultimate strength, 2,876 pounds per square inch.		

Fig. 2 is of the same material after it was "fired" to determine its heat-resisting qualities, which proved to be satisfactory up to 1,110 degrees Fahrenheit; the material was still strong.

Fabric, taking advantage of the heat qualities of asbestos, is rendered strong by having the asbestos interwoven with copper or other suitable wire mesh, and it has been determined that the coefficient of friction of this material is not far from 0.25, which is considerably better than that of any of the higher grades of leather used in this class of work.

In some cases, to afford immunity from the ills of excesses of lubricating oil, cork inserts are used in conjunction with asbestos fabric, and when the design is happy the results are of a permanent character. Leather alone in cone clutches, if it is properly backed up by means of springs, seems to be entirely feasible, and many of the cars adhere to this plan. As it stands, then, for this year, clutch facings are quite well divided between:

(A) Leather, in cone clutch work.
(B) "Cork Inserts" alone, and with leather or asbestos fabric.
(C) Asbestos fabric.
(D) Steel on steel, lubricated or dry.
(E) Steel on bronze, to some extent.
(F) Steel on cast gray iron.

Clutch spiders are largely of aluminum, but the metal used is on a better footing than formerly, it being the settled policy to avoid the use of "scrap" in the process and demand ingots of far greater purity than formerly. The shapes of the spiders, as the illustrations herein given will show, are for strength, in the absence of great weight, and in sliding gears the effect of inertia is not so much to be noticed as on former occasions, when the weight of the spider was far greater than now.

Refinements in Clutches Noted—Tried methods seem to be in favor, and few indeed are the absolutely new clutches to be seen. It is very likely that the clutch, Fig. 3, just brought out by the Elkhart Motor Car Company and applied to "Sterling" automobiles, is the latest idea, in which driving is done through the shell A. in conjunction with its mate B, and in operation the wedge shaped member C,

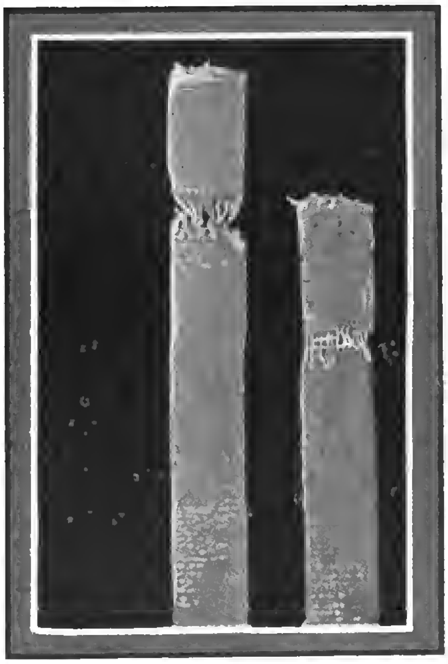

Fig. 2—Heat test of Raybestos, indicating heat-resisting qualities

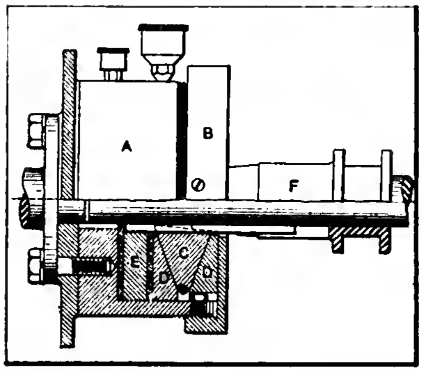

Fig. 3—New form of clutch, which is reported to perform with great precision

which embraces 90 degrees of arc, is moved toward the periphery of the adjacent disc by travel of the tapered sleeve F, thereby expanding the discs E, binding it between the base of the clutch and the member D. Red fiber is used as the friction material, this being a detail which may be altered to suit the individual.

Multiple Disc Clutches Being Improved—The best indication, perhaps, of improvements being made in multiple disc clutches is that as presented in Fig. 4, which is a driving member in Premier practice, the disc being of sawblade steel, properly heat treated and so contrived that the lubricant, if such is used, will be scraped away from between the discs at a rapid rate and the discs will spring apart when the tension of the spring is relieved. In actual practice in almost every instance oil, for purposes of lubrication, is not used, and the Premier Motor Manufacturing Company, Indianapolis, Ind., is authority for the statement that lubricating is not particularly desired; the clutch works dry usually for a longer time without attention of any sort. Fig. 5 is of a driven disc in Premier practice, in which it will be observed that the driving faces are liberal; this disc is also of steel, so that the drive is steel on steel, preferably not lubricated.

Clutch and Transmission Combined—Multiple disc clutches lend facility to the process when it is desired to place the clutch within the gearcase, as is done in the Inter-State Model 40, as shown in Fig. 6, and since the whole case is substantially cylindrical, strength is assured. The discs are lubricated in a very simple fashion, assurance being present of no lack of oil, since it is held in the case in excess. The service rendered by this system is sufficiently conspicuous to warrant one in predicting that it is one of the types that will survive for all time.

Brush Runabout Has Compact Clutch—The idea worked out in the Brush Runabout is to be commended, for this clutch, while it is of the multiple disc type and within the transmission case, is really a set of discs clamped between a set of vise-like jaws when the clutch is "in." The excellent work this type of clutch is doing rather goes to show that it is quite capable enough for general exploitation, and it is one of the features which has made the Brush Runabout all that it has proven to be.

Jackson Multiple Disc Clutch Simple—Referring to Fig. 7 it will be observed that the clutch in the Jackson, made by the Jackson Automobile Company, of Jackson, Mich., has three plates, they being of large diameter, actuated by a toggle motion in which pressure to the maximum is exerted at will by the operator, and lost motion, if it is generated in time, due to wear, is readily taken up by the means provided. In this clutch the plates are separated by the springs B, and the discs are prevented from rotating by the torque bolts A A A. For taking up lost motion all that is necessary is to undo the capscrew D, screw up on the shell enough for the purpose, and tighten up the capscrew again to lock the system in place. The toggle system C will require no discussion, it being exactly the same as has worked for years on the best types of locomotives in connection with the very powerful brakes demanded in express service.

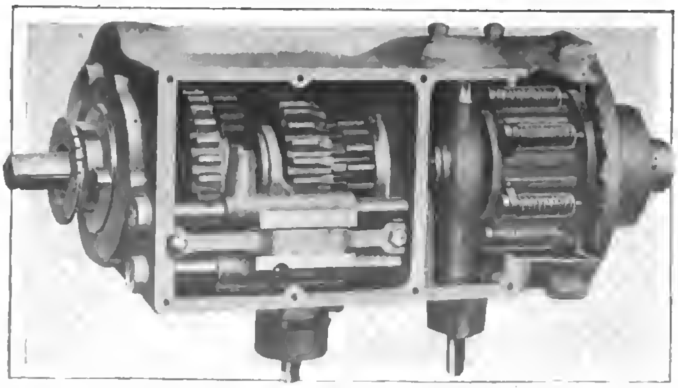

Fig. 6—Inter-State type of multiple disc clutch, housed in transmission case and profusely lubricated

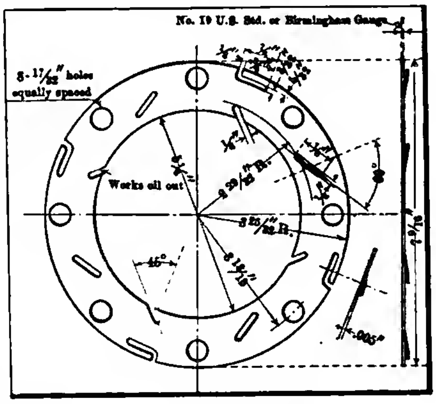

Fig. 4—Premier form of disc, designed to work well with or without lubrication

National Cone Clutch of Great Simplicity—Fig. 8 is a section of the cone clutch with a leather facing, L1, and flat springs are placed under the leather around the periphery for the purpose of pressing the leather into proper engagement. The clutch is flanged, F1, and a long bearing, B1, serves to maintain concentric relations. The square spring S1 presses the clutch into engagement, and adjustment is secured by pressing the thrust block of the ball type up against the other end of the spring. Thrust is equalized by means of the ball thrust-block T1, and the universal joint back of the clutch J1 occupies a dual capacity, in that it compensates for flexure and takes up endwise motion.

Cork Inserts Found Beneficial—In many cases, especially in cone clutches, but not limited to them, cork inserts are used in the manner as shown in Fig. 9, which is a type of cone clutch as made by the General Manufacturing Company for several of the well-known makers of automobiles. The clutch in a general way is of the conventional sort, the only difference being that the periphery, as well as being provided with the leather facing, has cork inserts, as patented by the National Brake & Clutch Company, of Boston, Mass., spaced in sockets around the periphery. The cork affords a better coefficient of friction, works in oil as well as dry, lasts for a long time, as is proven in Premier brakes, and prevents the leather from burning out.

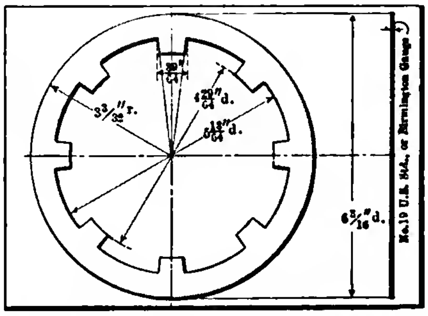

Fig. 5—Premier disc, mate of that shown in Fig. 4, designed to afford well-regulated surface

Marmon Idea Has Special Virtue—That there are divers ways of delivering satisfaction is shown by Fig. 10 of the Marmon, which is a leather-faced cone clutch, but, unlike other forms of cone clutches, the leather is pressed into engagement by means of spiral springs, which are placed in sockets around the periphery, and by means of a mushroom which engages above and interprets the spring pressure, the leather is maintained in good relation with the friction surfaces at all times. This type of clutch has proven of the greatest value, and is a fine illustration of the extent to which engineers may follow their own bent if only they confine themselves to good work, maintaining friendly relation with the laws which control.

Regal 30 Represents Correct Assembly—In the Regal 30, as offered in Fig. 11, the cone clutch is pressed into engagement against a truncated cone of conventional angle, and the leather face is pressed into intimate relation by flat springs. The female member of the clutch is integral with the flywheel, and a universal joint is placed just back of the clutch sleeve, with a bearing intervening between it and the universal joint which serves as the termination of the torsion tube, which is concentric with the propeller shaft. The bearing, which is a Hyatt, is made of special nickel steel, and the work which the torsion tube lends at this junction is taken care of, so that it is not transmitted to the clutching members.

Connecting Rods Are of Special Steel—I-section drop forgings of a special grade of steel is used for connecting rods, it being the idea to limit the weight of the reciprocating parts to the utmost, and Fig. 12, of a Premier, is a good example of present practice. In this work, owing to the kinetic requirement, the material must be with well regulated carbon and metalloids; when the forgings are made they are also annealed, and a certain rigidity is catered to in the process. This connecting rod is for the 40-horsepower motor, and since all dimensions are given it will not be necessary to prolong discussion.

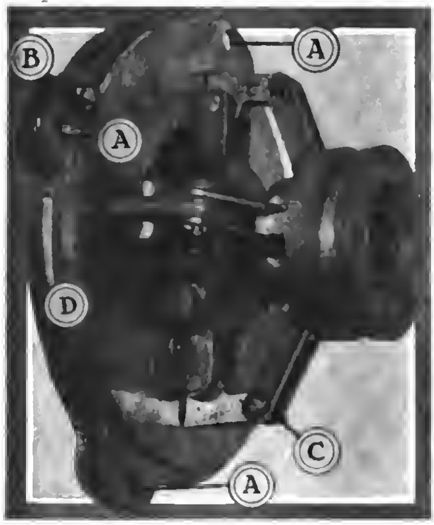

Fig. 7—Jackson plate clutch, engages through a toggle motion, with soft but positive action and easy adjustment

Still another connecting rod is that of the Moon, as presented in Fig. 13, for use in the Model 30, in which it will be observed that the metal is nicely distributed. The drop forging is of a selected grade of steel, annealed and otherwise rendered fit.

Cylinders Show Much Improvement—Fig. 14, of a Premier, is given complete, to indicate the extent to which drawings have to be made in order to assure good and uniform pattern, as well as in machining. In this example there is evidence of certain refinement in that the walls are of great uniformity, the cylinders being cast in pairs, and at A in the section it will be observed that the oilway is drilled in two diagonal directions, in order that the oil will reach the piston pin when the piston is at the bottom dwell point, and in order to be able to accomplish this, considering twins, it is necessary to drill in in the manner as shown. This is a fine example of care in design and construction as it obtains in the better cars of the year.

Referring to Fig. 15, of a Moon Model 30, which is the new Moon example, it will be observed that it represents a T-type of cylinder of extremely good design, and is a little more noteworthy in this case, due to the former practice of the Moon, which was to build with valves in the head. It is the claim of the Moon Motor Car Company that for the smaller car, as here represented, there is a little, by way of flexibility, to be taken advantage of in thus designing.

Fig. 16, which is a Rambler, differs materially from some of the other designs, it being of the individual cylinder genera, with well-regulated thicknesses of walls, special material as put out in

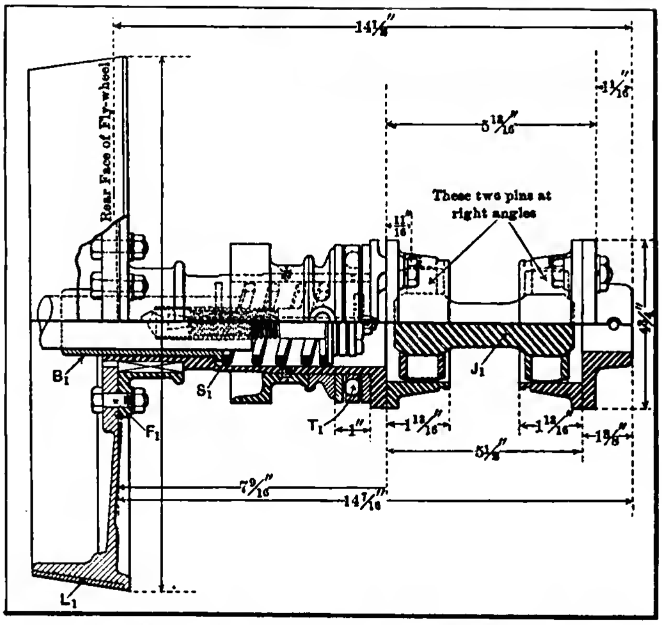

Fig. 8—National cone type of clutch with leather facing and flat springs to press leather out when square spring is free

the Rambler foundry, and so shaped as respects the frame-swept surfaces that cooling is efficient and easily accomplished.

In the smaller motors, as used in many cars of the year, cylinders are cast "en bloc," considering four-cylinder motors, and insofar as practice has shown they are very efficient indeed, rather going to indicate that practice in the foundry is up to a high standard.

Crankshafts Have Plain Bearings Mostly—Ball-bearing crankshafts, in spite of their good qualities, have made but little headway, although abroad there is some evidence of a revival of this excellent form. For the cars as they are to be seen at the Palace the best practice may be reflected by presenting a few of them, among which the Premier as presented in Fig. 17 will be mentioned, and, as will be observed, the flywheel is flanged on, bearings are liberal, and the proportions of the throws are in good keeping with the best requirements.

The National, as used in the motor of the Model 40, has all dimensions, given in Fig. 18, in which there is evidence of reserve strength, and the fine Italian hand of the designer left indelible finger prints. The throws are designed for strength, and considering the power of this motor at higher speeds, the section of the main bearings is made ample for the purpose; this motor speeds up to nearly two thousand revolutions per minute within the "stability" range of performance, and the crankshaft is balanced on this account.

In the little Brush runabout, while the car is sold at a very low price it has been possible to employ a crankshaft of splendid design, as shown in Fig. 19, and the material, which is a selected grade of crankshaft steel, is quite up to the standard set for the higher priced cars. This crankshaft is provided with means for attaching balancing arms,

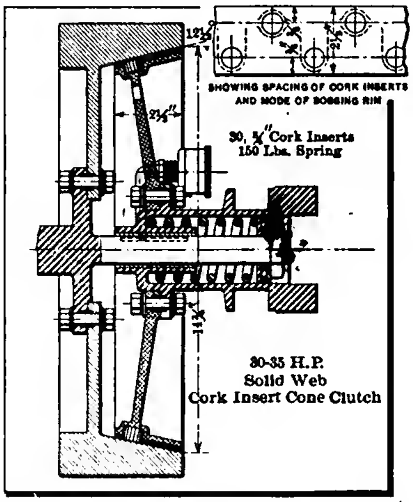

Fig. 9—"Cork Insert" clutch, of the cone type, made by General Manufacturing Company for many car makers

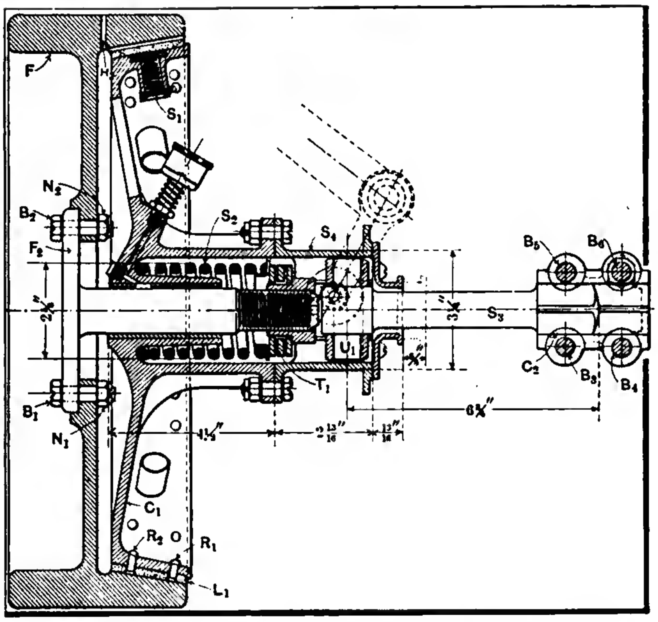

Fig. 10—Marmon clutch with leather facing and spiral springs placed to press leather into good engagement.

which are used in conjunction with a secondary balancing member consisting of a weighted gear, meshing with a pinion on the crankshaft, much as described in THE AUTOMOBILE, issue of October 14, 1909.

Transmission Gears Spell Finality—Selective types of transmission gears are used to the greatest possible extent, it being the case that the planetary types are limited to a very few of the smaller cars, barring one or two special examples. In the sliding gear systems, while there are some with four forward speeds and reverse, even so, three forward speeds prevail in the majority of cases. In one instance, the Hupmobile, a two (forward) speed sliding gear is used, the reverse being included, of course.

Fig. 20, of a Premier, will serve as a good example, it being for three speeds, selective, with reverse, and annular type of ball bearings are used throughout. The shafts and the gears, are made of a superior grade of alloy steel, are also relatively short, of liberal cross-section, hence free from any tendency to deflect under the load. The annular ball bearings are properly placed, the inner raceway being locked on, besides being a "sucking fit." The racks by means of which the sliding gears are shifted are of good diameter, reciprocate in long bearings, and the fork-arms are shaped for the work to be imposed upon them.

Unit Type of Transmission Interesting—In the American Simplex, made at Mishewaka, Ind., the unit type of axle and transmission is elaborately worked out with the lay shaft on the side, and the section shown in Fig. 21 is in the vertical plane, showing the location of the reverse pinion, laying in a depression in the bottom of the case in the same plane as the main shaft. This pinion rolls on an annular ball bearing, and the spindle is prevented from rotating by a through bolt at one end. Fig. 22 is the other view of this system, in which the relation of the lay shaft is clearly depicted and annular type ball bearings show at all points. This view also presents the jackshaft, one wheel, and shows the method of joining the wheel to the shaft, using taper fits and a hubnut of competence. The bevel pinion rotates on a pair of annular type ball bearings, thus taking the load in such a way as to prevent bending of the spindle. The differential gears are of the bevel type, and the housing rolls on ball bearings too. The gear is of the three speed and reverse, selective type, and while the whole looks a little heavy, yet even so, experience has shown that the weight is well distributed, the road performance being thoroughly good in every way. The materials used in the gears, shafts and other parts are alloy steel, excepting the case, which is of aluminum.

Marmon Presents Evidences of Refinement—As shown in Fig. 23, the unit system prevails. The transmission gear is of the selective type, with three forward speeds and reverse, and direct drive on high speed is brought about by sliding the internal gear G1 into mesh with the teeth of the pinion G2. Hill-climbing gear is let in by meshing the external teeth of gear G1 with the teeth of G3, when the gear ratio is unity, due to the fact that both gears have the same number of teeth; this leaves the bevel drive as the only means of gear reduction in intermediate speed, which reduction is that due to 53 teeth in the bevel gear and 16 teeth on the mating pinion, and 53/16 = 3.31. Low gear, used for accelerating, is let in by meshing G4 with G5, and the reverse requires that G6 and G7 engage with G4.

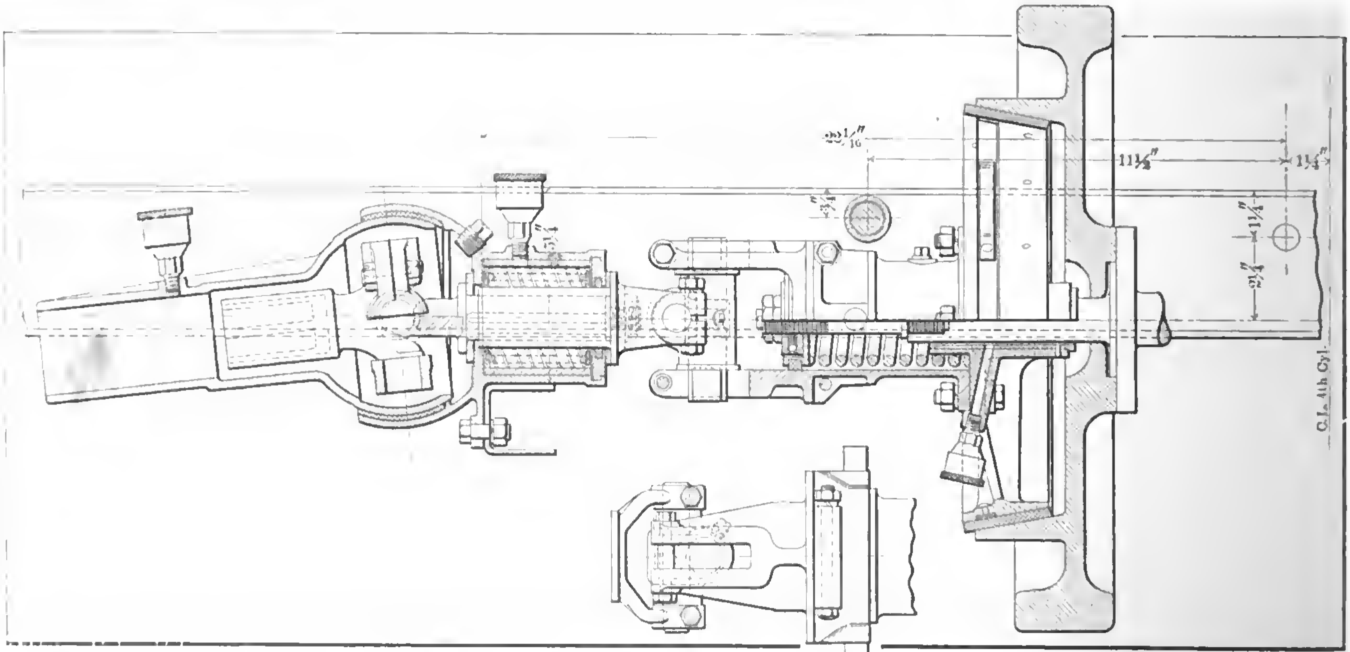

Fig. 11—Regal clutch, universal joints, torsion tube termination, and Hyatt roller bearing to resist load

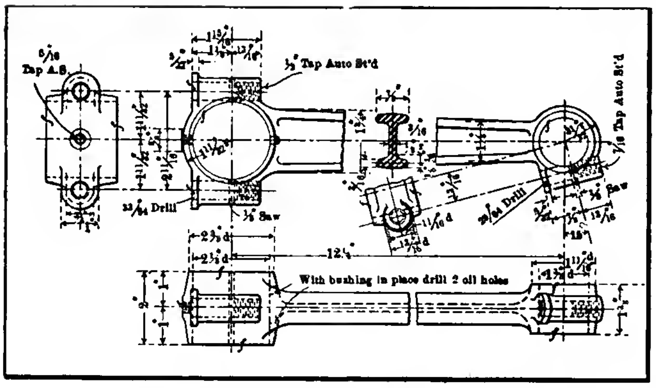

Fig. 12—Premier connecting rod, die forged, of steel, and designed for strength and low secondary moments

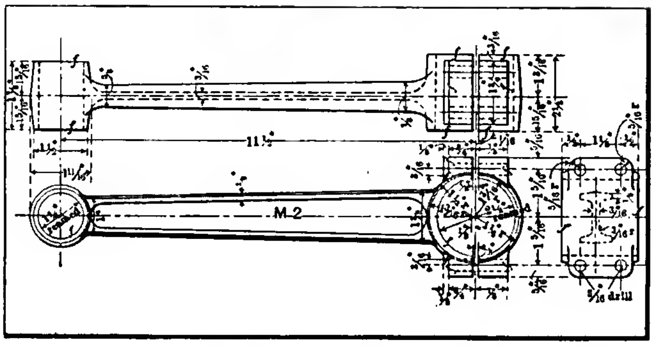

Fig. 13—Moon connecting rod, die forged, of steel, rendered light, yet strong, to eliminate inertia

The bevel drive, involving B1 and B2, with the latter flanged to the differential housing by bolts B3, B4, etc., is held in rigid relation by the large diameter shaft S1 and the large annular ball bearing B3, which is a sucking fit, and presses against the shoulder S2, is held on by pressure of the bevel pinion B1, and the end of the shaft is threaded, T1, so that the nut N1 is screwed up against the washer W1, locking the whole system in place. The pinion is prevented from turning by a key, K1, and the nut N1 is locked on by means of a wire in a groove, L1.

The lay shaft S2 is of large diameter, relatively short, hence rigid in the extreme. The gears are keyed on at K2 and K3, are of hardened special steel and of a shape to resist deformation in the process. The prime shaft S3 is a square, and the sliding gears are, like the fixed gears, hardened and of a shape to stay put. At the telescoping joint the gear G2 serves as a sleeve, and annular ball bearings B4 and B5 carry the load. Dirt is excluded by means of the housing H1, which engages the torsion tube T2, which is in concentric relation with the propeller shaft P1, and encloses it completely.

Novelty and the Rear Axle Are Companions—In Fig. 24 the jack shaft S1 is flanged at its end F1, and a supplementary flange, F2, bolted to the flange of the jack shaft, is faced off and fits against a face on the hub member, H1, of the rear wheel on each side of the car. The hub H1 is bored out to take a single annular ball bearing, B1, and this bearing, while it does all the work, is dead on the center line of the wheel, so that it is in a position to assume all the responsibility. The ball bearing is a sucking fit on the reduced diameter of the bronze sleeve S2, and this sleeve fits over the drawn steel tube T1, which is concentric with the jack shaft.

The ball bearing is held securely in place in the most approved manner by means of a locked threaded shell, S3, and the jack shaft, which is of the semi-floating type, is prevented from floating off by the interference of the petticoat P1 of the hub member H1, acting in conjunction with the flanges F1 and F2, they, in turn, being secured in place by means of the hub flange bolts B1, B2, etc., and the rivets R1, R2, etc. The hub cap C1 fits over the flange F2, and is held in place by cap nuts N1, N2, N3, etc., and the appearance of the wheel is somewhat unusual, due to the elimination of the conventional hub.

The brake drum D1 is fastened to the spokes S3, S4, etc., and the drum, while it is of unusual diameter, is also very wide, there being room, side by side, for the two sets of brake shoes S5 and S6. The shoes are faced with asbestos fabric, F3 and F4, which is heatproof and possesses a high coefficient of friction. The shoes are prevented from dragging by the springs S7 and S8, and when it is desired to apply the brakes it requires but a torsional effort on the brakeshaft S9 or the concentric tube T2 for the other set of brakes; this torsion, applied to either set

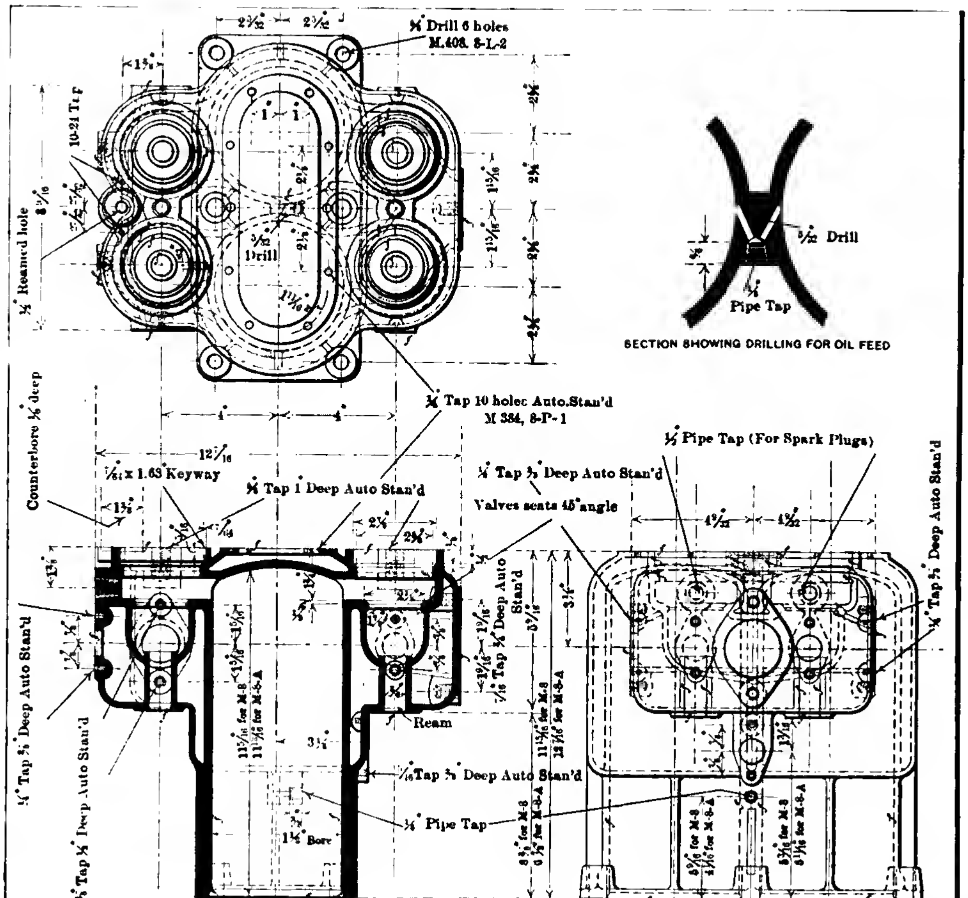

Fig. 14—Premier cylinder design, showing completeness of undertaking, uniform walls and efficiency of scheme

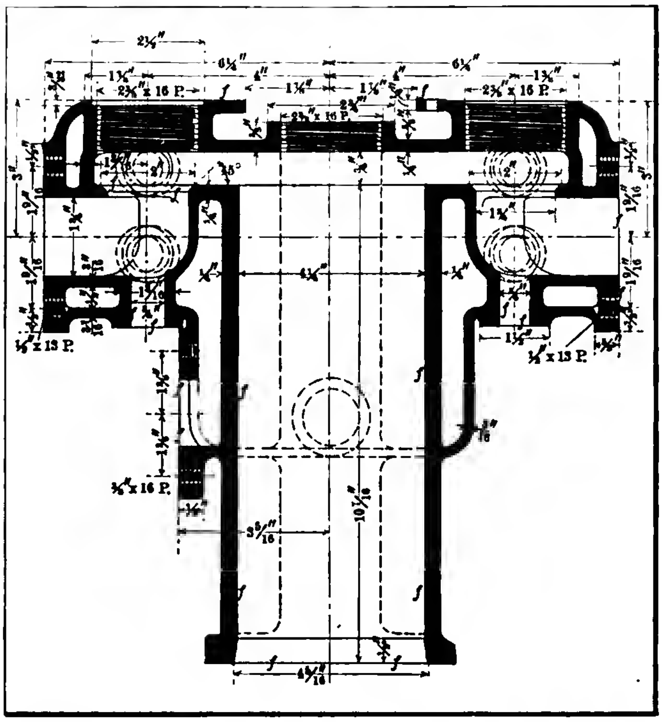

Fig. 15—T-type of Moon cylinder, which is the latest idea in Moon practice, depicting excellence in design

of members, will actuate the respective cams C2 or C3, expanding the bands and applying the necessary pressure to arrest the motion of the car. The brakes are powerful, and, all told, the area of contact of brake shoes is close to 352 square inches, and while the area of surface is not the main factor when effectiveness of brakes is to be determined, it is true, nevertheless, that the life of the brakes will depend upon this area of shoe contact.

Compactness is a Desirable Feature—The Regal, Fig. 25, is a type of unit transmission which for compactness and utility represents an advance, and the nickel-steel Hyatt roller bearings have the virtue of serving well the intended purpose, besides accentuating the compactness noted. This transmission is of the three-speed selective, with reverse, and, being carried by the rear axle below the spring suspension, takes up but little room, which counts as an advantage, as was shown by the Regal "Plugger" on its trip across the continent.

Live Rear Axles Much Improved—Taking the Premier as a type, the tube is of substantial design, but light, flaring out to a spherical bulb at the middle, as in Fig. 26. Timken roller bearings, R1, are placed on each side of the differential housing D1, which supports the differential member in the tube just at the enlargement, and the differential shafts are provided with liberal bearings, B1, at a point just before the square S1 engages the differential pinions. The most interesting point, perhaps, is in the detail of the propeller shaft just as it enters the housing, showing bearings B2 and B3, of the annular type, taking the load imposed by the bevel pinion and the bearing B2, supported by the dished member D2, which is made of steel.

Out at the wheel, Fig. 26, the brake drum D3, which is of large diameter with a brake-shoe area (total) of over five hundred square inches, which drum supplants the hub flange, being bolted directly to the wood, this being possible since the drum is integral with the hub. The driving jaws J1 are inside and the ball bearing B4 is just where it is in a position to take the load due to the jaw connection. The hub H1 of the wheel is fitted at A1 and A2, and a nut, N1, inside of the hub cap, keeps the wheel on the jackshaft. This axle, in view of the good service it has rendered, may be looked upon as representing permanence and one of the earmarks of automobile engineering.

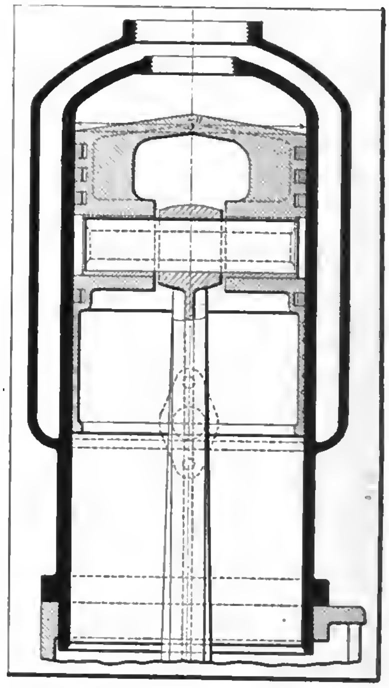

Fig. 16—Rambler cylinder, in section, cast individual, of great uniformity, and conforming to best requirements

Automobile Wheels Are Stout and True—As an illustration of present practice in wheelmaking, Fig. 27, of an American Simplex, is here offered, it being the case that the woodwork is especially well fashioned and the hub, which is of a good grade of steel, has excellent flanges for the purpose. In all respects the wheel is so clearly shown that further space will not be taken in discussing the details.

Lubrication Makes for Long Life—Noiselessness, which is the cry of the autoist, and which causes more annoyance this year to builders of cars than any other one point, will not for long re-

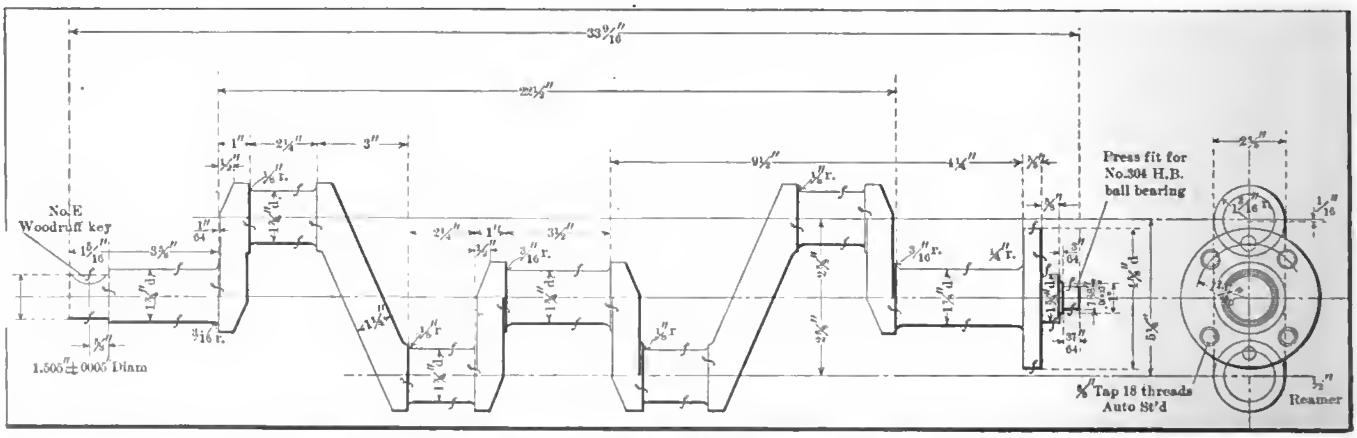

Fig. 17—Premier crankshaft, with flange for flywheel, using fine material and shaped for long life in rigorous service

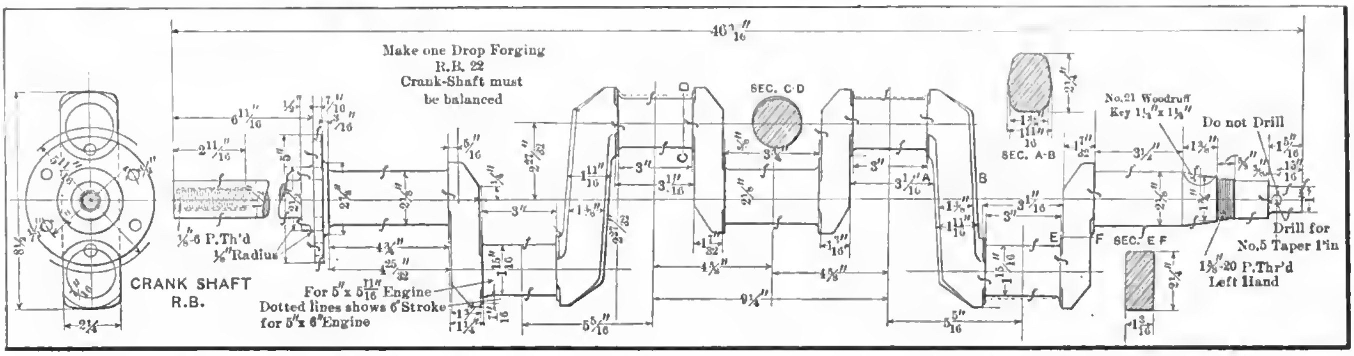

Fig. 18—National crankshaft, made of best crankshaft steel, with stout throws and perfectly balanced for high speed

main a fair claim for a car, no matter how well it is made, unless lubrication is absolutely effective. Grease cups serve a very important purpose in the cars of the year, they being placed at every point of vantage around the chassis where profuse lubrication by other means cannot be induced.

Fig. 28, representing an end bearing of a Rambler motor, shows how carefully details are cared for when reference is had to lubrication in which the oil is returned to the crankcase through the way W1 after it has served its purpose, which is to lubricate the bearing and keep the silt of the road out.

Fig. 29, of a Moon Model 45, is representative of the best practice, in which the oil is fed through oilways O1 in the crankshaft through spaces enclosed by plates B1, which rotate with the crankshaft, and the oil is thrown out to the right point by centrifugal force. The oil enters the spaces from the bearings, and the original feed is from a pump which brings the oil to the openings, one of which is shown at O2.

Regal Lubrication Is Positive—While the positive system of lubrication is used, it will be worth while to note that in this motor the oil level is maintained by means of an overflow system to a "sump" which shows in the bottom half of the crankcase, to the right. When the oil enters this space it is lifted by a gear pump of excess capacity, passes up through passageways in the case, and is shot out against the bearings to be lubricated, which bearings are suitably provided with channels for the purpose. The result is, the lubrication is profuse. Since it is important to know how much lubricating oil there may be in a system, the motor is provided with a tell-tale so located that it may be readily seen, and is actuated by means of a float in the oil well, but it is so arranged that the glass will not coat over and hide the readings. The float is of cork, and operates much the same as the float of a carbureter. This is fixed at the lower end of a vertical rod, upon the upper extremity of which is attached the indicating disc. The latter thus moves up and down, with the float which marks the oil level, and registers the same on the gauge glass, the same being visible to the driver from the exterior.

How National Lubrication Is Coped With—By referring to Fig. 30, which is a section of the crankcase, longitudinal at A and cross-sectioned at B, the lubricating oil is held in a basin, B1, which in section looks as in B2. In the same sectional view the filter F1 is placed, and the arrows show that the oil flows in, it being cleaned at this point. The crankcase is scooped out, or, better yet, it is contrived with a false bottom, B3, with well-holes, W1 and W2, leading into a passageway, P1, connecting the two, and at the mid-position of this passageway a third well-hole, W3, is placed, the purpose being to equalize the flow of oil, preventing it from piling up when the car is negotiating a grade, and in this way the cylinders are prevented from becoming fouled.

Referring to the cross-section B, Fig. 30 again, the oil-pump P2 is located in the bottom part, is driven by the vertical shaft S1 and Oldham coupling, O1, prevents the shaft from being cramped and allows the gear-pump entire freedom, so that the members are free in the housing.

How the Lubricating Problem Is Generally Handled—In the Paterson Model 30, which is made at Flint, Mich., is a unit power plant, with four cylinders cast in pairs, lubrication is by constant level splash, and means are afforded for the profuse lubrication of all the bearings by means of suitable oilways. The transmission, which being integral with the motor, takes all excesses of oil that may get by. The oil is held in the bottom of the crankcase, and by means of a pump excesses of oil are disposed of; at the same time the right amount is positively maintained, due to the placing of suitable dams (ribbing) in the case. A cone clutch is used.

In Mitchell cars, made by the Mitchell Motor Car Company, Racine, Wis., the oiling problem is met by using a Lavigne lubri-

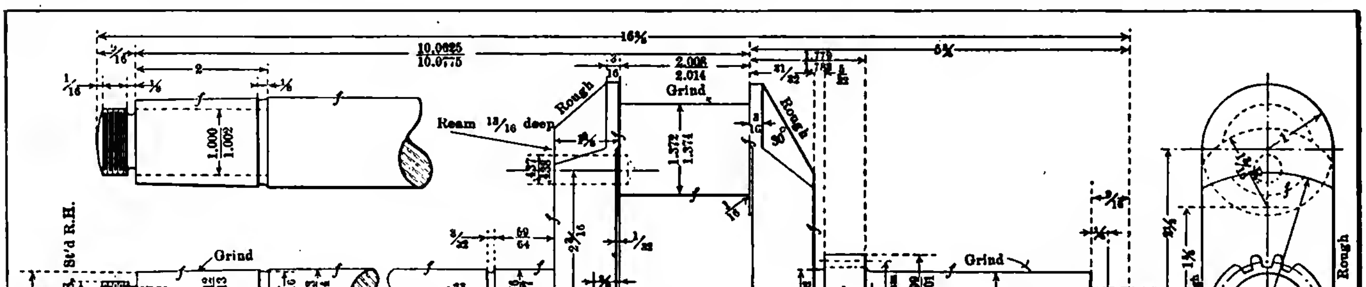

Fig. 19—Crankshaft as used in the Brush Runabout, for a single cylinder vertical motor, and balanced for high speed

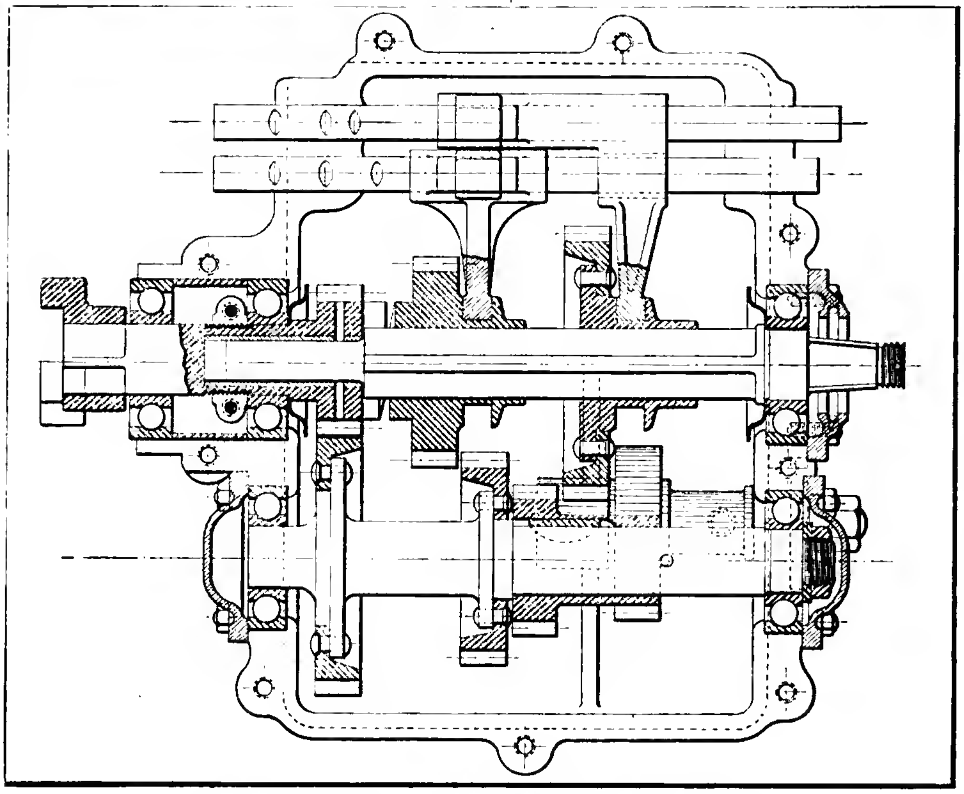

Fig. 20—Premier transmission gear, for three speeds and reverse, selective, and direct on high

cator, which, being positive, has the virtue of delivering the exact right amount of oil to the respective bearings with certainty. The oiler is located on the crankcase, at the front to the right, is belt-driven, and two of the six leads go to the cylinders, while the remaining leads connect with the end bearings of the crankshaft, clutch and crankcase. In the Mitchell there are divers mechanical features that should be given space, but in view of their novelty it is necessary to consider a time when the whole car will be taken up for the purpose of exploiting its excellent qualities.

In the Reo car, referring to the 1909 four-cylinder model, the question of lubrication is cared for in a somewhat different way; the system is self-contained, and piping is entirely done away with. This is brought about by having the plunger pump which is used down in the crankcase, it being driven from the camshaft by means of an eccentric. Lubricating oil is pumped up from the reservoir in the base to the three main bearings of the crankshaft and to the faces of the spiral cams. The plunger pump has the virtue of lifting a definite amount of oil at each stroke, and the number of strokes increase with the speed of the motor, so that lubrication increases as the requirement.

In the Chadwick, made by the Chadwick Engineering Works, Pottstown, Pa., oiling is by splash, but the force-feed oiler is direct drive, hence chances of failure are eliminated. The oil is independently delivered to the respective bearings by separate pipes, and the oil level in the crankcase is definitely maintained. The pump delivers oil to 14 points, i. e., six cylinders, four main bearings, three compartments in the crankcase, and one to the transmission gear case. In this way the condition of lubrication is definitely maintained at every point, and as a result the Chadwick is insured against undue wear, thus eliminating noise as a future prospect. In this make of cars the chains are booted, they being of the side-chain drive design, and by thus keeping out the mud accumulations which would otherwise attach to the chains they are maintained in good working order for several years.

In Stoddard-Dayton automobiles, as made by the Dayton Motor Car Company, Dayton, O., lubrication this year is attended to by utilizing a rotary pump rather than the plunger type of previous years. This is claimed to be a better plan, the idea being to copiously lubricate every bearing. Grease cups are also placed at all points, as on spring shackle bearings, and the springs for this year are 3-4 elliptic, rear, of a very well executed design, the front springs being 1-2 elliptic, which is desirable under conditions of constant loading. With Stoddard-Dayton cars a "lubricating chart" is delivered with each automobile, it being the idea to coach each owner in the art of attending to this important matter, the Stoddard-Dayton maker fully realizing the necessity of maintaining a profuse state of lubrication if noise and trouble are to be kept out; the very essential detail, however, is that oiling facilities are provided in the cars, thus putting it up to purchasers to do the rest.

Large Diameter Road Wheels Help Out—The American Traveler, made by the American Motor Car Company, Indianapolis, Ind., differs from many products, in that 40-inch road wheels are used and lubrication as a requirement is somewhat reduced on this account, insofar as road wheels are concerned. For the rest, a gear pump is employed, being connected in the engine case, with a sight feed on the dash. A container located in the crankcase holds 1 1-2 gallons of lubricating oil, and two extra gallons of lubricating oil are carried in a separate reservoir, thus assuring an adequate supply for touring, which is what the car of this subject is much used for. The liberal use of annular type ball bearings in this model, as well as in all cars of

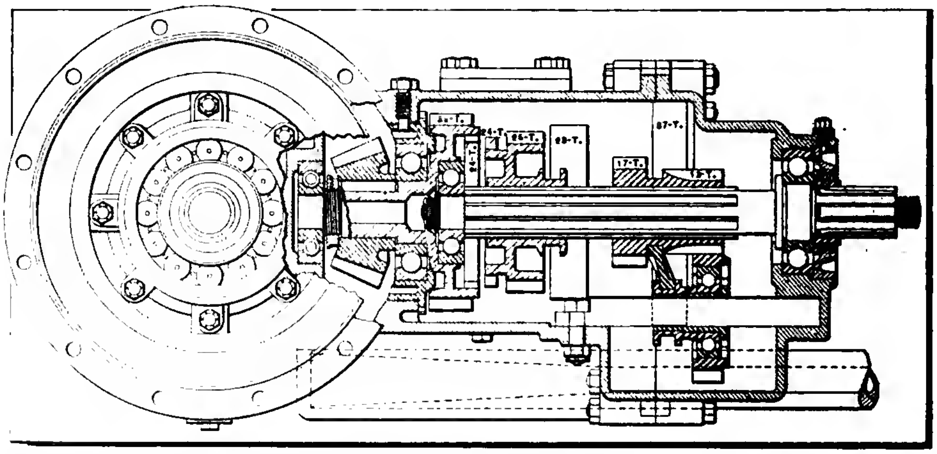

Fig. 21—American Simplex unit type of transmission, longitudinal section in the vertical plane

this company, reduces the lubricating problem to a low level, although, of course, a power plant of the proportions of that used in the Traveler requires more than the ordinary amount of lubricating equipment, which is the reason, perhaps, that the company has made such liberal provision. In this car the motor has a bore and stroke of 5 3-8 x 5 1-2 inches, respectively, and is rated at 60 horsepower, which, as ratings go, is very conservative to say the least. The transmission, which is a selective four-speed and reverse, as well as the differential, which is of the bevel type, run in oil. Power is on an increased basis, largely due to nice design features, and the ignition, which is a Bosch high-tension (dual) system, is so utilized as to afford the best results.

Success Accentuated by Bearings Used—Practice, from the point of view of bearings, excludes plain bearings from all but crankshafts, for the most part. While there is slight indication of the ability of annular types of ball bearings in crankshaft work, even so, considering service rendered by plain bearings in this zone, designers have been a little slow to depart from them.

Of the anti-friction bearings used, the main point to be made is that there is no hard-and-fast preference, it being the case that quality resides in the several types, and in selecting them it is more to the point to employ liberal sizes and having them made of good material, accurately, than to select some one generic type of bearing without bothering much about quality of material and workmanship.

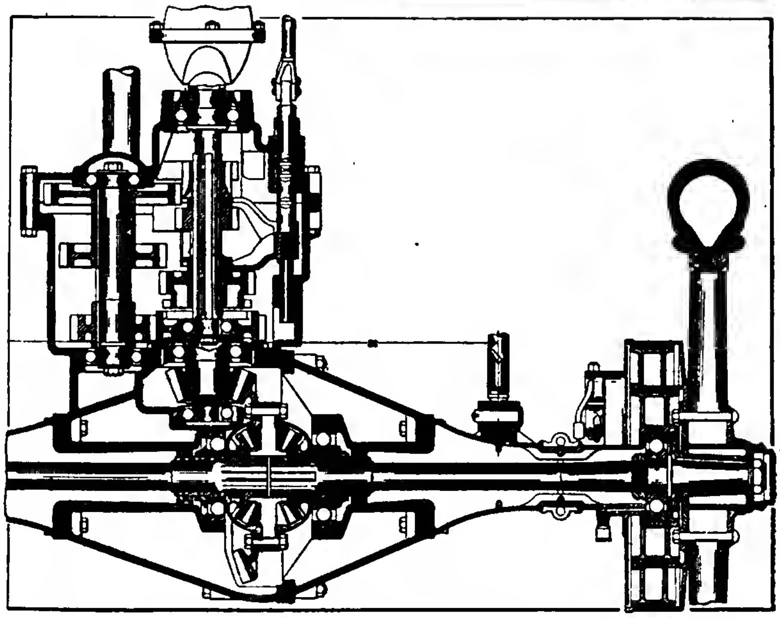

Fig. 22—American Simplex, showing unit transmission system, in section, cut through horizontal plane

The cars of the year, among the makers of the subject, are provided with:

(A) Hess-Bright (D.F.W.) annular type ball bearings;
(B) Bretz (F. & S.) annular type ball bearings;
(C) New Departure dual annular type ball bearings;
(D) R. B. F. annular type ball bearings;
(E) Standard roller bearings;
(F) Timken roller bearings;
(G) Hyatt roller bearings;
(H) Cup and cone bearings of various makes;
(I) A wide variety of thrust bearings by the several producers.

Materials Used in Ball and Roller Bearings—In plain bearings, considering the better class of work, the anti-friction members are "die cast" more often than not, and copper-tin mixtures obtain to a vast extent. In the copper-tin mixture the proportion of tin is 90 per cent.

In the annular types of ball bearings, while there is a wide variation from the point of view of materials used, even so, it is the general practice to employ far better products than those of former times, which is a good reason why failures are scarcely ever to be noted. In some of the bearings the carbon is 100 points; in other examples, 90 points. Some of them are alloyed with chromium; more are not, but in all cases it is the aim to have the metalloids very low, and crucible steel obtains to a vast extent.

In roller bearings, especially those which are cemented, special grades of cementing steel are used, in which the carbon is probably under 16 points in the initial material, and the purity of the stock is looked after with the greatest care. In this class of work, as a result of the methods of heat treatment, the shell is quite as hard as that of the hardest balls (the carbon being the same or even higher), while the core is relatively soft and kinetic properties are coaxed into the material by this method.

CHASSIS WORK IN FULL KEEPING

While the chassis frame is utilized as a platform for the machinery equipment, and serves as well for a place on which to rest the body, it is not looked upon as sufficiently stable to offer adequate rigidity, all things considered, and flexibility is imparted to the machinery units—so much, in fact, that the chassis frame is not expected to do more than serve as a bridge, as it were, in which class of work flexibility is courted.

The scheme of design, then, for automobiles, taking them as a whole, is on a basis of flexibility, which characteristic is embodied in the frame to some extent, and in the assembling of the machinery unity to the maximum possible degree. In chassis frame work there are three prime methods in vogue:

(A) Narrowed frames, without a kickup;

(B) Frames with a narrowing at the front and a kickup behind;

(C) Straight frames.

Channel sections obtain almost to the exclusion of all other shapes, and, considering the lateral tieup at several points from front to rear, the strength of the section is made a maximum in the vertical plane and minimum in the transverse plane.

In many of the cars of the day the rear suspension is 3-4 elliptic, and the frame is stopped off just back of the center line of the rear axle, unless in the examples in which the body is ex-

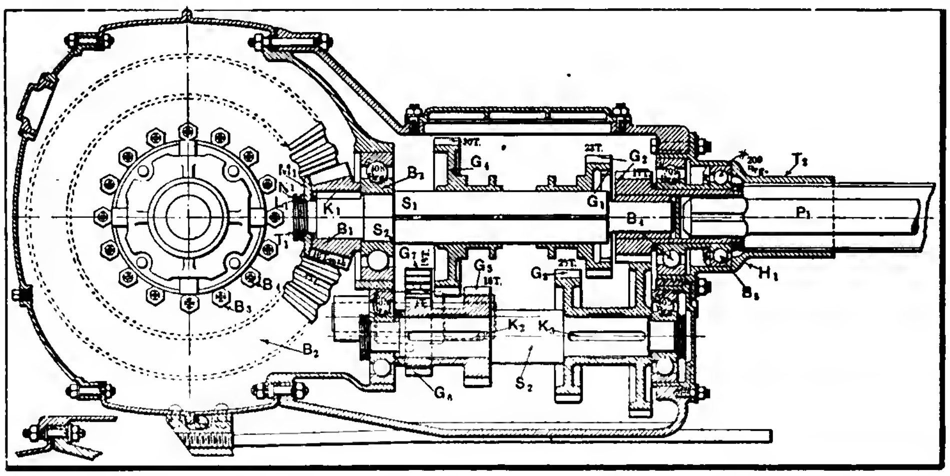

Fig. 23—Marmon unit system of transmission, with lay shaft below, and appearances of excellence of design, using fine materials

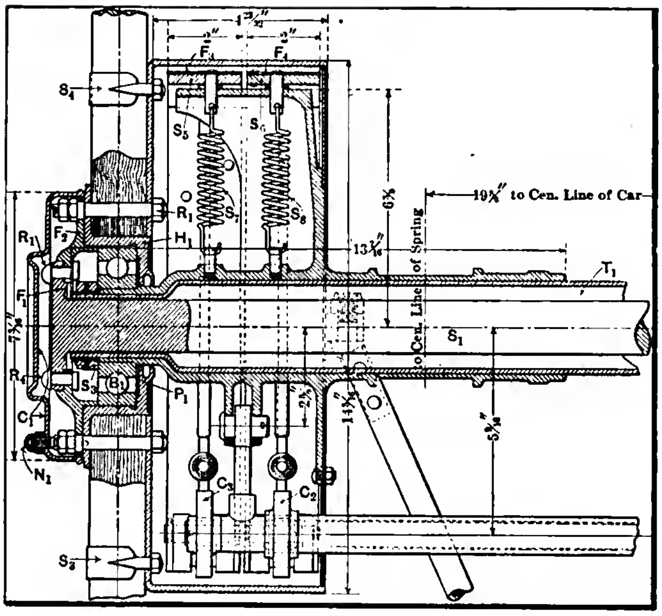

Fig. 24—Marmon live rear axle, showing brakedrum of good diameter, and wide enough to accommodate two sets of shoes

tended back a greater distance, when, of course, the frame is extended back also. The design, as found in National cars, is an excellent illustration of a kickup at the rear and 3-4 elliptic scroll springs, they being wide, with a liberal allowance of metal in the plates, without having them too thick, the result being that the cars ride well, part of which performance is, of course, due to a good length of wheelbase, and, perhaps, to the low center of gravity which is natural to frames of this character.

In the American cars with underslung frame the center of gravity is very low indeed, and having the frame below is another way of realizing all the good that comes from a kickup. The American frames are narrowed at the front to afford a liberal turning angle of the front wheels, considering the use of 40-inch tires on the road wheels.

In the Stoddard-Dayton cars the 3-4 elliptic rear springs fasten on to the rear termination of the chassis frame in such a way that the springs fall outside of the outer line of the frame and the work comes on a liberally sectioned rear lateral. Taking it on the whole, it is a neat piece of work, and one of the points well worth examining in the cars of this make.

The Premier, from the chassis frame point of view, is a fine example of stability, considering the manner of caring for lateral work, in that the web of the channel section is extended down just at the point of narrowing, and strength is added in the process to a marked extent. The shape of the Premier, taking it as a whole, is for strength, it evidently being the idea of the designer to have the frame stand up under collision conditions, and the extension at the front, for illustration, is much as a strut. In the Moon and some other frames, in order to add strength just at the point of narrowing, the flange is widened and cross members come at the place of greatest advantage.

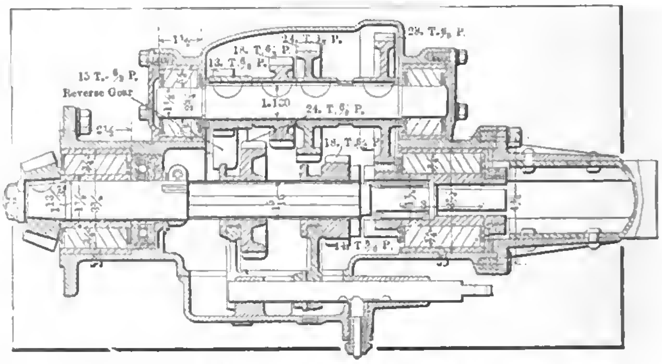

Fig. 25—Regal transmission gear, showing compactness, and Hyatt nickel steel roller bearings

The material used is also on a basis of rigidity, and in the fashioning an attempt is made to preserve the metal to the greatest extent, this being done by making the turns with the greatest possible radius.

In the Cole "thirty," which is a newcomer made at Indianapolis, the chassis frame is neat, strong, and has the virtue of being along tried-out lines. In this car, also, the shaft for the steering gear comes out above the frame, and a secure fastening out of harm's way is the product. The running boards are fastened to the frame by means of pressed steel hangers, and, taking the frame as a whole, it is an excellent piece of work, matching up with the whole car.

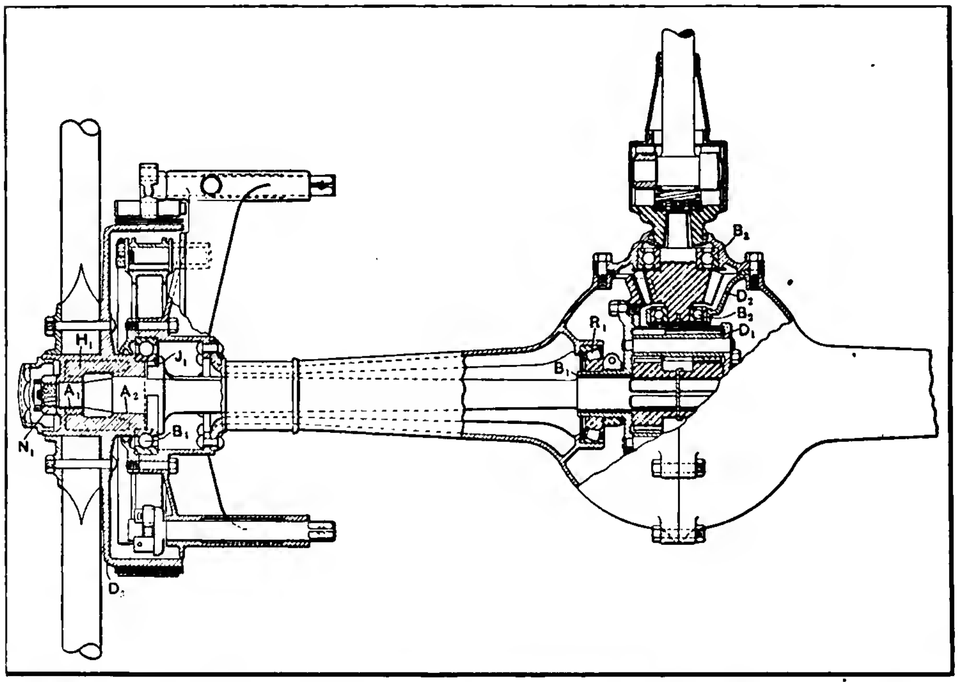

Fig. 26—Premier live rear axle, presenting tube of great strength and lightness, with brake drums of liberal area, and bearings of unusual ability throughout

Materials Used in Chassis—Nickel steel is the mainstay—it being of a special grade, suitable for work of this character, taking into account the bending process and the effect of abuse of this character on the material. On account of the toughness and strength of this steel the work is done hot, and when the frames (sidebars) are formed they are then annealed. In some instances, in order to induce quality to the maximum, the sidebars are oil-quenched and then annealed.

As a second grade of side-frame stock, boiler plate is used, the same being acid open-hearth material low in carbon and fabricated to induce the requisite qualities. Next to boiler plate, which makes a superior frame, basic steel is employed, and when it is a specification product the results are very satisfactory. This and cheaper grades of steel plate, when they go into sidebars, are handled cold and annealing is sometimes neglected, account being taken of the quality of the car in which they are to go.

In assembling chassis frames some of the builders use the hot process, in which rivets are heated, placed into the holes and then riveted over. This process is advocated by them on the ground that when the rivets cool off they will shrink, and in so doing press the members into a closer relation. The rivets are made of a special rivet stock, low in carbon, hence not readily damaged by heating. In other plants all this work is done cold, and in some of them the holes in the plates are drilled.

It is true, of course, that punching does damage the material, and drilling the holes has the virtue of leaving the same in better fettle than it will be after punching. On the other hand, a poor quality of material can scarcely be improved by any one of the detailed processes, and a reamed punched hole in good material is regarded by many builders as very satisfactory.

I-Section Axles Without Welds—In the cars of the class using live rear axles the front axles are as a rule of the I-section, and in order to eliminate failure they are drop (die) forged in one piece. The material used is approximately 20 points carbon steel, low in sulphur and phosphorus, it being a basic open-hearth steel as a rule. In occasional cases the forgings are welded at a mid-point between the perches, and in such cases the material used is of weldable quality.

In live rear axle work, as it is to be seen in the cars of the year, the perches for the springs are sleeved on and torsion is taken by the torsion member rather than through the springs, as it formerly was, to some extent at any rate. The springs, taking them as a whole, are with wider, more and thinner plates, it being true that the increased number of plates will dispose of more energy and suffer less in the process. The fastenings at the perches are much more substantial than formerly, it now being well understood that spring failures will be nearly sure to follow if the springs are not tightly clamped at the perches.

Steering Gear and Linkages Considered—While the worm and sector type of gear has many adherents, even so, it is not exclusively used, worm and nut types being in some presence

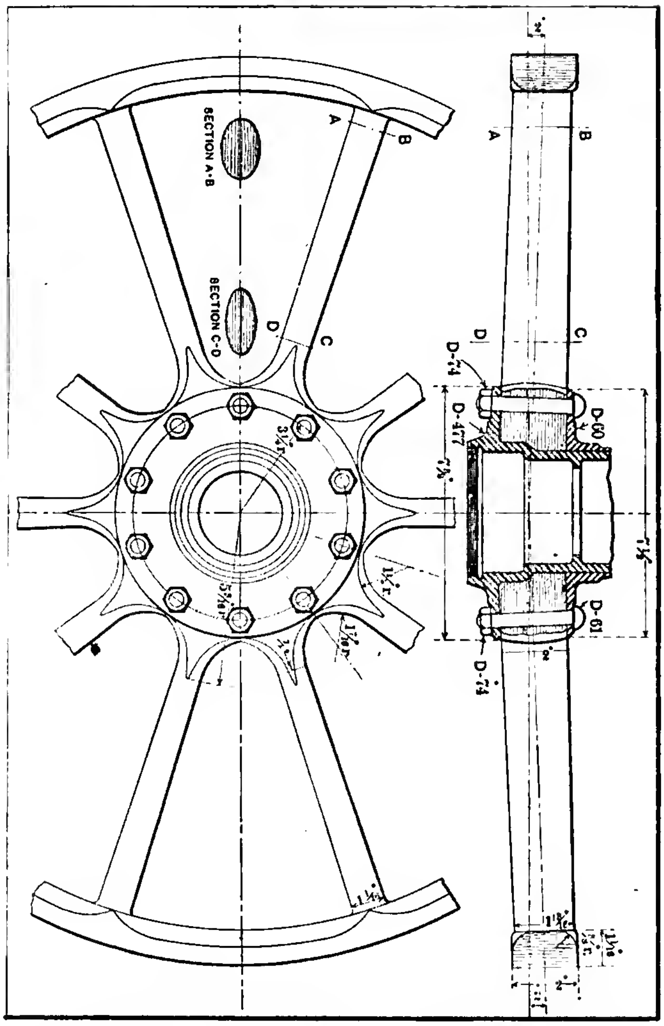

Fig. 27—Example of modern wheel, of second growth hickory, shaped for strength and ease of uniform manufacture

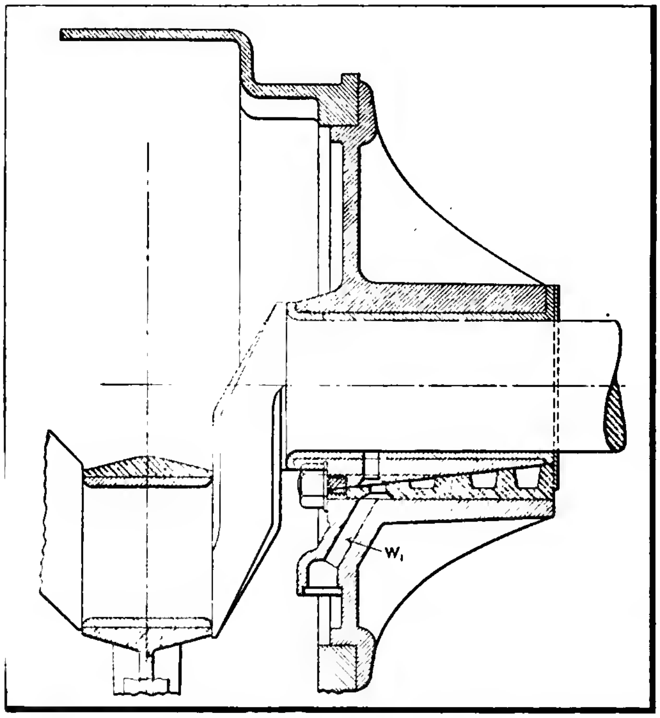

Fig. 28—Rambler, offering evidences of refinement in method of lubrication, involving the crankshaft

also, while the Gemmer type of gear holds sway in numerous examples of the cars. In nearly every car, as compared with last year, the steering wheel is of larger diameter, and where 15-inch diameter wheels was the apparent standard, 17-inch wheels now seem to obtain.

The steering wheel spider, while it is in many cases made of aluminum, is now more frequently of Parsons manganese bronze, and, as will be readily appreciated, the bronze wheels are of vast strength relatively. The materials of which worms are made are usually a good cementing stock, low enough in carbon to stand the heat treatment without being reduced to a crystalline condition, and so built up as to work well in the hobbing machine; free-cutting cementing stock, in fine, is what is wanted. After cementation, if the process is properly conducted, the hardness is that due of over 100 points of carbon in the shell, which crust, if such it may be designated, is about 1-32 inch deep.

Lost motion is avoided in the worm and sector types of gears by having the angle so that the gear is not quite reversible, and, contrary to the belief of some, complete irreversibility is a condition which should be avoided. Besides taking advantage of a favorable angle, it is the practice to provide a pair of eccentric bushings for the worm, and by means of them adjust the worm in closer relation with the sector when the occasion requires. In certain examples, in view of the way the worm and sector wears, the sector is shaped to compensate for the wear, thus making the adjustment more profitable.

Tierods and draglinks, as they obtain in most examples of cars, are most carefully made, and if they have to be crooked the method of doing the work is carefully considered. The diameters of the tubes are regulated in view of the shape, and if brazing is done the parts are pinned as well. Purchasers of acumen this year are inclined to give this matter a little attention, and it is reasonable that they should.

Body Work Has Advanced a Pace—Torpedo types of body work look a little novel; they represent something by way of utility, keeping out the cold, reducing wind resistance, and are probably with us to stay, for a time at least. With the lengthened wheelbase, which is a characteristic of the year, there is more room for body innovations, and the torpedo type is the real innovation. The tendency is for more foot room in front, it being the practice now to allow about 26 inches from the panel of the front seat to the back line of the dash; last year this distance was about 24 inches, but in many cases it was less—23 inches perhaps.

While aluminum is being used to some extent in the higher priced body work, the fact remains that sheet steel and products using sheet steel as a foundation are being used to a great extent. The woodwork is on a substantial basis, and the framing is so ironed, as a rule, that body work may be regarded as on a most stable basis.

Upholstery, despite the use of some leather of a rather inferior grade, is as a rule on a fitting basis. Hand-buffed leather is much used, even in cars of quite low prices, and the stuffing in many of the examples is No. 1 hair. Machine methods of doing upholstery are now so well advanced that quality within allowable cost is a reasonable expectation. It is this advance in method, perhaps, that is at the bottom of the rather good quality, taking it as a whole, which is to be noticed.

Water Cooling by Different Methods—Of the cars with water-cooled motors, while most of them circulate the water by positive means, some employ the thermo-syphon system, notably Regal and Ford, and in the Regal, for illustration, the method of cooling is quite different from that in vogue in general when reference is had to thermo-syphon systems. In this system the water enters the radiator pocket about 2-3 up from the bottom. The water is then deflected up, or down, depending upon the offering resistance to the flow in either direction. All the water that passes up is cooled in the process, and it then descends, through separate tubes, and when it arrives at the bottom, where it mixes with the water that descends directly, it is substantially of the same temperature as the water which directly descends. In this system, as it is understood, steam, if any forms over the domes of the cylinders, is used to force the water up, and the steam is condensed before it arrives at the top of the radiator, thus preventing steam from spouting out of the top of the radiator, or through the overflow. The radiator maintains a very efficient temperature at all times, and the size of the same, despite the application of principle of the thermo-syphon, so called, is very well within the limits for other types of radiators. This type of radiator as referred to is made for the Regal by the McCord Manufacturing Company, of Detroit.

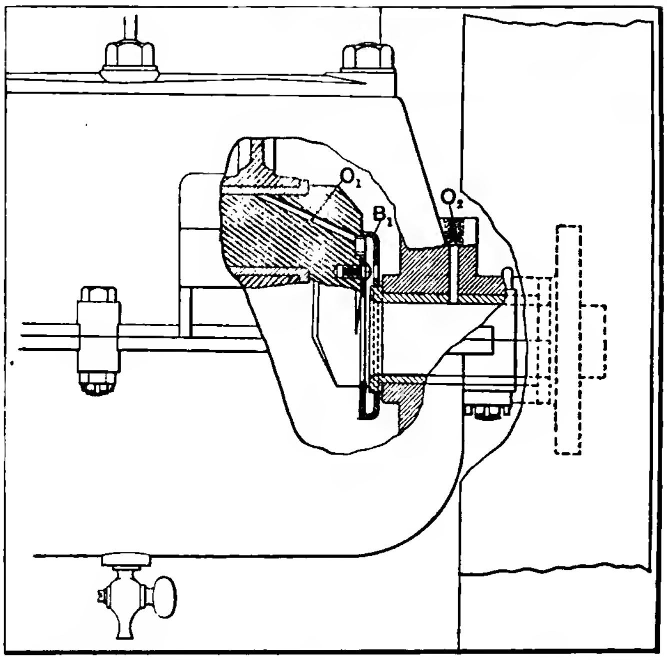

Fig. 29—Moon, presenting a detail in the method of lubricating the crankshaft, indicating ingenuity

In the commercial section, the Grabowsky power wagon, as it will be shown, will also have a radiator in which the water enters at a point below the top, but in this radiator the space above the water level is filled with steam, and the temperature being higher at this level, the quantity of heat which will be disposed of, will be greater, so that the radiator has a higher inherent ability; this type of radiator does very fine work, and it may be regarded as a type which the future should see more of.

In water circulating, centrifugal pumps are very much to the fore, it being the case that they deliver the required volume of water, and last for a long time, there being no surfaces that are prone to wear; moreover, these pumps deliver water whether they are well fitting or not. Centrifugal pumps, in view of their noiselessness, are, as a rule preferred, and, in the examples of gear pumps to be seen, they are so made that noise is practically eliminated; they must, however, be well made and of good design, to come within the class designated as noiseless.

Air-Cooled Motors in Good Presence—It would seem as if the air-cooled examples are just about holding their own, there being no desertions of moment, and the newcomers are mostly among the high-wheeled rings. Principles, as they are apparently carried out, are about on a par with former practices, referring to examples at the Palace.

Contests of Value to the Automobile Industry

By R. O. Smith, Chairman, A. M. C. M. A.

ENDURANCE contests furnish valuable information to the motor car builder and guide posts to the purchasers in choosing between cars.

If we reflect and note how little was known of the automobile, even by the makers, less than ten years since, and consider the small number of cars then in use, one would naturally conclude that it would not be reasonable to suppose that the average buyer, and particularly one contemplating his first purchase, is well equipped with the knowledge to judge the value, actual and relative, of the various cars found on the market. The public have a right to know and demand the proof of the worth of a car, but the great question is, the basis for establishing the proof. The conscientious manufacturer undoubtedly tries out and proves the worth of an idea before incorporating it into the product, and if this is true with the several individual items entering into the construction of a motor car, why would it not be reasonable to subject the entire car to conditions which would try and prove out and determine the worth of the car as a whole.

Automobiles can no longer be classed as a luxury or a fad. The purchasers are seeking value, and are interested in the ability of a car to perform properly, and its dependability. Undoubtedly some cars are better than others. Some cars of a given class or price are better than other cars of the same class or price, but the value is not altogether indicated or determined by the appearance of the car. What is in it; what constitutes the vital parts; how every part works with the other—are the bases for determining the results to be obtained from the car as whole, and the public should feel interested and have a right to know the results which can be expected of a finished car.

One or more unsatisfactory features, coupled with few or many excellent features, would make a satisfactory car impossible. Undoubtedly a perplexing question to the buyer of a car, where so much is at stake, is how to know whether or not he is getting his money's worth, and a car such as he has a right to expect.

Looking at the situation broadly, the purchasing of a motor car is in line with the buying of any other article. The average buyer of a steam engine to be installed in a power plant is probably not as a rule well posted on the relative merits of the engines such as are offered to the market, and certainly not if a decision is supposed to depend upon his personal ability to judge the engine by its appearance and several mechanical features, as they appeal to him. In such cases a decision is not arrived at without an investigation of the way the various makes perform in service, and no doubt comparisons are drawn to determine the relative worth of the various makes under consideration.

This same information concerning a motor car can be obtained. All motor cars of standing have histories which reveal the strong and weak points and what the car can be depended upon to do. This information as it comes from individual owners is valuable, but conditions prevail in the motoring world which make possible even more accurate comparisons.

Follow the contests which have been run under rigid rules and strict supervision and the history of the various cars entered, and the results carry information which can be relied upon. Not only have these contests become more rigid as cars have developed and we have made advances in the art, but added to the ordinary rules governing the road performance has been that of an inspection at the finish, showing in detail what it has cost the car to cover the course, or the effect the hardships have had upon it. Such information should be invaluable to the buyer. There is no given standard by which a motor car can be measured, but the comparative showing tells the comparative worth. From year to year we have profited by our experience in contests in this country, and each year have made them a little more rigid than the year previous.

A still better guide would be furnished the buyer, and the information would be more accurate, were it possible to have all contests of a kind carried on under like rules, with a committee selected to govern the various contests, insuring like interpretation of the rules, and awards be made only after full consideration of all the entrants guided by the rules under which the contests was started and run. This would not only give the public the opportunity of judging the cars in each contest, but the various cars in the various contests. These results should be a telling criterion and of value, not only to the purchaser, but quite as much to the manufacturer who is earnestly endeavoring to produce the best car possible. They have the effect of demonstrating to each entrant if any competing car in the contest is better, and of showing to the world the best car.

Strenuous contests tell a story which sould carry weight, as constantly keeping at it is what shows up the weaknesses.

Contests can be classified under three heads: Speed, hill-climb and reliability.

Speed contests are fascinating and instructive along certain lines. They may show the ability of the designer to produce a fast car, but this is sometimes done at the expense of durability. The history of the past shows that racing cars have frequently differed even in the fundamentals from the stock product of the same make. In designing, speed can be taken into account as the main object and the results may be at the expense of long life and reliability. It is not always the snappy and fast motor which goes farthest. In speed contests, cars are as a rule entered with a view of covering the course in the shortest time, irrespective of cost, either as relates to the whole, or damage in the way of wear and tear, the question of the car at the finish in such events being of secondary consideration, if considered at all.

By following any of the large events it will be noted the amount of work in instances which is done on a racing car to keep it going, and yet, if it crosses the tape first, it is heralded a winner, though other cars may have suffered less on account of the strain and hardship, and be capable of going much further than the winning car. A most appropriate example is furnished by one important race this season where a certain car finished first and was pronounced the winner when it was known that, due to certain parts going out of commission, the car finished on three cylinders.

Reliability is what counts in every-day service of motor cars, and most cars are capable of attaining a speed greater than the average driver can pilot a car with reasonable safety.

Hill climbs can be viewed in much the same way, since, as with a race, the conditions are usually abnormal and the temptation to build special for the particular test is usually more than the maker can resist.

Notwithstanding the fact that these two classes of events have their value, the third class, known as reliability contest, will no doubt generally be accepted as the most reliable character of events, where results as a criterion are desired, there being no object in building special were it permitted, provided the maker is trying to produce the best possible car regularly. These contests are characterized by touring conditions and tell a truth worth knowing.

There is probably no better way for one contemplating the purchase of a motor car to be assured a basis of judging cars than by looking up their records. The showing made in one of our large annual contests during the past year has astonished the world, including those who participated in the event. The Glidden tour covered a distance of almost 2,700 miles and the schedule required an average of at least a mile every three minutes on the road from Detroit to Kansas City, by way of Minneapolis and Denver, irrespective of road or weather conditions. An observer was appointed by each entrant, these observers riding on other cars, and changing every day. This avoided a possibility of violating the rules without penalty, the contestants not being allowed to use any new material, to make any repairs, to adjust so much as a bolt or screw, with the exception of brakes, oilers and ignition without penalty, and witht ignition, no exchange, replacement or repair of parts were permissible. Notwithstanding these strenuous conditions several cars finished with perfect road scores at Kansas City.

It is a true saying that motor cars, like men, have a record and a history, which tell what they are and what they have done and furnishes a most reasonable basis for deciding what they can be depended upon to do.

ADVANTAGES OF INCREASING THE WHEEL SIZES

BY CHARLES E. DURYEA, Technical Expert, A. M. C. M. A.

THAT large wheels roll more easily than small ones everybody seems to know, but it has only been a few years since that same everybody seemed to think that no real automobile could be equipped with other than small wheels. To try the self-propelled vehicle with wheels of the size in common use on horse vehicles, was to mark oneself as utterly out of fashion and was equivalent to proclaiming one's origin in the country districts.

Suppositions are often wrong and none more wrong than this. Our country cousins are just as anxious to be up-to-date as our city ones can be and they certainly equal, if they do not exceed, the city dwellers in their desire to have the latest. On this account the small-wheeled auto has found its way to every portion of the country, and wherever it has gone it has proclaimed the same truth that small wheels do not roll over obstacles so easily as large ones. The rocky country road or the cobblestone city street alike teach this lesson, and if there is any difference in the requirements with the respect for wheel sizes, it is the average city with its irregular cobblestone street which needs the large wheels, rather than the less used and therefore less worn-out country road.

As a result of learning these facts, standard automobiles have each year been increasing their wheel sizes until to-day we see vehicles like the American Roadster and the American Traveller with 40-inch wheels all around, and these large wheels equipped with four-inch tires, a size that but a few short years ago was looked upon as foolish. On the Austin 60 we find 37-inch wheels front and rear, and five inch tires. Of the autos to be shown at the Grand Central Palace show, by far the greater number of the higher priced vehicles will be equipped with 36-inch wheels, and four, four and one-half and five-inch tires. In the Chadwick we see 36 by 4 fronts, and 37 by 5 rears.

To make more clear the comparison, right alongside of these conventional autos do we find the Holsman motor buggy recognized for years as the leading maker of this type, with 42-inch front and 44-inch rear wheels, and the McIntyre with 34-inch wheels all around, with 1 3-4 solid tires. The Duryea buggyaut is equipped with 38-inch front and 44-inch rears, so that from these examples it will be seen that the motor buggy and the conventional auto are now very close together in the matter of wheel sizes, and that wheel diameter is no longer a mark by which one can say that the vehicle was built for city or country.

On the contrary, busy business men in the cities are recognizing the advantage of large wheels and are demanding same whether fitted with pneumatics or with solid tires, that they may roll smoothly and with less damage to the mechanism over the car tracks, sidewalk crossings, stony streets and rough places found in all our American cities. In the lighter vehicles, particularly those of moderate price, the small wheel diameter is still retained, but even here the effect of the advance in public opinion can be seen, for tire sections have often been increased.

Points on Clutches and Brakes

The clutch is the device by which the gasoline engine is enabled to pick up its load gradually and smoothly, and having gotten it started, continued to transmit the power positively. The brake is a device for absorbing the energy stored in the vehicle, gradually and smoothly, until the vehicle comes to a standstill, when it positively holds against further motion until the brake is released. Both devices are in almost constant use while an auto is being driven. Often the brake is applied without disengaging the clutch and often the clutch is let in with the brake still partly applied. Although working in reverse directions their service is identical and there is no reason why a good brake may not be substituted for the clutch, or a good clutch substituted for the brake.

It is a peculiar manifestation of habit, imitation, or like thinking among designers that the brakes in common use very closely resemble each other and are with few exceptions what is known as band brakes, consisting either of a constrictive band to grip the outer surface of the drum attached to a rear wheel, or expanding bands adapted to enlarge into the inner surface of this drum. And, in fact, most cars are fitted with both these, generally on the same drums, but sometimes on different drums.

In a few instances shoes take the place of the bands, but these are usually several in number and closely resemble the band construction, one of the exceptions being the Duryea brake, which is a small steel shoe resembling the horse vehicle brake.

In clutches a considerable variety is found, some of them being expanding bands, some contracting bands, but by far the greater number are of the cone type, or of the multiple disc types. The cone clutch gets a gradually increasing friction by being forced into a cone surface in the flywheel, until it takes up the load and drives positively. Its shape, however, renders it easily withdrawn whenever desired to unclutch. Generally this type of clutch is faced with leather to render it more smooth in operation, and it is found on a wide variety of automobiles, such as the Mitchell, Regal, Moline, Overland, Stoddard-Dayton, Pullman, Mora, Pennsylvania, National Speedwell Marmon, Standard, Acme and Welch. Among the users of the multiple disc are the Austin, Premier, Glide, Dorris, Ohio, Jackson, Marion, Pierce, Maxwell, Overland, Ford, Reo, Brush and many others. The Atlas employs an internal expanding ring clutch. The Midland clutch is of the floating disc type. The Moon has expanding bands, and a number of others forms are used.

Why this wide variety of clutches and closely followed single design of brake is a question the designers themselves cannot answer.

Owing to the Difficulty in finding a suitable course for the two speed trials during the Prince Henry tour, there has been a delay in publishing the propositions. The one flat race is to be held in the vicinity of Berlin; the second was almost definitely fixed for the Limburg-Weilburg stretch of the Taunus course, but on second consideration there are too many turns here to permit the vehicles being fully extended over so comparatively short a distance, and a route is being searched for on Alsatian territory. The second event may be run in the Hagenau Forest.

COLUMBUS SHOW OPENED BY OHIO'S GOVERNOR

COLUMBUS, O., Dec. 27—Under conditions most auspicious, the first automobile show in the history of Columbus, and one of the first shows in the Middle West for the present season, was officially opened Christmas night at 8 o'clock by Governor Judson Harmon of Ohio. The chief executive of the Buckeye State by a slight pressure of an electric switch turned on the current which lit up thousands of lights in every part of the huge Columbus Auditorium, where the display is taking place. The act of the governor was prefaced by a few remarks in which he commented on the rapid strides being made by the automobile industry and the good work being done by the Columbus Automobile Club, under which organization the show is being held.

There were about 83 cars on exhibition when the show opened, and because of the congested condition of traffic on the railroads a few cars were delayed. They were placed on exhibition later in the week. Every available square foot of space is taken up with the automobile and accessories displays, and the first night the crowd was all that could be desired. It was society night, and the "400" of Columbus was out to view the 1910 cars. The cars are exhibited entirely by dealers with the exception of local factories, which fact added more local interest to the show. The number of different makes numbered 43.

When the doors of the huge auditorium were thrown open and the crowds rushed in, surprise and appreciation were expressed on all sides for the beautiful decorations. The interior of the hall is covered with white bunting trimmed with red. Everything is in keeping with the Yuletide period. Opposite the entrance is a huge automobile wheel constructed out of hundreds of various colored electric lights. Scattered in excellent order throughout the hall are many artificial palms and other flowering shrubberies which were decorated with many colored electric lights. The floor is covered with green burlap, which affords an excellent background to display the cars to the best advantage.

One of the features of the decorations is a large number of canary birds which are concealed in the foliage of the artificial shrubberies. When the lights were turned on by the governor the birds started to sing, and this, together with the orchestra, which rendered music at frequent intervals, completed the stage setting for what has been pronounced one of the most beautiful of shows.

Special rates have been granted by the Central Passenger Association, and it is believed that fully 50,000 visitors will pass through the doors during the week.

The proceeds from the exhibition are to be used in erecting a clubhouse for the Columbus club, a large and flourishing organization. The committee on arrangements consists of Perin B. Monypeny, chairman; Herman Hoster, Harry D. Sims, Norman O. Aeby and Dennis Kelly. Max Morehouse is president of the club, and Arthur Crumrine is publicity agent.

The complete list of exhibitors and cars shown are as follows:

O. G. Roberts & Co., Stearns, Stoddard-Dayton, Overland, Lexington, Jackson.

Love Automobile Co., White gasoline, Cole "30."

Maxwell-Briscoe Columbus Co., Maxwell.

Broad-Oak Auto Co., Pierce-Arrow, Chalmers-Detroit, Hudson.

Kimmel Bros., Speedwell.

R. C. Wescott, Regal.

Ohio Motor Car Co., Ohio.

Franklin Motor Car Co., Franklin, Reo.

Central Ohio Motor Car Co., Oldsmobile, Oakland.

Studebaker Automobile Co., Studebaker, E. M. F. "30," Flanders "20."

Early Motor Car Sales Co., Rambler, Babcock Electric.

Columbus Buggy Co., Columbus Electric, Firestone-Columbus.

McDonald Auto Co., Buick.

Robert F. Boda Auto Co., Mitchell, National.

Charles Schlear Motor Car Co., Hupmobile, Velie.

American Auto Co., American "40" Traveler.

United States Carriage Co., Rauch-Lang, Apperson, Great Eagle.

F. E. Avery, Packard, Waverly Electric.

Curtin-Williams Co., Cadillac, Peerless, Winton.

Oscar Lear Automobile Co., Frayer-Miller trucks.

W. A. Paterson, Paterson.

Franklin Cycle and Supply Co., Demotcar.

Accessories: Welton Auto Fender Co., fenders; Williams & Schlereth, tire inflaters; Barndt-Johnson Auto Supply Co., automobile bodies and supplies; Cleveland Puncture Proof Tire Co., tires; Central Ohio Oil Co., oils; A. C. Edwards, motorcycles; Columbus Auto Brass Co., lamps and parts; Rubber Tire Repair Co., repaired tires; Motor Supply Co., automobile accessories; Eckel Tire & Rubber Co., tires.

BLUEGRASS SHOW TO BE IN LOUISVILLE

LOUISVILLE, KY., Dec. 24—The Louisville Automobile Dealers' Association has decided to hold a show next March. At a meeting of the dealers a committee was appointed to select a place for holding the exhibition. No definite decision has been reached, but it is generally expected that an effort will be made to secure the Armory, said to be the largest building in the South. Several new members have been admitted to the association recently, and the exhibition this year will be on a much larger scale than ever before.

PORTLAND PREPARES FOR FOURTH ANNUAL

PORTLAND, ME., Dec. 27—According to Manager F. M. Prescott, Portland's fourth annual auto show will be held during the last week in February. It gives every assurance of being the biggest and best yet held. All the floor space has already been rented, and there are only a few sections in the basement of the big Portland Auditorium which yet remain to be taken.

That the space for the show has been in such early demand is due to the fact that Maine dealers are looking for the biggest business in 1910 the State has ever enjoyed.

BALTIMORE CLUB'S SHOW IN FEBRUARY

BALTIMORE, Dec. 27—The fourth annual automobile show to be held in Baltimore, and the second one to be under the direction of the Automobile Club of Maryland, will take place February 22 to 26, inclusive, at the Fifth Regiment Armory. This announcement was made by President C. Howard Millikin, of the club. It will follow the exhibition in Buffalo. It was originally intended to have the display the latter part of January, right after the Philadelphia show, but it was not certain that the Armory could be had. When the Regiment officials gave their consent Washington had taken the January dates.

RAMBLER HOLDS OWN NEW YORK SHOW

Following its custom, the Thomas B. Jeffery Company will not exhibit at either of the New York shows. However, to afford the many show visitors a better opportunity than usual to view the 1910 Rambler models, the Rambler Automobile Company of New York announces that it will hold an exhibition in its showrooms, at 38 and 40 West Sixty-second street, just off Broadway, during the fortnight from January 1 to 15. Invitations have been issued to the trade, and all interested are asked to attend.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

THE SHOW IS NOW THE THING

Shows are a source of considerable expense to the automobile industry, and the day may come when possibly one national event of this character will answer for the entire country. One is inclined at this time to believe that a series of national exhibitions will be found the most advantageous in a country of such wide expanse wherein the motor-driven vehicle is certain to succeed all horse-drawn carriages and wagons. Once a year there comes the annual outcry about the disorganizing effect of the show circuit, with its utilization of the time and energies of the entire factory, from the highest officer of the company down to the minor employees. Frequently an inventory of the results fails to supply any substantial gains except of an indirect sort, and the impetus given to the industry itself is frequently lost sight of, though in this all makers of cars and accessories unquestionably benefit and to a far greater extent than many of them imagine.

Under the present plan, local shows more than support themselves, and are no longer a drain upon the manufacturer. Thus the show proposition reduces itself to national exhibitions alone. New York is a necessity: Chicago is equally and perhaps even more essential; and the day is near at hand when a third show of national calibre may be required to satisfy the great country beyond the Rockies, which, with its magnificent distances and widely scattered cities, finds greatest use for the automobile in the conduct of commerce.

First of the New York affairs again comes in the Grand Central Palace show, under the auspices of the American Motor Car Manufacturers' Association. Housed in a building which is illy prepared to meet the needs of a vehicle display, the promoters have accomplished wonderful things in fitting the ungainly structure for the really extraordinary unfolding of 1910 automobile products which will be available to the public, beginning to-morrow afternoon and evening and extending for a week thereafter. Here one will see how great the industry has expanded, for this show contains all the newcomers who have qualified to obtain a place in the procession.

With the gradual disappearance of patent litigation difficulties there comes the prediction that another year may see a fortnight in Madison Square Garden for the public telling of the story of automobile-making, for, unfortunately, it is a fact that even this big amphitheater and its overflow halls and basements cannot total sufficient room to meet the entire situation. Hence, there might come a week for those who were first on the scene, followed by the appearance of others entitled to showroom in the big tent.

But the 1910 metropolitan show fixtures call first for a visit to the Grand Central Palace, and then the sequence follows in Madison Square Garden. It will be a most reassuring and wonderful assembling of all that appertains to automobiling; and nowadays, the man who buys never runs the risk that was involved in the earlier purchase of motor-propelled vehicles.

When the first show was held in Madison Square Garden ten years ago, space was so abundant that about half of the main floor was taken up by a track. Around this the cars on exhibition were run, at the request of prospective buyers, to show that they really would go. Outdoor demonstrations did not come into vogue till several years later. To those who can recall these earlier exhibitions that of 1910 will be a notable contrast.

To-day to New York City the two annual automobile shows are perhaps the greatest events, in that line, of the whole year. The horse show, their natural rival, has admitted defeat, on the unanimous decision of the hotel-keepers that it was far outstripped in attendance. Other exhibitions which might have competed, such as those of electrical and business appliances, have been "out of the running" for several years.

A survey of the past decade brings with it a realization of the great progress made in automobile manufacture. In some of its aspects the improvement is stupendous in its proportions, and herein the man who intends to add aerial travel to his automobile accomplishments bases his hopes for early progress in this direction. Mayhaps that which came about in France may be repeated in this country—the replacing of the automobile show with an exhibition of aeronautical craft. In this country the indications are that we shall have both, and the second in a sporting rather than in a practical sense.

TENTH GARDEN SHOW WILL BE MOST ARTISTIC

WHILE chickens are cackling overhead during the session of the Poultry Show, carpenters, designers, plasterers, painters, and signmakers are zealously engaged in the basement of Madison Square Garden preparing the details of the magnificent decorative setting for the cars to be exhibited at the Tenth National Automobile Show. Next week they will take possession of the entire building, and the work will be pushed night and day until 8 o'clock on Saturday evening, January 8, when the doors of the Garden will be open from noon Friday, January 7, to 6 o'clock Saturday evening for the installation of exhibits.

The Garden show each successive year is proclaimed by the public and the tradesmen to be a bigger and better one in every way than its predecessor. This verdict is due chiefly to the untiring efforts of the show committee, who are the pioneers in many methods of show management that are now generally accepted in this country and abroad as a matter of course. The show committee is composed of Col. George Pope, chairman; Charles Clifton, and M. L. Downs, secretary.

Col. George Pope is a pioneer in the automobile industry, having been connected with it since 1897. He is treasurer of the Pope Manufacturing Company, and has been chairman of the A. L. A. M. show committee for four successive years.

Charles Clifton has been prominently identified in the industry since 1898. He is the president of the Association of Licensed Automobile Manufacturers and treasurer of the George N. Pierce Company.

Merle L. Downs, secretary of the committee, managed several big automobile events in the early days of racing and touring. He has been in many branches of the automobile business, and for the past six years has attended to the detail work in connection with all the A. L. A. M. shows.

Coker F. Clarkson, the assistant general manager of the Association of Licensed Automobile Manufacturers, though not a member of the show committee, has been prominently identified with it. Mr. Clarkson is a lawyer who found a greater interest in engineering matters, and from electrical experimenting he stepped into the A. L. A. M. as secretary of its mechanical branch. He has edited various engineering publications which have been most favorably commented upon by the engineering profession. He is the compiler of the A. L. A. M. handbooks.

CHICAGO SHOW TO HAVE NOVEL DECORATIONS

CHICAGO, Dec. 27—The ninth annual automobile show, held in this city February 5 to 12 under the auspices of the National Association of Automobile Manufacturers, will prove a revelation to the automobile world in its decorative scheme, if in nothing else. Manager Samuel A. Miles believes that he has succeeded in his aim to present a setting that will in no way permit of comparison with past efforts. In short, this show will be held in a forest.

This will necessitate the use of about 100 real trees, of which twenty will be two feet in diameter and seventy feet high; about a mile and a half of brick wall, real bricks; and the same amount of vine-covered iron railings; about 80,000 square feet of trellis work and pergola; 150 ornamental vases; 200,000 leaf sprays and flowers; four fountains of real water, and 150,000 square feet of paintings. No sign of the roof will be visible. The walls and the roof will be entirely covered with foliage and blue sky.

Mr. Miles reports that he has assigned spaces to 250 manufacturers of automobiles, motor cycles, part and accessories for the coming show. The list of automobile exhibitors includes the names of many new firms which have come into the limelight since the last exhibition. In order to accommodate more exhibitors this year it was found necessary to limit the spaces. In all, ninety-five automobile manufacturers have been given spaces on the main floor of the Coliseum and the Annex, the basement of the Annex and the main floor of the First Regiment armory.

The motor cycle department will again be an interesting feature. Spaces have been assigned to twelve makers of the two-wheelers on the second floor of the Annex. The parts and accessories firms have been taken care of in the galleries of the Coliseum and the First Regiment armory. As usual, the Chicago show will be national in its scope, and both licensed and unlicensed makers will exhibit their products under the same roof.

A. A. A. MEETINGS DURING SHOW WEEKS

THE American Automobile Association will have space at both the New York shows. Representatives of the association will be in attendance, and members are invited to make use of the booth, where a telephone will be provided and everything possible arranged for their comfort. At the Grand Central Palace show headquarters will be at space 300. At the Madison Square Garden show headquarters will be at space 327 in the Concert Hall.

The Automobile Association of London, with which the A. A.A. has reciprocal arrangements, will have a representative in attendance at both booths and information will be gladly given regarding the facilities afforded by this great motoring organization to those contemplating touring abroad. A.A.A. members can join the A.A. of London upon payment of one-half the regular annual subscription.

During the week of the show at Grand Central Palace the first meeting of the Good Roads Board for 1910 will be held at National headquarters, 437 Fifth avenue, Thursday, January 6, at 10 o'clock, Chairman George C. Diehl presiding.

During the week of the Madison Square Garden show the following meetings will be held at National headquarters, 437 Fifth Avenue, unless otherwise indicated.

Tuesday, Jan. 11, 10 A. M.—A.A.A. Executive Committee monthly meeting, President Lewis R. Spear presiding.

Wednesday, Jan. 12, 11 A. M.—Legislative Board, Chairman Charles Thaddeus Terry, presiding.

Thursday, Jan. 13, 10 A. M.—Directors' meeting, New York State Automobile Association, President H. A. Meldrum presiding. To be held at Hotel Belmont.

Thursday, Jan. 13, 2 P. M.—Touring Information Board, Powell Evans, Chairman, presiding.

Friday, Jan. 14, 10 A. M.—Second Annual Reunion A.A.A. State and Club Secretaries, Frederick H. Elliott, Secretary, presiding. Luncheon at 1 o'clock.

A.A.A. members holding certificates for reduced railroad rates should present the same for validation promptly.

COURT RULES E-M-F CAN SELL INDEPENDENTLY

DETROIT, Dec. 27—According to the finding of Judge Severens, of the United States Circuit Court, the E-M-F Company of this city was fully justified in rescinding the selling agreement it entered into with the Studebaker Automobile Company, last April, and is at liberty to handle its own product.

Some two weeks ago President Walter E. Flanders, of the E-M-F Company, it will be recalled, abruptly terminated the relations up to that time existing between the two concerns, serving notice on the Studebaker Automobile Company that thereafter the Detroit concern would market its own products. The Studebaker officials, who constituted the minority stockholders in the E-M-F Company, immediately sought to have Judge Swan, of the local United States Court, issue a peremptory restraining order against the E-M-F Company, to prevent the summary severance of relations and the selling of cars through any other medium than the Studebaker Company. Judge Swan declined to take this step, stating that he would decide the case on its merits as they might be presented to him on a date set. Then counsel for Messrs. Fish, Studebaker, and Eames, of the Studebaker Company, stole a march by securing a temporary restraining order from United States Circuit Court Judge Severens, of Cincinnati.

When the matter came up at Kalamazoo, Mich., last Friday, for final settlement, Judge Severens denied the application of the Studebaker officials for an injunction to prevent the E-M-F Company selling its cars to independent dealers, holding that the latter company was justified in rescinding the selling agreement, whose alleged non-fulfillment on the part of the Studebaker Company proved the bone of contention, and leaving the Detroit company free to market its cars as it sees fit.

The only point questioned by Judge Severens at the preliminary hearing was whether the action of the majority directors was really the corporate act of the company. In rendering his decision, Judge Severens did not touch upon this phase of the matter, evidently having satisfied himself fully.

Immediately after the reading of the decision counsel for the Studebakers called attention to the fact that there was pending before Judge Swan in the United States circuit court here another case, brought by the Studebaker Automobile Company, and asked Judge Severens to hear it, on the grounds that he was already familiar with the facts, and that Judge Swan would not be able to do so. Counsel for the E-M-F interests promptly question Judge Swan's inability to handle the case, and after considerable argument on both sides, Judge Severens stated he would hear the case if Judge Swan requested him to do so, but that under no other condition would he interfere. Studebaker counsel pressed the point, and acting on the supposition that Judge Swan would not hear the case, it was set by Judge Severens for a hearing at Cincinnati, January 3.

It developed that what the Studebaker Company really was after was another restraining order which would tie the E-M-F officials up until the other case could also be heard, thus causing another ten days' delay. When the matter was put up to Judge Swan he promptly declared that inasmuch as the original action had been taken before him he considered it his duty to hear it, and set the case for Monday morning, December 27.

Latest Move in Court

DETROIT, Dec. 28—When the Studebaker case against the E-M-F came up before Judge Swan Monday morning the Studebaker lawyers asked permission to withdraw the motion for a temporary order to restrain the E-M-F company from going on with the sale of cars, and to also withdraw the bill of complaint, without prejudice and at the cost of the Studebaker company. E-M-F attorneys had no objection to the withdrawal of the motion for a temporary restraining order, but, believing that the withdrawal of the bill of complaint was merely a step toward clearing the way for action in some other court, asked that if the court granted such permission it be accompanied by an order estopping further proceedings against the E-M-F company.

Judge Swan promises a decision at an early date.

REAL AUTOMOBILE NEWS FROM THE PINE TREE STATE

PORTLAND, Me., Dec. 27—That the coming of cold weather has little effect upon the automobile business of Maine is clearly evidenced by the figures which have just been compiled at the office of the Secretary of State in Augusta. The record of registration of automobiles, according to the figures, shows that for the past 11 months of the present year 1,614 machines were registered; the number of licenses issued to operators was 1,788; the number of motorcycles registered was 133, and the number of licenses issued to dealers was 42. From these sources the total receipts in fees amounted to $5,486, divided as follows: From registration of automobiles, $3,224; from licenses issued to operators, $3,576; from registration of motorcycles, 266, and from licenses issued to dealers, $420.

During the month of November, when the trade in a State so far north as Maine is thought to be at a standstill, the number of automobiles registered was 34 and the amount received in fees was $68; the number of licenses issued to operators was 30, and the amount received in fees was $60; the number of licenses issued to dealers was four, from which $40 was received.

The number of automobiles which have been registered since the law went into effect in June, 1905, is 4,846, and the number of licenses issued to operators during that time is 5,578. The number of motorcycles registered is 472, and the number of licenses issued to dealers is 123. The total amount received in fees since the law went into effect is $23,012, which is divided as follows: From the registration of automobiles, $9,693; from licenses issued to operators, $11,156; from registration of motorcycles, $944, and from licenses issued to dealers, $1,230.

Reviewing the automobile season in Maine which has just come to a close, it may easily be said to have been the most successful the State has ever enjoyed. Conservative business men, those who at first it was thought could not be brought to the use of the automobiles, have taken up the new means of locomotion, and many of them, although well advanced in years, may be seen about the streets of Portland, Bangor and the other cities of the State driving their own cars. Doctors in particular have recognized the usefulness of the horseless carriage.

Auto Tourists in Plenty—It is estimated from the figures of the Maine railroads that fully 250,000 people visited this State during the vacation season of 1909. That is the number that came by train, but it does not by any means even hint at the thousands that came by automobile. In fact, there has been a general complaint that the automobile has cut into the business of the steam lines, for hundreds of people who formerly came that way have entered the State in their touring cars.

The commercial vehicle has yet to make a pronounced impression in the State, but it is being slowly adopted. Several smaller ones are used in Portland and at Poland Springs and Rockland the Ricker Brothers are using the big Stanley passenger car for the transportation of guests to the mammoth hotels.

BISONS ELECT ENOS TO CLUB PRESIDENCY

BUFFALO, Dec. 27—About seven hundred members of the Automobile Club of Buffalo attended the annual meeting and election of officers. The new official roster includes the following: Laurens Enos, president; Harry Thorpe Vars, vice-president; Dai H. Lewis, secretary; Donald Mackay, treasurer; Edward H. Butler, Charles Clifton, Edwin R. Thomas, George C. Diehl, George P. Urban, John G. H. Marvin and Maurice M. Wall, directors.

A silver loving cup was presented to retiring President John M. Satterfield.

It is the custom of the club that a president shall have only a single year in office. President Satterfield's report reviewed the work of the club during the year, including the launching of the official monthly, the *Buffalo Motorist*, which has yielded a net revenue of $1,698.75 to the club; the institution of the club dashboard emblem, the distribution of road maps, including the new map of Erie County; the automobile show of 1909, which gave a net profit of $2,700 to the club after paying a dividend or rebate of over 51 cent to the exhibitors; the one-gallon gasoline contest which established a new world's record; the warfare against the Williamsville speed trap, in which the club defended all who were arrested and secured a reversal of the convictions in the justices' court and the repayment of all moneys exacted under the guise of fines; the winning of the Glidden and Hower trophies by members of the club; the institution of new steel-enameled road signs; the warfare by the club on automobile thieves, resulting in the recovery of all of the 63 cars stolen and the sentencing of eight of the thieves to prison for terms ranging from 20 days to 3 1-2 years.

The treasurer's report showed a balance of $4,551.19 in the treasury. The club spent $300 in rewards for the arrest of automobile thieves and $212 in smashing the Williamsville speed trap.

Secretary Lewis reported that the club's total membership is 1806, of which 612 were added this year and 105 within the last 30 days.

The club will send a delegation to attend the A. A. A. National Automobile Legislative Convention, which will meet in Washington in February in the interest of a Federal motor registration law and a uniform State law throughout the country.

DENVER MOTOR CLUB READY FOR NEW YEAR

DENVER, Dec. 24—The Denver Motor Club will start the new year with all its objects outlined beforehand and a new set of officers. At the election held recently William D. Nash was elected president, Dr. J. N. Vroom vice president, E. C. Healy secretary and C. P. Allen treasurer. This makes a complete change of officers, with the exception of Mr. Allen, who has held the position of secretary since the organization of the club. The board of governors for the following year consists of the above-named officers with the addition of Morris Mayer, Dr. S. D. Hopkins, W. H. Sharpley, Dr. E. F. Dean and George E. Cartwright.

The work which has been outlined for the coming year embraces a strenuous campaign for good roads, the erection of many new signboards, the biggest and best automobile show ever held west of Chicago (to open March 23), a 290-mile road race on Decoration Day, a reliability contest in June, another road race on Labor Day, an economy contest in October and a hill-climb in November.

Within the last two months the commissioners in Weld, Adams, Jefferson, Douglass and El Paso counties have had a number of men at work on the roads. The club has made a general canvas and has found in almost every section that the land owners, ranchmen and farmers are ready to assist the work in any way. Many of them have offered funds as well as labor, teams and implements.

MILWAUKEE CLUB'S SHOW STRIKES A SNAG

MILWAUKEE, Wis., Dec. 27—Representatives of twenty-five well known makes of automobiles in Milwaukee have issued a public statement announcing that they have mutually agreed not to display their cars in the second annual automobile and motor show of the Milwaukee Automobile Club, in the Auditorium, from February 22 to 27.

"Believing the expense of exhibiting will be greater than the profits to be derived from the show," the announcement says, "we will not exhibit at this coming show." The agencies are:

Mitchell Automobile Co., Mitchell; Rambler Garage Co. of Milwaukee, Rambler; Sanger Automobile Co., Oldsmobile, Maxwell, Stearns; Curtis Automobile Co., Reo; Jonas Automobile Co., Peerless and Cadillac; Welch Bros. Motor Car Co., Packard and Rauch & Lang electric; Akin Motor Car Co., Stevens-Duryea and Columbus electric; Emil Estberg, Pope-Hartford, Waverly and Woods electrics; Hickman, Lauson & Diener Co., Ford; Waite Bros., Moline; Riverview Automobile Co., Moon; Bates-Odenbrett Auto Co., Overland, Marion, Winton; Albert Smith, Palmer & Singer; American Automobile Co., Pierce-Arrow, Apperson, Babcock electric.

Each of the fourteen agencies will conduct private shows in their respective garages. They claim unfair treatment from the Milwaukee club, but the nature of this is not given out. President Clarke S. Drake, of the M. A. C., says that he is not aware of any unfair treatment, and while regretting the attitude of these dealers, believes the club will be able to get along without them. All space has already been contracted for, which gives promise of a show at least 75 per cent. larger than the first show held in the Milwaukee Hippodrome last March.

SALT CITYITES PLAN MUCH FOR 1910

SYRACUSE, N. Y., Dec. 27—The Automobile Club of Syracuse did things during 1909, and its members have a right to congratulate themselves upon results attained. During the Summer a fine room, principally for the convenience of tourists, was located on the second floor of the S. & A. K. building, on East Genesee street. A club publication, the *Spark Plug*, is about to be launched. The club ends the year with a total membership of 390, a gain since the first of July alone of 150. The officers of the club say that in the week remaining of 1909 they'll get another ten, making an even 400 to begin 1910.

The results attained are due principally to the efforts of President Hurlbut W. Smith, Secretary Forman Wilkinson, and the assistant treasurer, Miss Grace L. Tickner, who has proved a veritable dynamo in the interest of the club.

The club was started in 1902, and Fred H. Elliott, present secretary of the American Automobile Association, was its first secretary. The present recruiting movement is the most ambitious one the club has had, and it is by no means finished yet. Five hundred members is the goal, and it is confidently asserted the club will have them by the early part of the Spring. Not only has the club done a great amount of road and danger sign work, but it has had a potent effect upon legislation at Albany.

BAY STATERS INSPECT INTERESTING TESTING DEVICES

WORCESTER, MASS., Dec. 27—The Worcester Automobile Club, Wednesday evening, was given a demonstration at the new automobile testing plant of the Worcester Polytechnic Institute. The apparatus is the invention of Prof. D. L. Gallup, professor of gas engineering in the department of mechanical engineering at the Tech, and the demonstration Wednesday night was the first public one given. The apparatus is on the street level of the building and permits a car to be run in directly to the testing wheels. On the wall facing the driver while his car is being tested is a chart ruled with lines and curves. The horizontal distances represent the rate of speed in miles per hour and the vertical distances the draw-bar pull. From these two factors are plotted curves which represent the horsepower and per cent. of grade. In front of the chart are strung two automatically controlled ribbons, one of which is horizontal but which moves up and down, the other is strung vertically and moves back and forth and represents the speed. The horsepower and the per cent. of grades are indicated on their respective curves by the varying point of intersection of the two ribbons. The apparatus is designed to operate at speeds representing a maximum of 60 miles per hour and a draw-bar pull of 1,500 pounds and to grades of 25 per cent.

In addition to the testing plant Prof. Gallup has on exhibition an optical monograph which, by means of a tilting mirror mounted on a flexible diaphragm can, when connected to the combustion end of a gas engine cylinder, be made to project an electric arc upon a ground glass screen in such a manner as to indicate the changes of pressures which take place in the cylinders. An elaborate piece of apparatus designed to show the effect of different types of ignition and spark plug combinations is also shown. By rotating this device at different speeds the conditions and reliability of the sparking devices can be shown as they would occur if the automobile was running at different rates of speed.

NEW OFFICERS AND NEW CLUB HOUSE

New Rochelle, N. Y., Dec. 24—Very commendable was the meeting of the New Rochelle Automobile Club held recently. This was the annual meeting, and officers were elected as follows: President, W. B. Ogden, Jr.; first vice-president, Edmund Eckart; second vice-president, G. W. Bennett; treasurer, F. D. Le Count; secretary, F. M. Carpenter. The sum of $4,000 was subscribed as the first payment on the new $25,000 club house. The activity of the club has resulted in the reduction to the ranks of an obnoxious motorcycle officer and the putting of the other plain-clothes motorcycle officers in uniform. By its prompt action in this case the club gained many friends.

A. C. OF PHILADELPHIA PASSES 1,000 MARK

Philadelphia, Dec. 20—At last week's meeting of the board of governors of the Automobile Club of Philadelphia, Secretary S. Boyer Davis' report showed a total membership of 1,014. The passing of the thousand mark has given impetus to the club-house idea, and Chairman D. Braden Kyle, of the club garage committee, who has been quietly investigating the matter during the past twelvemonth, is said to be loaded to the guards with data, which, when presented to the club at a meeting in the near future, will result in the authorization to go ahead with the work of providing splendid headquarters for the club in the central part of the city. Besides the garage and the usual equipment of the up-to-date club house, the plans contemplate a library and squash and handball courts.

The Automobile Club of Germantown is continually outgrowing its splendid quarters at Carpenter and Emlen streets. Two additions have already been made to the original building, and now numerous local architects are estimating on a 62 x 90 feet addition that will cost $15,000, the work to be begun next Spring.

QUAKERITES ARE BUSY THESE DAYS

Philadelphia, Dec. 27—The Quaker City Motor Club will present each member with a copy of the 1910 "Official Automobile Blue Book" as a New Year token. President Berger will name two delegates to attend the National Legislative Convention of the A. A. A. at Washington, D. C., next February. A donation of $100 was made to the pension fund of the Fairmount Park guards. The annual dinner, Thursday, January 6, at Hotel Walton, promises to be a record-breaker. A feature of the affair will be an exposition of the new rules of the A. A. A. Contest Board by Chairman S. M. Butler.

A mix-up with the Contest Board has necessitated the postponement of the New Year's run of the Century Motor Club. An eleventh-hour change in the entry blank, which was insisted upon by the chairman, allowed insufficient time for the securing of new entries, and the run may be held during the coming show of the Philadelphia Automobile Trade Association January 15-29.

THE AUTOMOBILE CALENDAR

Shows and Meetings.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 4............New York City Automobile Club of America. Annual Meeting, Society of Automobile Engineers.

Jan. 5............New York City, Waldorf-Astoria Hotel, Annual Meeting Motor and Accessories Manufacturers, Inc.

Jan. 7............New York City, Manhattan Hotel, General Meeting Manufacturers' Contest Association.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Jan. 13...........New York City, Engineers' Society Building, Adjourned Meeting, Society of Automobile Engineers.

Jan. 17-22........Philadelphia, Second Regiment Armory, Automobile Show. J. H. Beck, Secretary, 216 Odd Fellows' Building.

Jan. 17-22........Kansas City, Mo., Annual Automobile Show of the Motor Car Trade Association of Kansas City. P. S. Sutermeister, Secretary, Midland Building.

Jan. 24-29........Detroit, Wayne Hotel Gardens. Third Annual Automobile Show, Detroit Auto Dealers' Association. John Gillispie, Manager, Hotel Tuller.

Jan. 24-31........Washington, D. C., Convention Hall, Automobile and Aeronautical Show, Automobile Dealers of Washington. B. R. Johnson, Manager, 1313 New York Avenue, N. W.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Feb. 14-19........Buffalo, N. Y., Broadway Arsenal, Eighth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, Manager, 760 Main Street.

Feb. 14-19........St. Louis, First Regiment Armory, Fourth Annual Automobile Show, St. Louis Automobile Manufacturers' and Dealers' Association, Robert E. Lee, Manager, 1629 Washington Avenue.

Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show. New Jersey Exhibition Company.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show. Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South Street.

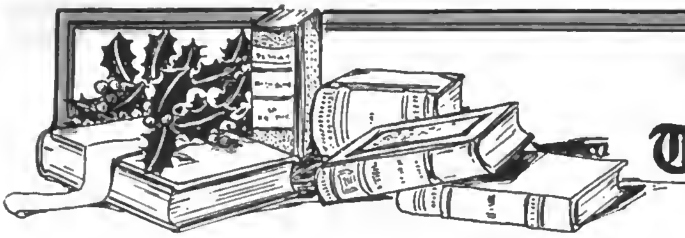
Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3....Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Secretary.

March 5-12.......Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.



The Law and The Automobile

WHAT MICHIGAN'S NEW LAW CONTAINS

DETROIT, Dec. 27—Several important changes are embodied in the motor vehicle laws, which go into effect January 1. Under the new order of things all registrations will expire December 31 of each year, and may be renewed at a cost of $1. Each new registration will hereafter cost $3, instead of $1, as formerly. It will also be compulsory for every purchaser of a second-hand machine to deposit $1 with the secretary of state, and any dealer or individual selling a second-hand car must report the sale to the secretary of state's office within ten days.

Hereafter the driver of an automobile obstructing a highway must turn out for a motor car. At the same time the driver of the car must use every precaution to prevent the frightening of horses, and it becomes the legal duty of occupants of a car to render all possible assistance in the event of trouble.

The state law takes cognizance of the power of municipalities and townships to regulate the speed of automobiles, but in no event must the rate prescribed by them exceed the provisions of the state law, which is 25 miles in the country, and 10 and 15 miles respectively in the business and residence portions of cities. Upon approaching a pedestrian or team in the highway the motor car must be slowed down to 10 miles an hour, and notice of its coming must be given. Numbers must be displayed conspicuously on the front and back of each machine, and different colors will be designated each year.

A MARYLAND LEGISLATOR WITH A GRUDGE

BALTIMORE, Dec. 27—Former Mayor John A. Garrett, of Glen Echo, Montgomery County, noted as a terror to Washington and Maryland speedists, announces that he is going on the warpath again. He has been elected a member of the coming General Assembly of Maryland and he says that it was his purpose, in securing the election, to carry the battle against autoists to the legislature. Now he wants a special law which will permit the Montgomery County commissioners to impose a tax on autos that use any of the County's highways. This money he would employ in establishing a corps of special officers to patrol the County against speedists, particularly of Washington and the lower sections of Maryland. He says that these cars in the hands of speedists injure the roads more than any other kinds of vehicles combined. Glen Echo will be remembered by all who had occasion to pass through there during the last few years as the site of a particularly obnoxious trap, which the Automobile Club of Maryland finally succeeded in breaking up.

KENTUCKIANS CELEBRATE GOOD ROADS LEGISLATION

LOUISVILLE, KY., Dec. 20—Automobilists, senators, mayors, merchants, and those who fought in the trenches for the cause assembled in the leather room of the Seelbach Hotel, Friday evening, in celebration of the victory of the Kentucky Good Roads amendment to the constitution. About eighty were present, and the betterment of the State highways was discussed from every angle. The affair began shortly after 8 o'clock with a banquet, over which Dr. Ben L. Bruner, Secretary of State, presided as toastmaster. What the amendment means to Louisville, Kentucky, and the farming and automobile industries of the State was the keynote of the addresses made by Senators Joseph F. Bosworth and G. T. Wyatt, Mayor William O. Head, Julius V. Beckmann, secretary of the Kentucky Good Roads Asssociation, and M. C. Renkin, State Commissioner of Agriculture.

PENNSYLVANIA'S LAW IS NOW EFFECTIVE

PHILADELPHIA, Dec. 27—On Saturday morning next one of the most important provisions of the Keystone State's new automobile law will go into effect for the first time: that requiring the registration of cars and the licensing of drivers. It will be recalled that when the present law went into effect last Spring an exception was made of the clauses governing registrations and licensing, it being stipulated that in this particular the old law should remain in force until January 1, 1910. The new schedule provides for a sliding scale in registry charges—less than 20 horsepower, $5; 20 horsepower and less than 50 horsepower, $10; 50 horsepower and over, $15 per annum. Owners or their relatives who might drive are not compelled to take out licenses, but paid chauffeurs will be required to pay $2 each and to wear the official badge while on duty.

MICHIGAN'S NEW LAW SOON EFFECTIVE

LANSING, Mich., Dec. 27—There will be 15,000 automobiles in use in Michigan in 1910, according to the Secretary of State's office. Twelve hundred licenses were issued in 1909, and an increased number is expected this year. The fee for registration under the new law going into effect January 1 has been increased from $1 to $3.

Some of the provisions of the new law are a gain for users of automobiles. One provision makes it the imperative duty of teams ahead of an automobile to turn out and let the automobiles go by. A speed of 25 miles an hour is the limit allowed in the country, and in the cities 15 in the residence portion and 8 in the business portion. Numbers are to be displayed on both ends of the machine.

DELAWARE WANTS NO JOY RIDING

WILMINGTON, DEL., Dec. 6—Two city departments, the water department and street and sewer department, having provided themselves with automobiles for the use of their officers, *Every Evening*, a local newspaper, makes the suggestion, editorially, that all municipal machines be plainly lettered with the name of the department to which it belongs, one object being to guard against misuse of the machines by subordinates. There is reason to believe that in this respect some of the employees have been imitating the practice in certain larger cities.

There Is Hope! In his address to the grand jury of Potter County, Pa., Judge Ormerod, who, perhaps, never noticed them in his horse-driving days, called attention to the numerous "thank-ye-ma'ams" on the roads of that hilly country, characterizing them as "nuisances that must be abated." The judge has become an ardent automobilist, and the judicial ventebræ have doubtless been oftentimes severely wrenched by these relics of a bygone age of road building, to call forth such a bitter arraignment.

The Interesting Law Suit between the Cannstatt Daimler Company and the Swiss motor car firm of Niegevet & Cie. has now been concluded after having been carried from one court to another. The Swiss high court, which had to definitely settle the plea for damages for infringing the Daimler radiator patents, fixed the sum Niegevets have to pay at 300,000 francs; Daimler demanded no less than 7,673,000 francs indemnity.

MOTORCYCLE TROUBLES

Editor THE AUTOMOBILE:

[2,131]—Will you please favor me with an answer to the following: I have a 4 horsepower air-cooled motorcycle which does not have as much power as it ought to on very steep hills. The compression is good, the timing as it should be, valve springs are right, but motor will run very fast on the level, very well on slow speed, having great pulling power when throttled down on moderate grades, yet when the throttle is wide open, the machine does not do what it should. What should I look for as the trouble? What should be the clearance space with a 3½-in. piston, on an air-cooled engine? The motor uses an excessive amount of oil, which leaks out around the valves. If I do not use enough, smoke comes out around the crankcase. Would this indicate that the piston was too small? C. O. W.
Binghamton, N. Y.

Either the throttle valve is loose on its shaft or else all of the good things which you enumerate are not actually in existence on the machine at one and the same time. The loosened throttle valve would account for the very good pulling powers of the motor at slow speeds, that is, the throttle was probably open wider than you thought. On this basis, you expected to get much more power in proportion at wider openings, which could not come true for the reason that the throttle could not open any wider.

As to the clearance, that depends entirely upon the compression desired. Knowing the latter you can easily figure the former, or if you know what figure the manufacturer claimed as the latter, you can figure out what that means and check up on your cylinder to see if you have it. Thus, for a compression pressure of 50 pounds (gauge), the compression space should be roughly 47 per cent of the piston displacement; for 60 pounds, 41¼ per cent; for 70 pounds, 36¼ per cent, and for 80 pounds, 32 per cent.

This piston displacement is the area of the piston in square inches multiplied by the stroke in inches. While the usual compression pressures in motorcycles is not definitely known, in air-cooled automobiles, 50 to 60 pounds is more used than the higher pressures. From this, you would apparently want to find your engine giving between those two figures. Midway between the two would mean about 44 per cent of the piston displacement.

Just to show you how to figure it, suppose the stroke which you have not given is 3½ in., then the area of the piston is 9.62 sq. in. Then, the piston displacement is 9.62 by 3½, which is 33.67 cu. in., 44 per cent of this is 14.82 cu. in. for the clearance, or 48.49 cu. in. total.

GEAR RATIO'S INTEREST

Editor THE AUTOMOBILE:

[2,132]—What in your opinion is the best gear ratio for both three and four-speed transmissions, that is, the most practical and satisfactory, all things considered? Please give your answers in numbers of the crankshaft turns per one of the rear wheels. How are the Peerless "30", the Packard "30" and Stearns "30-60" geared? RATIO.
Albany, N. Y.

This is a subject on which very little information is available, strange to say. It also varies greatly from one make to another, with the size of wheels, inclination of owner, country to be used in, service, etc. Thus, hill climbing calls for a much lower gearing ratio than ordinary use, while speed work calls for a much higher ratio.

Some of the cars which you mention are available, thus: Peerless 19 had 2.85 ratio on high with 36-in. wheels; Peerless 25 had 2.59 ratio on high with 36-in. wheels; Stearns 15-30 has 3.5, 4.8, and 10.6 to 1 respectively on high, intermediate and low gears, with 34-in. wheels; Stearns 30-60 has 2.78, 3.77, 5.5, and 11.2 to 1 respectively on high second, third, and low with 36-in. wheels.

Other gear ratios which may interest you are: Stevens-Duryea Model X, 3 to 1 with 34-in. wheels; Winton Sixes (both) 3.69, 3.2, 2.937, or 2.64, choice of these for high gear; 45 has 34-in. wheels and 60 has 36 in.; Thomas 16 town car, 4 to 1 with 34-in. tires; Thomas 6-40, 3.5 to 1.36-in. wheels; Thomas 4-50, choice of 2.78, 2.6, 2.36, 2.23 or 2.18 on high, with 36-in. wheels; Thomas 6-70, same as 4-60. There is remarkably little information available on this subject.

WOOD ALCOHOL IN FUEL

Editor THE AUTOMOBILE:

[2,133]—The writer has been told by a mechanical engineer that, if once a month one gallon of wood alcohol be introduced into the gasoline with the 14 gallons of gasoline and allowed to serve the cylinders through the carbureter as a fuel, this will result in keeping the spark plugs and cylinder interior free from carbon. What is your opinion on this subject? H. L. HOPKINS.
New York City.

It is doubtful if the wood alcohol and gasoline in the proportions you mention, will mix, the former simply floating on the latter. In that case, it is hard to see what good it will do. Similarly, with its use as a fuel, if it does not mix thoroughly with the gasoline, it will not burn at the same time as the latter, but separately, which would result in a very peculiar action on the part of the engine. That is, the alcohol would call for one adjustment of the carbureter and the lighter gasoline, another.

While the use of alcohol may not cause as much carbon to be deposited on the spark plugs and the interior of the cylinders, its use brings out other equally undesirable features, for instance, it is said to corrode valves and valve seats, eating into them in much the same manner that a weak acid or strong alkali would.

TWO-CYCLE ENGINE POWER

Editor THE AUTOMOBILE:

[2,134]—Please answer through the columns of "Letters Interesting, Answered and Discussed" what would be the power of a one-cylinder, two-cycle, three-port engine for an automobile having a 5-inch bore and stroke? B. H. M.
Morgantown, W. Va.

For automobiles, the usual rating used for two-cycle engines regardless of the number of ports or type, is the same as that for four-cycle, the assumption being that since the greater amount of power per cylinder has not been proven, the two are equal. On this basis, the size cylinder you mention (5 in.) would rate at 10 h.p.

A formula which has been advocated by Roberts, the two-cycle authority, gives a rating for this size depending upon the speed at which it is run of: at 1,000 r. p. m., 9.3 h. p.; at 1,200 r. p. m., 11.0 h. p.; at 1,500 r. p. m., 14.0 h. p. It is doubtful if the latter speed can be attained with a two-cycle engine, however.

Another rating formula advocated by the A. P. B. A. for marine racing engines gives this engine a maximum power of 9.6 h. p. For other marine use, the rating is but 2/3 of this or 6.4 h. p. In this, you should bear in mind that the figures are for very slow speed work such as is common with motor-boat engines.

CURE FOR KNOCKING

Editor THE AUTOMOBILE:

[2,135]—I note in your answer to letter number 2,102, relative to knocking in the two cylinders 2 and 3 that you suggested coil trouble. I had a similar experience, and when I tightened up the center bearing of the crankshaft the knocking stopped. Although the distance from the two bearings is short, nevertheless, the pressure in the center from the two cylinders, one on each side, would certainly spring the shaft enough to cause a knock if there was any play. Of course, the cylinders fire alternately with number 1 and 4, so that the knocking would not show much when the engine was running at high speeds. If the trouble was in the coil, he could change the connections 2 and 3 to the outside without much trouble.
Reger, Mo. PLATT OVERTON.

The first idea is a good one, but the last named, that is, the interchanging of terminals could not be done, as the timing would then be defective, and the engine would not run at all. If a wire was connected up to cylinder number 1 and then changed as this writer suggests to lead to cylinder number 2, the result would be that cylinder 1 would receive a spark at the correct time for number 2 and, vice versa, cylinder 2 would get a spark at the right time for cylinder 1. This would of course be incorrect for both, and the engine actually would not make a revolution, after this change had been made.

Answered and Discussed

COLLISION LIABILITY

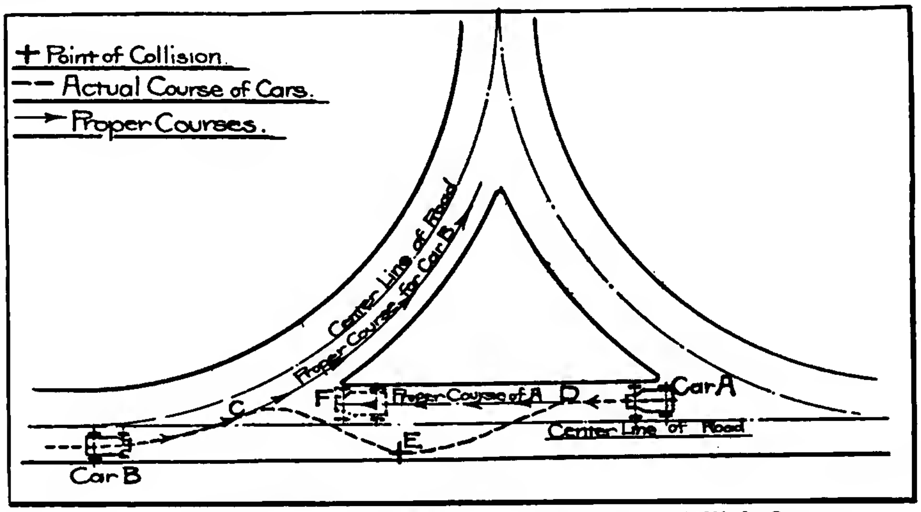
Editor THE AUTOMOBILE:

[2,136]—Will you please advise me as to the liability in the following case: If A driving an auto meets B also driving a car, the latter (B) giving a signal by means of his hand that he is going to turn around to his (B) left following the curve of the road at that point. A slacks up, and thinking to give B more rooms, turn to his own (A) left. B starts to turn to his left, then apparently changes his mind and turns back to his right, running into A at the point marked E. Which is to blame? N. W. L.
Plainfield, N. J.

The sketch below shows the scene of the collision, and the layout of the roads there, with two forks from the main road branching together to form a Y. Car B followed the course B C E as indicated by the heavy dotted line, while the other car proceeded along as per A D E, also indicated by heavy dotted lines.

As the case is told by the writer above, it appears as if the liability lies with A, although in turning out as he did he showed a kind heart and a tendency to think for the other fellow. Nevertheless, when he crossed the center line of the road at point D, he went wrong and for that he would be liable. His proper course would have been to proceed in a straight line as shown by the arrows, up to the intersection of the two roads F, where he should have thrown out his clutch until B passed or until the road was otherwise clear.

Had he done this, and had B driven as he did, changing his mind and his course at C, A would have been on the right side of the road somewhere between D and F, but wherever he was, he would have been in the right. Then, had B run into him, the latter (B) would have been in the wrong and therefore, liable. In another column we print a tentative list of signals which would undoubtedly be valuable in such cases.



Sketch of Road Intersection Where Collision Described by N. W. L. Occurred

POINTS ON FRICTION DRIVE

Editor THE AUTOMOBILE:

[2,137]—Will you please advise me through "Letters Interesting, Answered and Discussed," what is said for and against the friction drive? As I am on the point of buying a new automobile in the medium-priced class, I would like to get an opinion on this. I am more interested in durability than speed. A. SUBSCRIBER.
Crowley, La.

As for the drive, the arguments are lessened weight, lesser number of parts, simplicity, low first cost, ease of operation, and infinite number of speeds.

On the other side it is said that the friction form possesses many disadvantages, such as lack of holding power, too raipd wearing out of the friction surfaces with consequent expense and cost of frequent replacements.

The lack of holding power alone would more than counterbalance all favorable advantages could it be proven definitely. The fact that it has been impossible to prove this to the satisfaction of all concerned accounts for the continued existence and healthy growth of the companies manufacturing this form. Otherwise, they would have been obliged to go out of business long, long ago, for want of business support.

Manufacturers on this type of transmission say, also, that the frictional surfaces which wear out are very cheap in price, so that their cost is negligible, while the work of replacing them is also very small and inconsiderable.

SIGNALING CODE FOR AUTOS

Editor THE AUTOMOBILE:

[2,138]—Will you kindly tell me through "Letters Interesting, Answered and Discussed," what warning or signal I am supposed to give an automobile ahead of my car when I wish to pass such car on a public highway at night, when any body motions on my part cannot be seen by the person at the wheel of the car overtaken? It occurs to me that an established signal code blown on the horn, known to both to mean "I wish to pass you" would be practical and very useful to tourists. More than this, it would enable the overtaken car to give the allotted road to the passing car. Are there any fixed road signals to be used in such cases, and if so, what are they? READER.
Buffalo Lake, Minn.

A long article was published on this subject in THE AUTOMOBILE, but as this was some time ago, part of it will be repeated. At present there is no accepted code of road signals, although the need is freely granted by tourists. A series of signals advocated in these columns is as follows:

Auto Signaling Code.

(1) When running ahead and going to make port, or to stop,	One long and one short blast of horn, to be sounded not less than 30 yards from stopping point.
(2) When coming to a standstill, or have made port,	One short blast.
(3) Going to start ahead, or leave port,	One short blast.
(4) When standing still and going to back up,	Two short blasts.
(5) Starting ahead slow on bad roads, slippery or muddy,	Three short blasts.
(6) Going to turn to left at road crossing, to be sounded before starting to turn,	Four short blasts.
(7) Going to turn to right at road crossing,	Two short and one long blast.
(8) In passing a slower car on port side (left),	One long blast.
(9) In passing when abreast on port side.	One long and one short blast.
(10) When crossing intersecting roads, signal must be blown at least 20 yards distant from crossing,	Two long and two short blasts.
(11) Coming to forks of road, if any, cars, teams, vehicles coming in opposition use marine signal code; will turn to left; always keep on right side of roadway.	(Port) One long blast. (Starboard) Two long blasts.
(12) Calling for assistance if stalled on the road,	Five long blasts.

We give the letter and code in full above, but would make the criticism that there are three pairs of signals, which are alike, and while it would appear that there is no danger of their conflicting with each other, it would be best to have different signals for the present duplicates. So we are suggesting changing three of the above as follows:

(3) From one short to five short.

(8) From one long to three long.

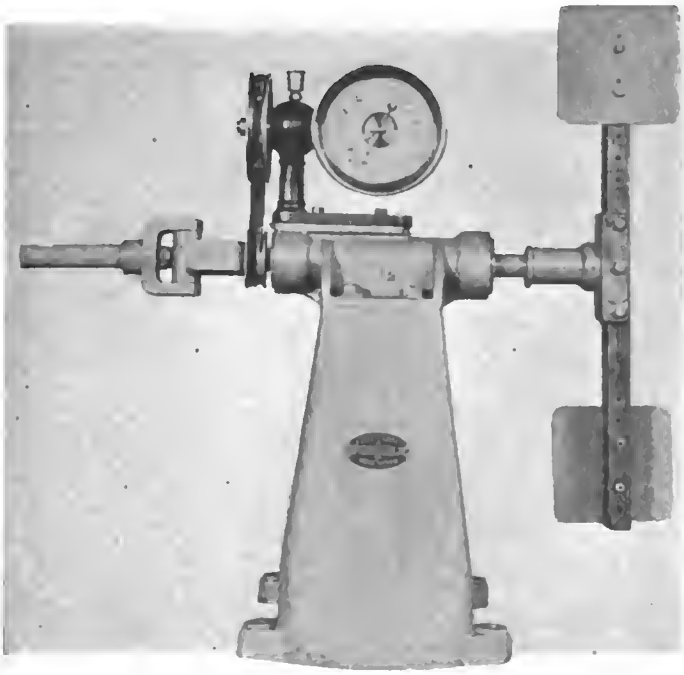
(9) From one long and one short to one short and one long, a transposition.

(11) From one long to three long or leave this as it is and change

FAN-TYPE DYNAMOMETER FOR TESTING

The standard type of fan dynamometer shown in the accompanying photograph has been placed on the market by Joseph Tracy, consulting automobile engineer, 116 West Thirty-ninth street, New York. It consists essentially of a metal standard carrying a horizontal steel shaft in large ball bearings; one end of this shaft is connected to the motor under test by a universally jointed extension shaft, the other end carries an overhung two-bladed fan, as shown. On the dynamometer shaft a small pulley fitted to a boss on the rear of the universal joint is belted to a larger pulley on the special tachometer which is mounted on top of the housing that carries the dynamometer shaft.

The tachometer is provided with a double scale and single pointer, the inner scale showing the revolutions per minute and the outer scale the horsepower developed. The r.p.m. scale is graduated progressively by divisions of 20 revolutions from 200 to 2,000 revolutions. The horsepower scale gives a minimum reading of 1 horsepower at 480 revolutions and a maximum reading of 70 horsepower at 1,980 revolutions. Consequently at all ordinary rates of motor speed a simultaneous reading of r.p.m. and horsepower can be obtained without computation.



New Dynamometer, the Invention of Joseph Tracy

This dynamometer can be employed in testing motors on the block by making suitable connection between the jointed dynamometer shaft and the motor shaft, clutch or flywheel. It can also be used to test an automobile motor in position on the chassis by disconnecting the propeller shaft and substituting for it the jointed shaft of the dynamometer.

It is designed to test motors of medium-sized cars. However, by the use of fan blades of greater or less area and suitable tachometer scales, the range of absorption and measurement of power can be varied between wide limits.

Features of this apparatus which will commend itself to builders of motors, automobile manufacturers and others include simplicity, low first cost, compactness, durability and freedom from possible breakdown or interruption of tests; ease with which readings may be obtained by unskilled help; capacity for continuous tests for long periods without constant attention.

Modifications of the standard apparatus are built to conduct tests of power delivered to the driving wheels of automobiles, either shaft or chain driven. Patents have been applied for.

SOME NEWS FROM TIREVILLE

Akron, O., Dec. 27—The Akron Auto Garage Company, joined by the Akron Auto Supply Company, gave a successful automobile show here Friday and Saturday. The festivities took the form of a celebration for A. Auble, Jr., and Fred C. Wood, who are now the Oldsmobile-Oakland agents for the state of Ohio, with a large establishment in Cleveland, established there less than six months ago. Eight years ago Mr. Auble started in the automobile business in Wadsworth, and before that he was active in the bicycle trade, and appeared in many speed contests. He came to Akron, and a few years ago was joined by Mr. Wood. They began in a modest way, but made a big success out of the agency and garage business, and since they have organized the Oldsmobile-Oakland Company they have establishments in Cleveland and Toledo, as well as in Akron, and more than 60 men are in their employ throughout the state.

Local Elks are planning to carry a greeting from "Tireville" to "Autoville" when the Elks' national convention is held at Detroit next year. A steamer is to be chartered if present plans are worked out, and some sort of a souvenir is to be designed typifying the city's advanced position as a rubber center. The purpose is to bring Akron and Detroit into close juxtaposition on account of the former being the rubber tire center of the United States and Detroit being the auto center.

AUTOS FORGING AHEAD IN THE U. K.

London, Dec. 20—A recent census shows that during the past year a great increase has taken place in the number of motor vehicles registered in the United Kingdom. The classified totals are as follows:

	Motor Cars.	Motor Cycles.	Commercial Vehicles.	Total.
England and Wales..	89,858	65,075	6,273	161,206
Scotland	7,521	5,321	421	13,263
Ireland	3,790	3,425	71	7,286
United Kingdom....	101,169	73,821	6,765	181,755

The following figures show the increase in the number of motor cabs and motor omnibuses in London during the past year:

	December, 1909.	December, 1908.	Increase.
Motor cabs........................	3,799	2,358	1,441
Motor 'buses.......................	1,164	1,115	49

A. M. C. M. A. Handbook—The official handbook of the American Motor Car Manufacturers' Association, entitled "Leading American Cars," contains detailed specifications of all 1910 models made by members of the association. It also gives the names and addresses of all members of the association.

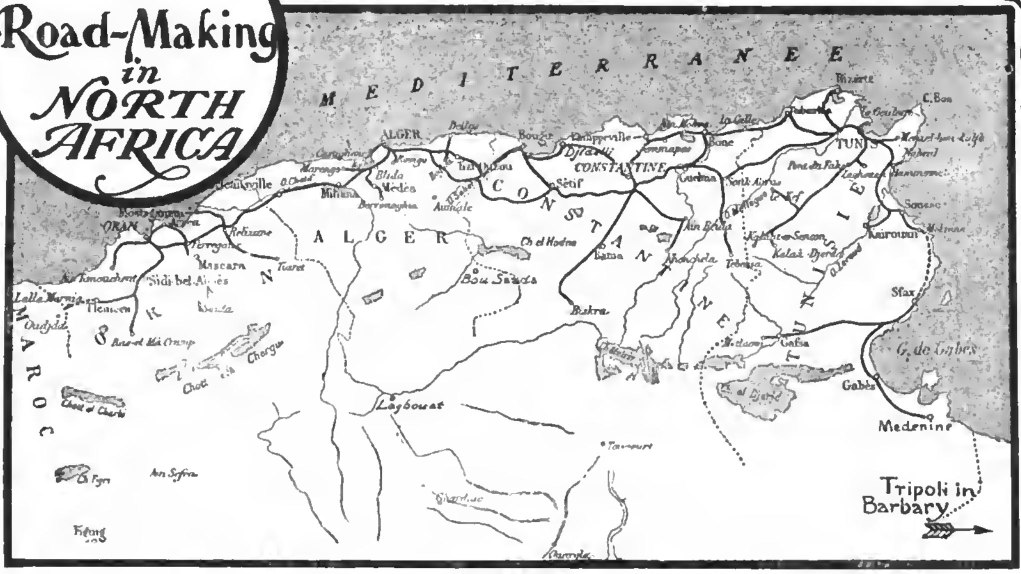
The models described have been arranged according to price classification, under the following heads: Cars up to $1,000, $1,000 to $1,499, $1,500 to $1,999, $2,000 to $2,499, $2,500 to $2,999, $3,000 to $3,999 and $4,000 and over. It is interesting to note that where 27 different models selling under $1,000, 33 models between $1,000 and $1,499, 29 between $1,500 and $1,999, 12 between $2,000 and $2,499, 29 between $2,500 and $2,999, 24 between $3,000 and $3,999 and 29 at $4,000 and over. The fact that there are 33 distinct models selling between $1,000 and $1,499 clearly shows that this is the most popular price.

In the commercial division there are 86 distinct models embracing all manner of vehicles. The prices range on commercial vehicles from $500 as a minimum to $6,000 as a maximum.

J. C. Coe, of **Saskatchewan**, dropped into Detroit recently, and by the time he had finished his errand had added nearly $100,000 to the accounts of Detroit automobile manufacturers and agents. He was not an agent himself. He told his neighbors of the far Northwest that he was going east, and thirty of them gave him their orders to be executed in Detroit. Coe paid $4,500 for his own machine and several of the others.

Roads and Road-Making in North Africa

By … FRANCIS MILTOUN



anything at all to it or back of it. Four millions of the total population of something less than five millions all told in Algeria, including also two hundred thousand Europeans, are almost entirely dependent upon the good roads of the country for their prosperity. The railway is still in embryo so far as efficient service is concerned, but the "good roads" have arrived. They are the rear arteries of the life blood of a country.

Joanne's "Algerie et Tunisie" and Michelin's "Guide d'Algerie et Tunisie," issued gratis to automobilists by the great tire house, are invaluable to the traveler. The one supplements the other immensely well, and smooths the way in many places that would otherwise seem rough. The maps in both these books are excellent. The "Carte Generale de l'Algerie," on a scale of 1-1,600,000 (which comprises Tunisie), is a large scale road map issued by the French Dépot de la Guerre, is interesting to study and have by one for reference (the cost is only one franc for the two sheets, and it may be had at the Touring Club de France), but certain modifications and new routes have in some instances been made since this map was originally issued, so it must not be trusted implicitly.

Conty's "Touriste en Algerie" gives maps of most of the roads of the Sahei and the Mitidja, the Massif of the Petit Atlas and Kabylie and of the Djurdjura, and in addition gives them in profile, showing the elevations in a most practical and interesting manner, worth much to the unknowing tourist.

The Romans built the first roads in North Africa as they did in Gaul. They built them with the labor of soldiery, helped out with the compulsory labor of land owners and tenants, as the Roman

BEFORE the conquest of Algeria by the French in 1830 there existed not a single kilometer of good road as it is known to-day, only by-paths, tracks and trails, where roamed the Bedouin and the Moor. It is a notable fact that to-day, scare three-quarters of a century later, a great trunk line, a "Route Nationale" worthy to rank with the best of those in France, parallels the coast line from the Moroccan frontier to Tunis, and sundry other side roads practically duplicate it throughout, besides a half dozen important ramifications reaching down into the desert wastes of the Sahara.

Primarily the making of these routes was a military strategy, though almost immediately they became a necessity of trade, a developer of commerce. To-day they form almost the only *reseau* of routes suitable for automobile traffic in an exotic land. The United States did her part in suppressing the Barbary pirates, but France has developed the African Mediterranean littoral in a commercial sense, and has made good roads grow where before were only camel-*pistes* and mule-tracks.

What is true of Algeria applies as well to Tunisia, though the French protectorate over that country began only a quarter of a century ago. Since that time, however, between three and four thousand kilometers of main roads have been built or relaid, and every body is happy and prosperous, though the Tunisian native is forbidden to emigrate, and the Bey himself may not *se moucher* without the permission of the French, France knew what Tunisia needed if the Bey didn't, and she proceeded to give it to the country. Result: commercial prosperity, good roads and a yearly increasing number of automobile tourists who are there seeking for new worlds to conquer.

Give a new country good roads and good railways and it is bound to prosper if there is

CÔTE de MÉDEA

EL KANTARA

legions hereabouts, according to Momsen, never numbered over 27,000 men. The plan might work well to-day, in America, for instance, where good roads are needed badly, or in Britain, where an indolent soldiery are causing untold expense of upkeep and returning very little. The procedure must have a centralized supervising power, as did that of the Romans, and county councils and petty bailiwicks, with cheap and nasty ideas of economy, should not be allowed to thrust their inefficiencies on the tax-paying public. Hitherto, in recent centuries, when local authorities have tried to build roads independent of a head supervising power, and have afterwards attempted to link them up with other short lengths, built by other self-willed beadles and bumbles, one and all have made a mess of it. This is fact and history combined. Road building is, or ought to be, considered a national work. The Romans knew and recognized this, and the French, and that is why Roman roads and French roads were and are "good roads."

IN THE GORGES OF PALESTRO

DESERT ROAD TO SIDI OKBA

OVER THE COL DE SFA

The "Itinerary of Anthony" has much to say in its folios of the roads of North Africa, and states also that where stone roads did not exist the routes of communication, trails and *pistes* were surveyed and marked with *bornes milliaires* of the same species as those which radiated from the great golden milestone of Rome itself.

Besides roads the Romans built bridges (the two go side by side), and that's why the French Département des Ponts et Chaussées handles road-making and bridge-building to-day as did the Romans and Napoleon before them.

The bridge of El Kantara, between Batna and Biskra, is the outcome of a Roman work on the same site rebuilt by the unesthetic military geniuses of 1862 in an entirely clumsy manner, though for all that it still stands a massive monumental work, albeit it has entirely lost its aspect of antiquity

The roads of Algeria are beautifully engineered. Route Nationale No. 1, at the Col de Ben Chicao, rises to a height of 1,220 meters, and the caravan route between Djelfa and Laghouat to 1,275 meters. Route No. 9, near Setif, too, rises over 1,100 meters. In spite of these elevations, all of them achieved from the lowest levels, and in comparatively short distances, the grades are seldom more than 5 per cent. (1 in 20). On route No. 3, practically at the entrance to Constantine, there is a bit of a climb of 20 per cent. (1 in 5), about all even a modern automobile can tackle comfortably.

The three following surveys indicate certain of the characteristic topographical features which one meets on a cross-country Algerian road.

ITINERARY NO. I

Towns	Altitude in meters	Kilo-meters	
Alger	...	...	
Blida	...	50	Gorges de la Chiffa.
Médea	920	90	20% côte.
Boghari	623	177	Great Arab market.
Bougzoul	658	198	Commencement of the desert mirages.
Guelt-es-Stel	920	268	Caravan serail.
Rocher-de-Sel	...	303	Salt mountain.
Djelfa	1150	331	Cold in winter.
Ain-el-Ibel	1040	368	Deep sand for some kilometers.
Laghouat	795	442	Chef-lieu of Cercle Militaire de Laghovst, 5.000 inhabitants, of which 300 Europeans. Hotel Horace.

ITINERARY NO. II

Towns	Altitude in meters	Kilo-meters	
Alger	...	...	
Maison Carrée	...	12	
L'Arba	128	30	Native market.
Col de Sakamody	741	50	Very picturesque.
Tablat	...	68	Dejuner (Auberge).
Aumale	880	124	Night stop.
Sidi-Aïssa	672	156	Tiny oasis. Road from here to Bou-Saâda has recently been put in good shape (1907) (macadamisée); one can stop here at a pinch. Hotel.
Bou-Saâda	578	248	Good for three or four days' excursion to El-Hamel; guide; small Arab at Hotel.

ITINERARY NO. III

Biskra to Touggourt via the Caravan route, 204 kilometers

Caravan pace	50 kilometers a day (4 days)
Horseback	32 hours
Diligence	24 hours
Automobile	10 hours

Following the itinerary and schedule of the camel caravans the journey works out as follows:

First day	51.6 kilometers to Chegga
Second day	52.8 kilometers to Mraier
Third day	44.6 kilometers to Ourlana
Fourth day	54.9 kilometers to Jouggourt

Hotel accommodation exists only at Mraier en route. At Chegga and Ourlana the hordj or caravanserai offers shelter only. Food and drink must be carried.

The traffic conditions of Algeria are extraordinary. At a busy corner in Algiers 6,000 *colliers* (horses, mules and donkeys) pass per day, while on certain of the highroads in remote districts the number falls to 60 *colliers.* The average on the Routes Nationales of France is 185. Algeria, then, with its limited population has proportionately a far greater traffic by road even than France. This enormous going and coming by road in Algeria (and Tunisia as well) has necessitated "good roads," and as such the roads of North Africa exist to-day. And they are well kept amid great difficulties, for excessive dryness for the greater part of the year mitigates greatly against the easy upkeep of stone ballasted roads, the *routes empierrées* or the French system of good road classification.

AN OUTPOST HOTEL at FIGUIG

In Algeria there are 3,000 kilometers of "Routes Nationales," 600 kilometers of "Routes Départementales," about 7,000 kilometers of "Chemins de Grande Communication" and another 2,000 of minor, but well-engineered and well-kept roads called "Chemins d'Interet Commun."

These roads, be it recalled, are nearly all of them lengths of modern roadway paralleling the coast. Crossroads are few, as yet, the tangents running to Bou Saâda, Biskra, Laghouat and Djelfa, being the chief of the "good roads" running across country, and the latter are only practicable for automobile traffic in their entirety under favorable conditions. The *pistes,* or caravan routes, are practically unsuited to wheeled traffic of any sort, and, of course, are not included in the figures given.

Adequate road signs are to a great extent lacking if one omits the governmental mile stones or "bornes kilometriques." In the vicinity of Algiers, and in certain other localities, the French Alpine Club has put up *poteaux indicateurs,* which render, even to automobilists, valuable services as far as they go. One of these is shown on one of the preceding pages.

From Blida ascending the wonderful Gorges de Chiffa, beyond the Ruisseau des Singes, rises the Côte de Médea. Médea is one of the celebrated centers of wine-growing in Algeria and its *crus* are of the first rank. For this reason a good road became an early necessity. The Côte de Médea is on the main road from Alger to Laghouat and is the scene of the annual hill-climb of the Automobile Club d'Algerie. It is a 6 to 10 per cent. steady rise for the most part. It rises up the mountain side in those picturesque hair-pin lacets which one usually only associates with Switzerland or Dauphiny or Savoy in France, where the roads are even more wonderfully engineered and graded than those of Switzerland, great as the latter may be or actually are.

The main road leading out from Algiers is most interesting throughout, as here and there it cleaves the plain, tunnels through a rock wall and finally climbs up to a bare, dreary height and passes through a gateway known as the Portes de Fer. It is a tangible monument to the prosperity of the neighboring country which has developed as a result of the accomplishment of this great Route Nationale.

The mountain road through Kabylie is in quite a different category, though it serves the region well enough. This road on the main is simply a strategic highroad conceived by the military authorities as a thing to be valued for the future rather than for the present alone. The mountain region of Kabylie is about the wildest through which it is possible to pass an automobile to-

ROAD THROUGH DJIDJELLI

day, though before March it is no unusual thing for it to be snowed up for days and days.

The direct road via Ménerville and Salestro is practicable throughout the Winter, though at its greatest height, even here in semi-tropical Africa, a meter or more of snow has been known to lie on the road for days, and only last season the railway itself was snow-bound for twelve hours or more. And this is Africa!

SOME TUNISIAN ROADS

From Bougie there is a remarkably picturesque road traced through via Djidjelli and Zeraia to Constantine, 257 kilometers. It is a *"corniche"* road beside the sea for nearly 100 kilometers, and from many points of view, principally that of a savage wild environment, it is the peer of that more famous "corniche" between Nice and Monte Carlo, where auto scorchers and racing electric trams have made one of the most beautiful strips of coastline in the world extremely dangerous and hideous. This road via Djidjelli is reckoned by the government authorities as a "route empierrée, en bonneétat." A daily diligence covers the same road, and all the difficulties encountered can be summed up in the few words which describe the lacets and twistings and turnings as dangerous at high speeds. Otherwise the roadway is superb.

From Setif to Constantine, *"la ville Sérienne"* of the ancients, which most of us have hitherto known only by the contemplation of Vernet's picture of its famous siege now in the gallery at Versailles, is but 127 kilometers, the road rising and falling continually, and then shooting up into the air on a 20 per cent. flight just as Constantine is reached.

The road out from Constantine to Philippeville and Bone, over the Col des Oliviers, is interesting and sufficiently dangerous in some of its rises and falls to be exciting. It is, in fact, a remarkably good piece of road building, and on it even a low-powered automobile can beat the railway between the two points every time.

From Constantine to Batna via Kronbs is 119 kilometers of quite the best long stretch of roadway to be found in North Africa. Batna is hotter than blazes in Summer and about as cold as Greenland in Winter. This is caused by the fact that it sits on a high plateau. Between seasons it is delightful as to climate.

Out from Batna on a round of 80 kilometers of dreary sun-baked, but well-built roadway lie those wonderful buried cities of the Roman occupation of the past—Timgad and Lambèse. There is nothing so grand yet discovered above or below ground, excepting Pompeii.

There is a string of these buried Roman cities running southwesterly from Tunis and they, as well as the roads connecting them, were built by Roman soldiery, with the assistance of such native labor as was available. To-day the excavations at Lambèse are being carried on with the labor of the prisoners of the great penitentiary nearby who also have been put to work on the roads, not at mere stone breaking or oakum picking, or left in solitary confinement. Here's an idea for using a vastly increasing supply of manual labor, of which there is a superabundance.

To El Kantara from Batna is 87 kilometers, the road of the plain now climbing the foothills of the Aures until it finally culminates at the rock-wall, known as the Gorge of El Kantara, literally the curtain which shuts off the desert from the sown. The pass through the gorge, the old Roman road crossing the now dismantled bridge, the modern road and the railway as well form a wonderfully picturesque and practicable combination. The route from El Kantara plunges down a 50-kilometer descent via the Col de Sfa to the edge of the desert at Biskra.

Though the road here ranks as a Route Nationale, it degenerates into a vague undefined track over the Col de Sfa. It takes up with its old form again later on. There are 10,000 camels passing this way to a hundred wheeled carriages and one automobile. When the reverse is the case—or before—the Col de Sfa will doubtless be leveled off a bit and the rough places smoothed out. At present the Col de Sfa in Algeria is a little brother to the mountain road up Mont Ventoux in Provence, a 22-kilometer hill climb up a finely graded road with a very loose surface. The Saharan track would be more nearly suited to the automobile were it not for these soft patches of sifting sand.

THREE KINDS OF TRANSPORT IN ALGERIA

In ten hours from Biskra, if all goes well, an automobile will be at Tougourt, in the very midst of the sandy ocean of the Sahara, where the Hotel de l'Oasis will be found not bad. Garage accommodation, as such, is, of course, non est, and supplies of essence and oil for the return journey will have to be carried or sent down from Biskra, the *bidons* (the regular two-gallon tins of the petroleum trade) slung together across the hump of a camel.

En route for Tunis the road doubles back from Biskra, 226 kilometers, to Kroubs, and to Bone another 180 kilometers.

From now on the road to the Tunisian frontier lies via La Calle and Tabarka, and is a long way from being a bee line; in fact, it is well-nigh 200 kilometers out of plumb. Via Souk-Ahras and Le Kef, from Kroubs, there is only a *"piste carrossable,"* unsuitable enough for automobile traffic to-day except at the expense of pneumatics and "la mecanique."

There are no topographical difficulties to be encountered on these roads of the Constantinois, the eastern province of Algeria, and they are rather more highly developed than those of Western Algeria. Habitations hereabouts are infrequent, however, and a leaky radiator, pump or petrol tank might possibly mean that an automobilist would be uncomfortably stalled if precautions were not taken beforehand.

From Bone to Tunis is nearly 300 kilometers, and, take it all in all, the itinerary is as varied a one as will be found in all North Africa, the road surface being entitled to rank as "very good," with perhaps bad spots here and there.

The roads of Tunisia are also of the same class as those of Algeria and are ranked "very good." Of this class there was in 1907 5,000 kilometers (practically all trunk lines) already open, with 200 kilometers more in the making, and still other great projects all looking to the developing of the *Sud-Tunisie*.

The roads in the environs of Tunis are almost invariably excellent. Particularly is this true of those running from Carthage and its three superimposed buried cities to Bizerte and its modern arsenal; from Nabeul and its potters to Khorbus and its baths, and from La Marsa to the great dam at Zaghouan.

Teboursouk and Dougga and their Roman remains are only a hundred kilometers away over a trunk line road, and Kairouan, the Holy Musulman city of Tunisia, with its open door mosques (all others in the country being shut against dogs of infidels) but 155 kilometers, and all of it over good surfaces.

Beyond, still towards the South and the great desert, are Sousse and Monastir, the quaintest of Mediterranean ports, and the great amphitheater of El Djem, one of the most astonishingly placed Roman monuments one ever came across, sitting close beside the modern Route Nationale the descendant of an ancient road, built here at a period contemporary with the great Roman arena. Southward another 60 odd kilometers is Sfax. From Sousse to Sfax is a great gap not yet bridged by railway. The service is kept up by automobile omnibuses. This speaks well for the roads of Tunisia, that the automobile can go where the railway has not attempted to stretch forth its streaks of iron rust.

From Sfax to Gafsa runs a cheap sort of railway, mostly used to transport phosphate from the mines, but carrying passengers as well, with considerable difficulty—to the passengers.

This automobile service between Sousse and Sfax runs in competition with the conventional stage-coach of old, the French diligence in fact, except that it is hitched up behind six mules and presided over by one swarthy Arab to hold the lines and another to do the lashing out with a rawhide, and the swearing.

The prices for the various kinds of accommodation offered are as follows. If any far Western stage company thinks of installing a similar service the figures as to what is being done here may be of some service.

First class, in automobile, 128 kilometers, 25 francs.

First class, in diligence, 128 kilometers, 12 francs.

Second class, in diligence (on the roof), 128 kilometers, 8 francs.

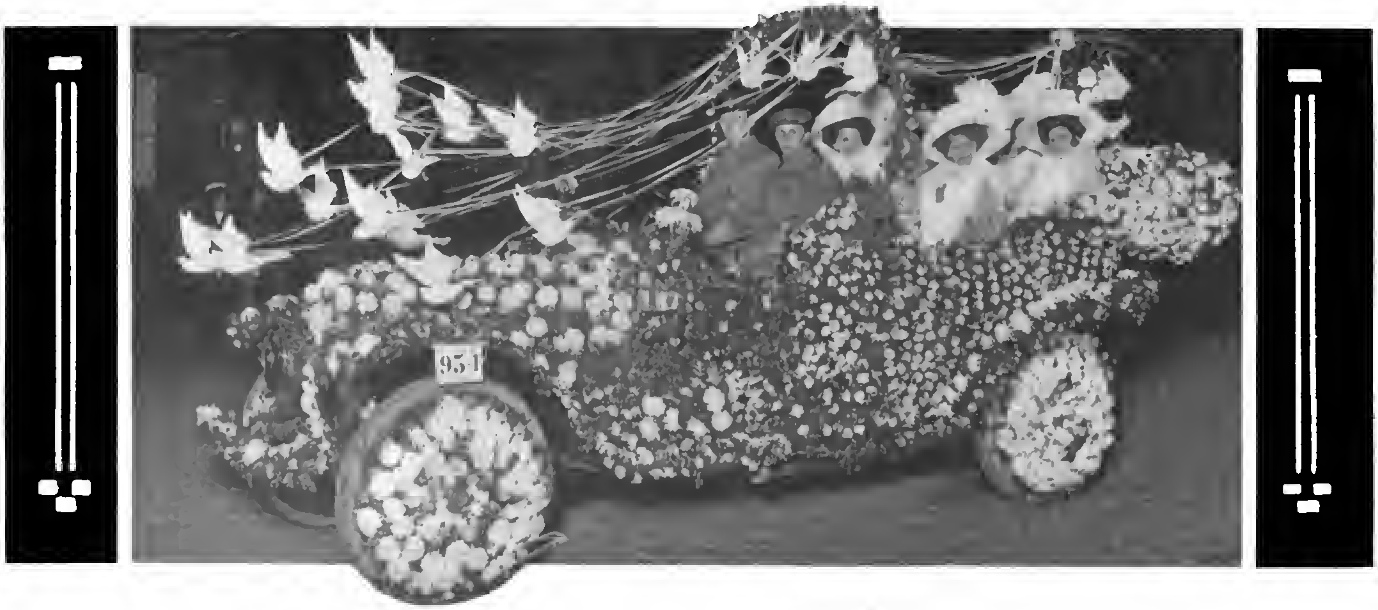
The automobile takes six hours en route and the diligence fourteen. Time is money, even in Algeria!

As far as Gabès, 405 kilometers from Tunis, the road still holds good, and to Medenine, another 75 kilometers, it is practicable, though leaving much to be desired here and there as to surface which is apt to be overblown with soft shifting sand.

Beyond Medenine, not far away now, is the frontier of Tripoli in Barbary, under the dominion of the Sultan of Turkey. Automobiles are not in favor in the realms of the Sultan, nor are there as yet roads suitable therefor, so unless one is prepared to continue their route by aeroplane this must end the automobilist's North African itinerary.

To Theater by Aeroplane—According to the English *Automotor Journal*, the management of Her Majesty's Theater, Carlisle, has placed on its programs the announcement that for the convenience of patrons coming from a distance aeroplanes can be stored free of charge.

There will be no motor car exhibition in Berlin next year, as at the general meeting of the German manufacturers and traders the motion to resume show promotion, which has been interrupted since November, 1907, was defeated.



Pierce-Arrow Car, Owned by William Bausch, with Which He Won a Rochester, N. Y., Floral Parade

Arch of Septimus Severus, Rome, with Palatine Hill on Right, and Packard with Boston Automobilists in Foreground

MANY AMERICANS ABROAD THESE DAYS

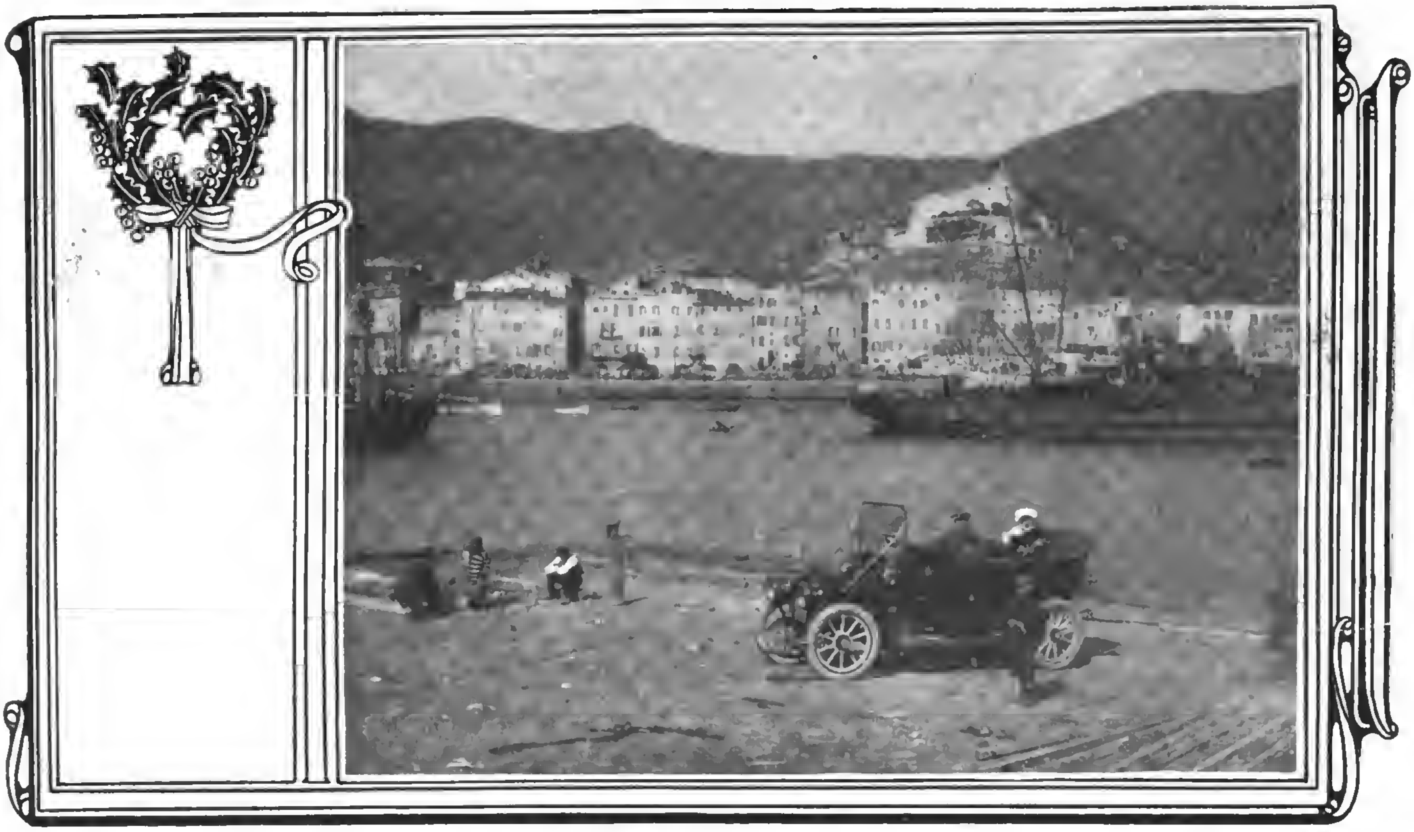
PARIS, Dec. 24—When France proposed to impose a tax on automobilists from abroad who use her fine highways she evidently did not realize that these same automobilists this year left behind them a train of gold representing, on a moderate estimate, not less than $7,200,000. "The Packard Motor Car Company alone," declared H. D. Wilson, their Paris agent, to THE AUTOMOBILE representative, "is responsible for turning $450,800 into the hands of French hotelkeepers and others. This year 250 of our cars have passed through France. They carry, on an average, six persons and remain one month. Each person spends on necessaries—ignoring such luxuries as works of art, curios, etc.—the sum of $10 a day; thus a little calculation shows the correctness of the total sum of $450,800."

But the Packard company is not the only one sending cars to Europe for touring purposes. Figures supplied by the Royal Automobile Club of Great Britain, the Touring Club of France, the Automobile Association of Great Britain, and the Association Generale Automobile, show that 2,000 triptyques have been issued to American and English automobilists this year. This, however, by no means completes the number having entered France with foreign cars, for many owners pay the customs deposit instead of taking out a triptyque; others come over with European cars on which there is no duty to be deposited; a certain number of rich Americans maintain an automobile in France and use it only on their annual trips to this country. A still larger number prefer to hire an automobile from one of the many agencies established for that purpose in Paris.

On a moderate estimate the triptyques only represent 50 per cent. of the automobiles employed by Americans and English for touring through France. The total number is certainly not less than 4,000 for the present year. The American automobilist rarely remains less than six weeks; his English cousin is content with a much shorter period, but the average stay can be taken as a month. Estimating six persons in each car, a stay of one month, and an expenditure per person of $10 per day, the amount of money left behind is $7,200,000. The automobile is directly responsible for this entire sum, for no account is taken of the hundreds of Americans who tour in the ordinary way, nor of the sums the automobilists spend on objects having no connection with touring and every-day living expenses.

The most remarkable feature of the European touring move-

Packard Tourists Opposite the Ancient Roman Forum



The Harbor Front at San Remo—Tourists Enjoying the Delightful Climate and Picturesque Features of Southern France

ment is the number of American-built cars that are annually brought over. Packard seems to be at the head of the list with its 250 for the present year. This only represents the number of cars that have been reported. A certain number of owners, having no need for spares or for touring information, arrive and return without the Paris office being aware of their presence. In addition to the complete stock of parts and the up-to-date touring information, the Paris branch now maintains a mechanic, sent direct from the factory at Detroit, and on duty during the season.

At Rear of Palace of Justice, Rome—Cavour's Statue

N. S. Goodsill, the Pierce-Arrow Motor Car Company's European representative, reports 112 cars during the first nine months of this year, and estimates that the total will be 125 to the end of December. Nearly all the cars are six-cylinder models, of 1909 production, and carry an average of five passengers. Last year there were a few bad smashes, due to inexperienced handling. During the present season the sale of spare parts has been confined to brake liners which give out on the long mountain descents with their perfect surfaces, unknown in America. Though not established for selling, the missionary work done by the visiting automobiles is so effective that the Pierce agent will be obliged to obtain an option on a certain number of cars next year.

Peerless is the third firm having a Paris spare parts and information bureau. M. Bousquet reports that the number of automobiles already reported and expected during the coming portion of the year will be from 70 to 80. These three are not the only American firms represented by tourists in Europe this season. The others, however, do not maintain offices on this side, nor are their cars seen very frequently. Among those that the writer has come across are White steamers, Locomobile, Thomas, Ranier, Maxwell, Welch, Ford, Mitchell and quite a number of other representative American makes.

The recent international agreement on the acceptance of driving licenses in countries other than of issue will doubtless have a stimulating effect on automobile touring during the coming season. Many would-be tourists have refrained from bringing over their cars on account of reports of the red tape involved in securing the necessary permits. In many cases these difficulties were exaggerated, it is true, but no one could find fault with the present regulations. A single examination, which may conveniently be taken in either France or Germany, will admit to every Continental country the tourist is likely to visit.

How Jacob's Ladder Became Climbable

By Cortlandt Field Bishop

THE extreme western part of Massachusetts consists of the region known as the Berkshire Hills. These, roughly speaking, extend north and south between the Connecticut river and the New York State line. In other words, this region comprises the broad upper valley of the Housatonic river and the mountains to the east thereof, forming the watershed between the two rivers just named. This district is hilly in character and sparsely settled, its population being far less than formerly when the now-abandoned farms were occupied.

To the east, this region is drained by the numerous branches of the Westfield river, which empties into the Connecticut not far from the city of Springfield. The route that has been adopted for the main trunkline of State highway across the commonwealth of Massachusetts, from the city of Boston toward Albany, ascends the valley of this river from Westfield, closely following the railway. At the town of Chester, some twenty-nine miles from Springfield, this highway leaves the railway and gradually ascends westward following the windings of Walker brook. Up to this point the grades have been slight and the roadway nearly all of macadam.

For thirty-three miles from Springfield there was practically no choice of routes for the tourist who wished to visit the Berkshires in his automobile. But from the crossroads known as Bonny Rigg Corners, there were two roads. The one to the north rejoins the railway at Becket Station and proceeds to Pittsfield up and down a series of short hills over wretched roads with bad surfaces. The other alternative was to proceed due west, surmount the watershed by a long steep ascent and descend less rapidly, but without crossing intermediate ridges to the Housatonic river at Lee, whence several years ago a splendid highway was built to Pittsfield. It is the last route which bears the name "Jacob's Ladder," and it is doubtful whether there is any stretch of road in the New England States which has caused more trouble to automobiles and their owners.

Starting from Bonny Rigg Four Corners, the ascent rapidly became greater, the road surface poorer and poorer, until, as one emerged from a wooded tract, there appeared right ahead an almost perpendicular stretch which seemed to reach to the heavens. Some years ago there was at the base of the "Ladder" itself a spot on which for many years, before the advent of the automobile, the roadmakers had utilized as material for repairs the refuse sawdust from an old mill. This place was known far and wide as "Sawdust Hole," and few were the automobiles that could get through it. When dry it was hard enough, but the intelligent farmers in the region discovered that sawdust mixed with a little water would stop any automobile, no matter what its power. Consequently, they made a practice of adding a little sawdust whenever rain fell and water when it did not. As a result, the autoists, after vain efforts to extricate their cars, were forced to go back to the nearest house for horses, and the regular schedule price for their use was based upon the horsepower of the stranded car. "Sawdust Hole" was put out of business five or six years ago as a result of the expenditure of a fund raised by some of the automobile owners of Lenox.

But "Jacob's Ladder" remained, and it was not till October, 1909, that the old road over the crest of the watershed was abandoned. The writer has been familiar with "Jacob's Ladder," or Morey Hill as it used to be called, for more than twenty years, and he can well imagine with what feelings the autoist who had emerged from his struggles with "Sawdust Hole" beheld it for the first time reaching far up above him. The road surface was never good—it was always rough and narrow, and there were two or three spring holes near the top which were fatal in wet weather. The farmer in the nearest house kept his horses ready, and few were the automobilists who did not contribute to his daily income. In some spots the grade amounted to nearly 20 per cent.

Jacob's Ladder as It Once Was

All is now changed. "Jacob's Ladder" is a thing of the past, and as a result of a campaign which has been carried on vigorously for five or six years, the watershed between the Housatonic and Connecticut valleys is crossed by a wide, well-built macadam road, whose grade nowhere reaches 7 per cent. It has required the combined and persistent efforts of many persons and many interests, but in the Winter of 1908 a special appropriation of $50,000 was secured from the Massachusetts Legislature for the improvement of this stretch of highway.

The most important part of the work done under this appropriation begins at the foot of the final ascent, and at a point one mile west of "Sawdust Hole" the new road leaves the old

Road In Process of Construction

location and curves off to the left in a wide sweep, and reaches the watershed at a point a quarter of a mile south of the former summit and nearly two hundred feet lower. It then bends to the northwest and descends with a gradient of about 6 per cent., rejoining the old road at the foot of the hill, the total length of the new layout being about 6,800 feet.

In addition to this "Jacob's Ladder" proper, a strip of two miles of macadam, covering the former "Sawdust Hole" and the approaches from the east, was built under this appropriation, and it was opened to travel in October of this year. Not only the road itself is of a permanent character, but bridges and culverts of armored concrete have been built, and concrete parapets and wooden guard rails provided where necessary.

In 1909, a sum of $25,000 was secured for the purpose of improving the highway from "Jacob's Ladder" westward toward the town of Lee. With this money, a stretch of four miles of bad and narrow road has been entirely rebuilt, drained, and graded. In several places the road has been relocated and steep pitches avoided or reduced. Substantial concrete bridges have been built, but no macadam laid. The narrow road along the north shore of Greenwater pond has been widened and raised above the highwater mark.

As a result of the work of these last two years, there remain only a few miles of unimproved road in this main trunkline of highway which extends across the commonwealth of Massachusetts from Boston to the New York State line, there to join the main road which will soon run through to Buffalo. There remain about two miles in the eastern part of the township of Chester and about five miles in the towns of Becket and Lee which are still unimproved. It is to be hoped that the combined influence of those who own automobiles in Massachusetts, and allied interests, will be brought to bear upon their representatives in the Legislature in order that at the session which opens on January 1, sufficient money may be appropriated to complete the work so well done in 1908 and 1909. No finer ride may be imagined than that which is now accessible from Springfield to Pittsfield across the once dreaded "Jacob's Ladder."

Completed Road Around the Ladder.

ON GOOD ROADS

From the report of the Committee on Good Roads at the Annual meeting of the Carriage Builders' National Association, at Washington, D. C., the following interesting excerpts are taken:

"Better roads are one of the pressing needs of the United States. In the innumerable things that have had to be done to put the country in the commercial, industrial and social position it has achieved in such a marvelously short time, road building until very recently has largely been overlooked, and the important place occupied by highways in the expansion of a nation might not even yet have been so generally recognized if it had not been for the advent of the bicycle and the automobile.

"Within the last decade not only the drivers of vehicles have come to want good roads, but the people and the interests which will financially profit by them have awakened to what they are losing by poor highways.

"When the means of communication are bad, people are disinclined to venture far from home, and social and business relations are narrower in the country districts. Many a farmer curtails his crop simply because he has no way to market them.

"The railroads have come to realize that they are losing hauls that they might have if the agricultural districts remote from the large cities had good roads over which to get their produce to the cars.

"Some of the railroads of Virginia, for example, have taken hold of the question in a practical way. Virginia is entering upon an era of road building; to help open the State, as it were, certain railroads have made a proposition to carry all material for road building at cost, and all laborers and machinery intended for the work free. Much will be saved in this manner that can be devoted to road building, and the railroads will reap a return in increased freight traffic."

FRENCH AVIATORS DEVELOP NEW POSSIBILITIES

PARIS, Dec. 24—Count de Lesseps, son of the French engineer who dug the Suez Canal, has set up a new record for the Issy-les Moulineaux ground and the Blériot cross-Channel type of aeroplane. After a short apprenticeship, the aviator succeeded in remaining aloft 1 hour and 30 minutes. Although all the early flights were made on the Issy ground, no aviator has attempted to make an endurance flight at this place. The performance is also a record for this type of machine, the previous longest flight being performed by M. Blériot, and not exceeding 45 minutes.

In his intervals of teaching Lee Guinness, the British millionaire brewer, famed for his ownership of the Darracq eight-cylinder record-breaking automobile, Hubert Latham is flying over the Mourmelon plain with various loads on his Antoinette. His latest exploit is to carry a cinematograph operator together with all his equipment. The flight, which was of about eight minutes' duration, was made at a height of fifty feet, the operator turning the film through the machine all the time while in the air. The supplementary weight was about 250 pounds, of which the operator was responsible for 140. This is the first time moving pictures have been taken from a flying machine, but not the first time photographs have been obtained. When Latham attempted to cross the English Channel last Summer he had a kodak fitted up in the bow of his aeroplane. Exposures were made with it, but owing to landing in the water everything was destroyed.

Louis Paulhan, who, after considerable hesitation, has decided to desert his native land for a few months in America, has just completed his apprenticeship on a Blériot monoplane. He can now fly on three different kinds of aeroplanes: Voisin and Farman biplanes, and the Blériot monoplane. The first two mentioned are so similar that a man who has mastered one ought to be at home on the other. The Blériot, however, is of such a different type that it is surprising Paulhan should have been able to fly with it on the first attempt. The French pilot appears to have been afraid of legal trouble with the Wright Company if he came to America, and in order to prevent the seizing of his machine he has removed the ailerons from the Farman and the wing-warping mechanism from the Blériot. The Voisin did not need changing, for the Wrights have never claimed that it infringed.

Jacques de Lesseps, in Costume

SMALL SANTOS MACHINE IS POPULAR

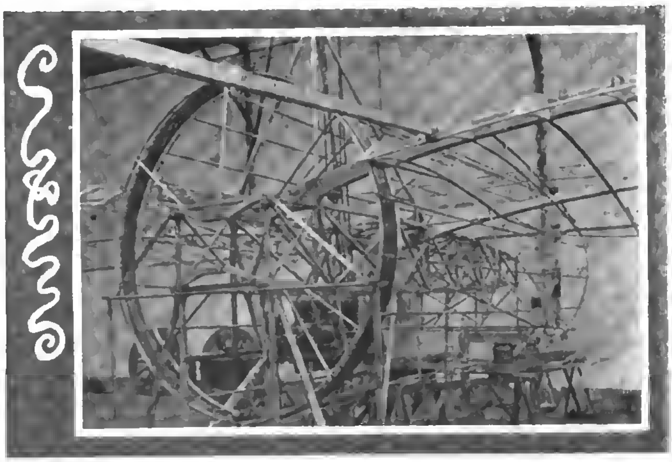
PARIS, Dec. 23—Since Santos-Dumont met with success in flying his "Demoiselle" aeroplane there have been a number of persons who have endeavored to construct a similar machine on the model offered to the public by the young Brazilian. The latest and most interesting of these copies is one produced by M. Nieuport, of magneto fame, who although following the general Santos-Dumont design, has introduced a number of interesting improvements. Instead of placing the seat entirely below the wings, Nieuport has built a kind of cockpit in the centre, the base of it being partly below the wing surface and the upper portion only slightly projecting. The tubular radiator, instead of being placed under the wings, as on the original "Demoiselle," is carried on each side of the cockpit.

The motor, the new two-cylinder opposed built by Darracq, is placed in front of the pilot and slightly below the front edge of the wings. It drives a two-bladed wooden propeller built by Chauvière. Instead of bamboo, steel tubing is used almost entirely for the framework of the machine. Starting is made on two pneumatic tired wheels set very far apart, while landing is performed on skids. Hayden Sands, the first American to learn to fly an Antoniette aeroplane, left Paris this week for Egypt in order to give flying exhibitions. Mr. Sands will take part in the meeting at Heliopolis, near Cairo, next February, and later will visit India and continue a trip around the world. The machine which he will employ is the one with which Latham, his instructor, made his record height flight and flew across country in order to keep an appointment with Marquis de Polignac.

Arthur Duray, who has figured in all European automobile races, and drove for De Dietrich in some of the Vanderbilt events, is now taking lessons on a Farman biplane and intends to compete in the Egyptian aero meet next February.

WRIGHTS TO USE DAYTON AUTO FACTORY

Dayton, O., Dec. 27—The recently incorporated million-dollar Wright Company, which is supported by such financiers as Cornelius Vanderbilt, August Belmont, Howard Gould, Robert J. Collier, Andrew Freedman, Morton S. Plant, E. J. Berwin, T. P. Shonts, Allan A. Ryan and Russell A. Alger, will build its aeroplanes in the factory of the Speedwell Motor Car Company, in this city. The Speedwell Company is not sacrificing any of its present manufacturing space for the aeronautical work, but is adding a new building of 8,700 square feet for the use of the Wrights. This building will be ready for occupancy some time in January, and will have a capacity of about four machines a week. It is stated that the company has already 175 orders, and they continue to come in so rapidly that manufacturing must be pushed at utmost speed to catch up.



Framework of Bertrand Monoplane with Cylindrical Body

LOS ANGELES MEET MAY BE ADJUSTED

At the meeting of the Aero Club of America to be held Thursday the final decision will be made concerning the sanction for the aeronautical meet of the Los Angeles Aero Club. The national body objects to the conditions for the prizes offered, saying that $20,000 of the prize money cannot possibly be won. There is an offer of $10,000 for a dirigible flight from Los Angeles to San Francisco, and another $10,000 for a balloon trip to the Atlantic, both feats regarded as physical impossibilities. President Bishop, however, believes that the matter can be adjusted and the sanction granted.

DETROIT WILL PRODUCE 60 PER CENT. OF ALL CARS MADE

By LEN G. SHAW

DETROIT, Dec. 28.—Now that the official statisticians have busied themselves with pencil and paper and solemnly aver that the year 1910 will witness the production of approximately 200,000 motor cars, it is interesting to note what part the hub of the automobile industry is planning on playing in these proceedings, and what it will probably accomplish.

There are twenty-four full-fledged automobile companies in Detroit, in addition to which are several who have not yet cast aside their swaddling clothes. Five of these concerns will write their output of cars in five figures, and at least four others will reach the five thousand mark or better before the end of a season that is already well on its way. All the others will produce automobiles at a rate that, now considered very commonplace, two years ago would have placed them among the leaders.

Forecasting a season's output and living up to the forecast are two vastly different things, as many a factory manager can testify to his sorrow. This statement is particularly applicable at a time like the present, when difficulty in securing parts and even raw materials is a factor that must be reckoned with. According to factory managers, who speak advisedly, and whose determination is to live up to their predictions, Detroit will during the present season give the country no less than 120,00 automobiles. That means that if their expectations are realized this city will produce sixty per cent. of all the cars it is figured will be made in the United States this season. But the best laid plans of factory managers, like those of mice and mere men, oft go wrong.

If the marvelous building operations now in progress are concluded in time, and if parts and raw materials can be secured in the desired quantities, and if skilled labor is always available, and if there are no delays in the matter of transportation facilities, and if the sales departments busy themselves sufficiently, there is no reason why Detroit's automobile factories should not produce the number of cars now being planned. However, on those "ifs" hinges much, and those in close touch with the situation, and accustomed to discounting such matters, agree that if local makers produce 100,000 cars they will be going some. Even if that figure is not reached, and the output drops to 90,000, a point that is regarded as very conservative, there will be no occasion to be ashamed of the showing, as that will still be 8,000 in excess of the actual output of cars in the entire country in 1909.

First and foremost, of course, in the matter of numbers come the E-M-F interests, who, seeing a favorable disposition of their disagreement with the Studebaker Automobile Company, are laying plans to build 25,000 Flanders Twenties and 15,000 E-M-F Thirties. Close behind comes the Ford, with 21,746, others who require five figures to tell the tale being the Cadillac and the Brush, with 10,000 each to their credit in the forecast. The Hupmobile proposes building 7,500; Chalmers-Detroit, 5,200; Hudson, 5,000; Regal, 5,500; Packard, 3,000; Everitt Thirty, 2,500; Demot, 3,000; Krit, 1,000; Abbott, 1,000; Warren, 1,000; Owen, 500; Welch-Detroit, 500; Detroit-Dearborn, 500; Herreshoff, 1,500; Detroit electric, 1,500; Anhut, 750; Paige-Detroit, 3,000; Van Dyke, 3,000; Grabowsky, 300.

Of course, many of these figures are predictions, founded on good faith, but entirely dependent upon conditions that may arise. The older concerns will all be able to make good, in spite of the great increase over that of last season. They have been through the mill. Some of the younger ones will experience difficulty in living up to expectations that would terrify those older in the game. Nevertheless, it is absolutely certain that if the aggregate output of the country is 200,000 automobiles, Detroit will come very near to producing fifty per cent. of these, if, indeed, it does not furnish the majority, this assertion being made after liberally discounting the plans of all local makers save those who are in a position to absolutely live up to predictions. At all events, the man who wants a Detroit built car need experience little uneasiness through fear that his wish cannot be gratified, provided, of course, he has the purchase price.

PARIS, Dec. 20.—Sport of all kinds demands special costumes if one would be well and comfortably clothed. Just as the automobile brought about, at first, leather and then fur clothing, those who go up into the air in balloons and aeroplanes have found that something especially warm and wind and chill resisting is required.

The designs herewith are no phantasies; each has been tried recently by French aeronauts and not found wanting, though perhaps susceptible of some modification. Certainly they are not graceful nor even becoming, but one thinks they are quite suitable to voyaging through first a strata of half-frozen cloud, then a sheet of rain and finally a band of crisp, zero atmosphere or less, and all these things are the aeronaut's destiny once he rises up from Mother Earth.

The particular costume herewith was of impermeable camel's hair like the waterproof "loden" of the mountaineers. It is extremely light, fairly supple and graciously warm, each and all desirable qualities. The garments are so made that with a cap, or *casque,* for the head two pieces cover one from forehead to feet, including the hands and even the feet; thus preventing currents of air from circling around the ankles. The automobilist himself would appreciate this.

Another material recently tried, lighter even than the foregoing, is paper. As M. Maire, the librarian of the Sorbonne, puts it, the Japanese have long known the use and value of paper for articles of clothing, while we ignore the fact that a penny paper quadrupled and laid across the chest has many times the value, as a heat preservative, of the best woolen tricot ever knitted by hand or machine.

It is up to the aeronauts and aviaters to popularize vests and plastrons of paper, and then, when we can buy them anywhere along the road, will spring up a new and important traffic in the product and industry which will bring millions to somebody.

Another aviater's costume has just been launched on the market, made of *Kapok* or the *duvet* of Java, a species of vegetable fiber, a poor grade of cotton perhaps, which, in the form of a lightly padded suit, is at once light, warm and waterproof.

M. Painlevé, member of the Institute of France, who accompanied Wilbur Wright in his prize-winning flight at Le Mans recently, when he gained half a million francs, stated that in little more than an hour he was nearly frozen stiff. What he meant, perhaps, was that he was cramped, but a combination of inactivity and being continually in a stiff breeze without the least shelter gave a sense of freezing because of lack of circulation. This would have been greatly allayed had some species of wind- and cold-resisting clothing been adopted, and so comes the special tailor for aeronauts. Fifth avenue tailors, get busy!

From Buffalo, N. Y., comes a report that Dr. Charles Meyers made a three-quarter mile flight in a machine of his own construction at a height of 10 feet. The trial was not public.

THE DIARY OF AN UP-TO-DATE MAN

INDIANAPOLIS, Dec. 27—Some people think it costs a lot of money to be thoroughly well groomed and up-to-date, but Charles Pinkham Jones keeps a diary that includes an expense account with a glimpse of which your correspondent was favored the other day, and from it he is able to give exact figures as to what it costs a bachelor, who uses modern labor-saving appliances instead of a valet, to present himself every morning at the bank, the perfect pattern of a well-groomed man. Here is the record for an average morning:

	Electric current K.W. Hours.
Rose at 7 o'clock and took an electric bath, for which the current used was	.3333
Heated bedroom for ½ hour with electric stove	.5000
Heated water for shaving on electric stove	.0333
Used electric boot cleaner	.0133
Pressed trousers with electric iron	.0400
Ironed silk hat with electric ironer	.0333
Kneaded dough for a loaf of bread with electric kneader	.0066
Boiled a pint of coffee on electric stove	.0666
Cooked a chop by electricity	.0666
Aired my room with electric fan	.0238
Turned on electric piano while I ate my breakfast	.0500
Cleaned the knives and forks with electric cleaner	.0010
Polished the plates with electric polisher	.0050
Curled my moustache with electric curling iron	.0025
Lighted a cigar with electric lighter	.0003
Rode in electric elevator to the basement	.0033
Drove my Waverley Electric 4½ miles to the bank	1.0000
Total kilowatt-hours	2.1789

for which I pay 10 cents per hour or 22 cents in all. This does not take account of the current used in my electric clock, but as a single K.W. hour will keep that running for ten years it seems safe to disregard the clock.

After this who will question the economy of electric power?

For the information of any reader who does not understand the term we will add that the kilowatt hour is the unit of measuring electric current charged for by the lighting company. It means the use of a thousand watts of electricity, or the equivalent of one and one-third horsepower, for one hour.

LOUISVILLE WILL HAVE BOULEVARD

LOUISVILLE, KY., Dec. 27—Louisville is to have a boulevard which will encircle the entire city. It will be constructed in such a manner as to connect all the parks beginning at Cherokee park, and taking in Iroquois and Shawnee parks, thence running northward along the river front to Portland and back over the city streets to the Highlands and Cherokee park. The estimated cost of the boulevard will be $189,000. Part of the right of way has already been secured, and, it is believed, there will be little difficulty in securing the remainder. The boulevard has been considered at great length in the past but owing to the cost it has been laid over from time to time. The Louisville Automobile Club have taken the matter up and will push the project until the work is finished.

Pioneer Autoist, Now a Londoner, Sends Greeting

How I Made My Car Pay For Itself

By Ernest Cawcroft

THE discussion of a subject of this nature marks a radical departure in the development of automobile literature. Seldom has an automobile been deemed an asset except when in the possession of the trustee of the bankrupt's estate reduced to cash in readiness for division between the owner's creditors; rather has it been regarded as a distinct liability. A man buys a house to stop paying rent to the other fellow; he buys an automobile and his payments to the other fellow are just beginning. Hence, it is obvious that in a dollar-discussion of the automobile the question must turn upon the profits of the machine as figured not only in money but in health preserved and in pleasures gained.

But the improvement in the mechanism of automobiles, coupled with the marked movement of middle-class Americans to utilize the car as a means of concentrating the expense of their family pleasures, forces a consideration of the subject in this latter-day light.

The nature of this article forces as well as excuses a few personal remarks. I am a lawyer and the owner of a Maxwell runabout of the 1909 design. If I magnify the importance of the assembled mechanism by referring to it as an automobile in the feminine gender, "she" has not paid for herself; but if I call it a machine and consider it in the neuter, "it" has paid for itself. I am going to consider it in the latter gender because my knowledge of the expense of the feminine gender is confined to bringing suits in which the wife never was to blame and the husband always named as the defendant. Nor is there a possibility of that knowledge being increased in view of the fact that a runabout will not carry a chauffeur; and, unlike the two-horsed rig of the rural swains, it takes both arms "to steer the thing." One commercial advantage of the runabout is that there is no place to seat a chaperon unless you go to the expense of putting an additional seat on the tool box. Hence I am going to tell you how my machine has "paid for itself."

Commerce is an exchange of equivalents; and surely there has been no greater commercial development in our age than the creation and exchange of an automobile for the cash of the purchaser. I gave six hundred dollars to the makers for my machine, but it has given me stimulated vigor, including increased lung power (surely a legal asset comparable with a knowledge of Blackstone), and a tendency to recreative sociability which neither I, nor the manufacturers, possess as a sale product. In other words, the running of the machine has given me more than six hundred dollars worth of stored vigor and concentrated health. I need not show that my physician's bills were so much less this season than last year to demonstrate the truth of this conclusion; I feel it in my bones, and until a man does feel his health resident within himself, until he knows as a man that he is healthy without waiting for the physician's certificate to enable him to draw his accumulated lodge benefits, he has not gained that surplus of vigor which the machine is designed to assure. Determined by ordinary business methods, can there be any doubt of the fact that my machine has paid for itself when I tell you that it has increased my capacity for decisive work, added to my ability to get a definite thing done with a resolute concentration of purpose? A machine which serves to thrill the physical man; a machine which keeps his head and feet warm at the same time, and from within his own body, no matter how strenuous his mental exertion, has paid for itself, even if the debit and credit sides of the automobile ledger do not balance.

May I ask you to bear in mind that I am a country lawyer living in the Empire State's provincial interior, subject both to the limitations and liberties of my environment. I have been in the habit of forsaking my office for a month of each year for the purpose of satisfying the spirit of the Wanderlust by roaming anywhere from Glasgow to the Panama canal, or northerly to Edmonton under the shadow of Canada's Arctic sunlight but I could not practice law at either of those points and my business suffered during the month of my absence. Then since the time came that I had wandered enough to answer in my own mind Ruskin's question apropos travel: "What is it after you get there?" I had been looking around for a mechanism which would satisfy my daily demand for a change of scene without sacrificing my permanent post-office address. I found that mechanism in my Maxwell, and now I am on the job in my office every morning exchanging honest legal advice for real money, while enjoying my vacation every day after banking hours. The automobile certainly is a good business proposition, to use the vernacular of the commercial traveller.

But my machine and your automobile are destined to be a greater source of profit with the passing of the years. In other words, the machine is going to pay for itself over again. The use of the machine is tending, and is destined to effectively modify, the mercantile system of America and the social habits of Yankee business and professional men. Returning travelers have long regarded as a subject for admiring comment the habit of British business and professional men of leaving their shops at 4 o'clock for a brief evening excursion. To be sure, this habit is due somewhat to what zealous Americans, for want of a better term or epithet, regard as British stolidity; but it is coupled with the English conviction that wealth without health is not worth the task, and that it is the duty of every English man to take daily advantage of those social opportunities afforded by a compact population located in a country of such small area, contiguous to two sea coasts. These are the causes which have induced early closing in England; this is the situation which enabled the writer to observe English business men playing tennis on Oxford green at 10 o'clock one July evening; and this is the combined social and recreative system which must be inaugurated in this country lest the vitality of our substantial families be sapped. But what will induce it but the automobile? And can we expect it to arrive, as a national habit, unless it is stimulated by the knowledge that it is a source of profit?

The fact should not be overlooked that American professional men have remained in their offices beyond reasonable hours because they had no means of going to a definite place for recreation. Population is widely distributed in interior America and sociability without companionship is futile; but the automobile has eliminated the twenty miles which intervene say between a law office and a lake resort; and the possibility of earning the gasoline during the day's work, and then of having a daily vacation without sacrificing the business of the month, are the forerunners of the coming of the English system of persistent recreative vacations. The automobile, unlike the Pullman car, means some play every day, and a business man with that advantage is going to return to his day's work with a stream of warm blood running to his head, which is the nursery of commercial ideas. This is just where my machine and your automobile have been made to pay for themselves.

While I have not deemed it necessary to tie the text of this discussion to the dollar mark, I am convinced that I have made my car pay for itself in cash in part. The calculation becomes a matter of time saved and money earned. During the three years which have elapsed since my admission to the bar of New York State, I have been impressed with the unwillingness or inability of the rural law offices to keep pace with the evolution of modern business. There is a duplication of offices and of the 194 volumes which constitute the New York reports, sometimes there is an excuseable duplication of stenographers, but then every office needs its decorations in addition to a picture of Daniel Webster, and in any event something must be done to retain the interest of the law clerk in the work of the office. But in the midst of this unwillingness and duplication it occurred to me that it was time to abolish as many "whereases" and "aforesaids" as is possible in the practice of the profession and to put the office machinery on "high gear." And my machine has tended to pay for itself in that it has accelerated the coming of that day. I had noticed that the young physician was using the auto as a right-hand assistant and I had been pained to wait in police court while my clients were brought in by gasoline machinery, and then it occurred to me that some machinery other than a Smith Premier and a telephone should be attached to a young lawyer's office; and so I bought my Maxwell in the conviction that I could make the car pay for itself.

A concrete demonstration of the truth of the latter conclusion was afforded during the first week that I operated the car. The whole transaction was a matter of machinery. I arrived at my office in the morning and the telegraph machine brought me a message stating that the attorney-general in Albany wanted me on the long distance telephone machine at 10 o'clock. I learned that he desired to enter suit for a penalty against a farmer for violating the pure milk act, and he wanted the action brought with some speed plus. I dictated the complaint to a typewriter, and that Saturday afternoon at 2 o'clock the law student and I started for a jaunt over the hills of Chautaqua county to serve the papers on the defendant. We moved along the shores of Lake Chautaqua, and over the historic French portage to the shores of Lake Erie, where we found the defendant amidst his grape vines. Returning from our thirty miles we came down the other side of Lake Chautaqua just to tip off a farmer that he "must either pay or be sued," and we collected sufficient money on the spot to warrant the taking of a fee large enough to pay for the next week's gasoline and cylinder oil. But the real point of this paragraph may be summarized by calling attention to the fact that the suit was brought in quicker time than the anxious attorney-general may have anticipated, and this did not disturb the enjoyment of our Saturday afternoon outing.

The utility of the automobile should be viewed as a time-saver and money-maker. I could never make any money out of my clients by advising them over the telephone; but I can induce them to pay my fees when I "meet them face to face," to use the touching words of the Methodist hymnal. And, right there, my car has earned many a dollar for itself. Letters sent out on the rural delivery lines have seldom induced farmers to pay, because the dishonest ones believed that no lawyer would stake the constable to a horse and carriage to make the trip over poor roads to serve a summons on a person of doubtful responsibility; while the honest ones always had the excuse during August that they could not call until the crops were in, and the pretext during January that no bills could be settled until the taxes were paid. But when the law student journeyed to their respective habitants in the machine, it was a question of pay, or offer a well-grounded excuse. Needless to say, a student with my car and his gall never failed to collect.

This brings me to the point that the supreme need of a young lawyer is to "get next" to his client. The automobile just meets this situation; it may be used with propriety to run to the country districts where the dying woman wants to make her last will and testament, and in a variety of real estate transactions it has proved to be of service in going to the spot, determining the vexing boundaries, and returning with speed to complete the legal papers. It is needless to amplify the fact that the machine may be utilized in a variety of ways in obviating those delays which have prevented the profession from keeping pace with the money-earning development of the modern business man. This implies time saved and money earned; and these are the elements which make a car pay for itself.

Need I say in passing that there is a money value in using the car to "know" one's own habitat. Increasing acquaintance follows, as a matter of course; but it is well to keep in touch with the situation in the rural districts surrounding a small-sized city. This matter of personal contact, this problem of getting knowledge of the situation based on the earth, is overlooked by those professional men who do not dabble in politics enough to keep them in touch with the passengers on "the gravel train." But the inability to judge the local situation from the fourth floor of an office building, and the remedy for that incapacity provided by the automobile, has been impressed upon my mind of late. Long before I either wanted, or perceived, the professional utility of a car, I had prepared a variety of briefs advocating the improvement of the main highways of the county and state. These briefs were predicated on the bad condition of the highways hereabouts, and, while I have nothing to say in defense of those same roads in the light of later knowledge, I am willing to admit that the highways then in mind have been found to be in better condition than anticipated. Certainly a student of the conditions surrounding the city in which he lives and an observer of the situation in those rural sections which give life to the business in which he is engaged, can get his money out of his car by using it for "a rubber-neck wagon" through the hay and grape lands of Chautauqua County.

And now it is 4 o'clock of a bright Sunday afternoon. I have worked for three hours giving form to this narrative, and as I am about to substitute the "clickety-click-click" of my typewriter for the "honk, honk" of my car, why can you wonder that I am convinced that I have made my machine pay for itself?

NEWS FROM GARAGES IN MANY CITIES

New Haven, Conn.—A garage and repair shop has been opened at Commerce and Temple streets by the Wheeler & Wuestefeld Company. A turntable, automobile elevator, a modern locker system, up-to-date wash stands and repair pits, waiting rooms for chauffeurs and patrons and an extensive repair shop are a few of the advantages. Entrances on both Temple and Commerce streets do away with any necessity of turning around or backing inside the garage.

Amsterdam, N. Y.—Green & Warnick will occupy their new garage about April 1. The building is to be 75 by 85 feet, two stories in height and of fireproof construction. The first floor will contain the office and stock room and storage space for about 30 cars. The second floor will be partly occupied by a large repair shop, with room for storing 30 or 40 additional cars.

Holyoke, Mass.—The Magna Automobile Company has moved into its new two-story building at the corner of Division and Railroad streets. The company has good facilities for handling both local and transient automobilists. A large machine and repair shop is maintained in the basement.

Mishawaka, Ind.—John L. Wilklow, a former liveryman of this city, intends to have an up-to-date garage soon. He has begun the erection of a two-story building on his property adjoining the new Mishawaka Hotel. The building will be of brick, 100 by 20 feet.

Pittsburg—The Pittsburgh Automobile Company has leased a plot 40 by 100 feet on Baum Street, near Beatty, East End, and is having plans prepared for a three-story fireproof garage. The company's present location is at Seventh Avenue and Grant Boulevard.

St. Catharines, Ont.—The Reo Garage, of this city, has originated a new storage scheme. Cars sent to be overhauled will be stored during the winter if desired, and no charge will be made except for work done and the repair parts at list prices.

Cincinnati—Work is nearly finished on the new garage of the Jungclass Automobile Company at Reading road and Maple avenue, Avondale, and it is expected that it will be ready for occupancy this week.

Cartercar an Awful Hard Puller, Outpulls Traction Engine

George Reason, branch manager for the Cartercar Company of Detroit, says that he is not afraid to hitch the Cartercar to anything, because of the steady pull the car exerts through its friction transmission and chain-in-oil drive, and that this is possible because of the unlimited number of speeds on a Cartercar.

Premier in Vaudeville—To help Santa Claus in bis annual labors, five vaudeville performers at one of the Indianapolis theaters started giving entertainments in the hotels, clubs and restaurants before and after theater hours, assisting the fund raised by a local newspaper. However, they found it no small task to visit all the places afoot. When H. O. Smith, of the Premier Company, heard of this he tendered the use of one of the company's automobiles, and from that moment the vaudevillians became familiar sights in the streets of Indianapolis. They raised more than $500 for the fund, and as a result hundreds of little shavers found that old man Santa had jammed their stockings full on Christmas morning, much to their delight.

Omaha Dealers' Meeting—At a meeting of the Omaha, Neb., Automobile Show Association, held last week, the following officers were elected: J. J. Deright, president; J. T. Stewart, vice-president, and C. G. Powell, secretary and treasurer. The officers, with Willard Hosford and T. R. Kimball, constitute the board of directors. There are at present 20 members of the association, and as many more applications for membership on file, so great has been the growth of the trade in this city. The show this year will be held in the Auditorium under the management of Messrs. Powell and Hosford.

Hoblitt Is Promoted—Fred M. Hoblitt, who will be remembered by future generations as the hero of the horse-fly-in-the-carbureter epic, found on his return from a trip in the West that he had been appointed supervisor of agencies of the American Locomotive Company. During the trip he established agencies in San Francisco, Seattle, Denver and Minneapolis. From the latter city he telephoned to New York an order from the Twin City Taxicab Company for 85 taxicabs, 10 pleasure cars and two trucks. The order was accepted by telephone.

Washington Oil Tank Finished—The Wayne Oil Tank Company has about completed work on the large tank system in the naval yards at Wasbington, D. C., and it is ready for shipment. The equipment consists of 14 tanks with long-distance pumps. The tanks will be used for the storage of many different oils and preparations, and will vary in capacity from 10 barrels to 1,000 gallons. Iron of a heavy gauge has been used in their construction, and the pumps are a special self-measuring pattern. The whole is pronounced by experts to be a most thorough system.

Fisk Wins in Texas—A set of Fisk tires on an Overland car won the prize offered for tire performance in the 550-mile Dallas-Fort Worth, Tex., endurance run. This car and the Cole pilot car, also a Fisk user, were the only ones to receive perfect tire scores; neither experienced any trouble, nor was it necessary to touch either casings or tubes throughout the run. The contest was over execrable roads, and the fact that tbe winning car crossed the finish line carrying more than 100 pounds of mud, by actual weight, gives some idea of the conditions encountered.

New "Six" from Ohio—The Sebring Motor Car Company, of Sebring, O., announces the 1910 model of the Sebring "Six," a 35-40-horsepower car, selling at $2,750. To try the mettle of the new product a test run was made to New Liverpool on the high gear, witb the gear lever sealed in place. Another car of well-known make which accompanied the local product was forced to change gears repeatedly, but the Sebring took the steep hills on the route without difficulty.

More from South Bend—This hustling Indiana city gets its name in print again through the organization of the Yuster Axle and Transmission Company, capitalized at $100,000. The incorporators and directors are Maurice L. Yuster and Arthur E. Wile, of Rochester, Ind., and Joseph W. Ricketts, of the Ricketts Automobile Company, South Bend. The company has leased a plant consisting of three one-story buildings, which affords facilities for the employment of 50 men.

Lovell-McConnell Enlarges—A new plant is being built by the Lovell-McConnell Company, of Newark, N. J., on a large plot at Wright and Emmet streets, Newark, which it recently purchased. There will be a two-story machine shop, 200 by 50 feet; a foundry, 75 by 40 feet; a fireproof building for storing excelsior; a private garage and a power plant. The Lovell-McConnell Company makes Klaxon horns and other automobile accessories.

Newspaper Science—As an example of the deep technical knowledge of the average newspaper reporter and the resulting product of his busy pencil, we recommend this quotation from the Chicago Journal, November 26, sent us by C. H. Gould. It follows: " . . . was run over and seriously injured in cranking his car. He left the sparker in when he began cranking. The sparker ignited and the automobile started. He was knocked down and run over."

Taking Sugar to Fort Lee—In the Edgewater-Fort Lee hill climb, December 5, a three-ton American truck carried a full load of sugar in barrels up the grade in 5:15. The distance was 3000 feet, and the grade was said to average 17 per cent. The truck took the hill and was not steaming or showing other signs of distress at tbe top. It is to be hoped that the sugar in question was not weighed at the New York custom-house.

Simms Magnetos in England—Reports from across the Atlantic tell of the winning of the $5,000 *Daily Mail* aero prize by J. Moore Brabazon on an aeroplane of his own design, fitted with a Greene motor and Simms magneto. An Indian motorcycle, also fitted with a Simms magneto, recently broke the world's records for 20, 50 and 100 miles on Brooklands track.

Autocar Succeeds the Horse—So successful has been the test made by the Philadelphia postal authorities with the Autocar wagons that last week Postmaster-General Hitchcock secured a contract for four machines, for use on the outlying service. The terms call for a rental of $3,000 a year per car, including the driver. This deal will enable the department to do away with nine horse-drawn wagons.

More Warner Tops—The Warner Pole & Top Company, of Cincinnati, has enlarged its plant about 300 per cent., according to a statement from the company, and will be in new quarters ready for business by January 1. Preparations have been made to take care of an increased business during 1910, and it is expected the output will be 1,000 tops.

To Remedy Parts Shortage—The Stoll Pressed Steel Company, of Buffalo, N. Y., has filed articles of incorporation with a capital stock of $50,000. The incorporators are Daniel H. Stoll, Charles G. Hornung and others. The company will manufacture automobile frames and metal stampings.

Relocation of Buckeye Jacks—Due to increased business it became necessary for the Buckeye Jack Mfg. Co., of Louisville, Ky., to seek larger quarters. The company therefore purchased a commodious plant at Alliance, O., to which it will move about January 1.

IN AND ABOUT THE AGENCIES

Stewart Speedometers, Chicago—A sales office has been opened at 1312 Michigan avenue by the Stewart & Clark Mfg. Co., in order to give prompt attention to the wants of the city trade. Heretofore Chicago patrons have been obliged to go to the factory on Diversey boulevard.

Regal, Pittsburg—Joseph Feicht, who has the Pittsburg agency for the Regal, has taken over the building of the Central Automobile Company, at 5989 Center avenue, and will locate there.

Thomas, Boston—Charles S. Henshaw, Boston agent for the Thomas, has leased the store at 587 Boylston street, and in the future this will be the local home of the Thomas Company.

Great Western, Macomb, Ill.—The Great Western Automobile Company has made arrangements with A. T. Ewing, Son & Deems, of Macomb, to handle the Great Western line.

Stevens-Duryea, Newark, N. J.—A. G. Spaulding & Company have leased the store formerly occupied by H. J. Koehler at 849 Broad street, and will exhibit the Stevens-Duryea.

PERSONAL TRADE MENTION

James W. Gilson, sales manager of the Mitchell Motor Car Company, appeared in a new rôle on Christmas day. He rendered a song of his own composition at the celebration in the Bijou Theater, which was turned over to the poor of the city, and then Mr. Gilson appeared as Santa Claus.

George D. Wilcox, formerly of the Empire Sales Company, of Syracuse, N. Y., has been appointed district sales manager for the Regal Motor Car Company. He will make his headquarters in Syracuse for the present.

WESTERN MOTOR'S NEW MARION PLANT

LOGANSPORT, IND., Dec. 27—There is no industry to-day that occupies such a commanding position as the automobile industry. Its wonderful growth in recent years has astounded the world and put to flight all the conservative ideas of careful business men. This is due to two things—the necessity existing for a means of travel, speedy, reliable, at the constant command of the public, and the fact that the gasoline motor in its present high state of perfection has made this possible.

Manufacturing automobile parts as a business is comparatively new, but today commands the attention and investment of the most progressive men in the world. There is scarcely an automobile placed upon the market that does not profit by the opportunity of securing certain parts manufactured by factories especially devoted to their production, and using these as the means of assembling a perfect car.

The life of an automobile is the motor; without it it is dead. So that the necessity of having a motor absolutely reliable, thoroughly durable, is most apparent. The Rutenber motor, manufactured by the Western Motor Company, stands very high in the estimation of the public as a motor of this character. Built by one of the oldest established firms, it has been in existence practically fifteen years, and is the oldest four-cylinder motor upon the market. This company has its own foundry, making every casting that enters into the construction of the motor, thus avoiding delay or faulty workmanship.

The world's record, made in 1906 by a stock car equipped with a 4½ by 5 Rutenber motor, held good until this present season, when a special racing car, upon an especially prepared track, was able to lower the record. This speaks very well for the every-day qualities of this motor as compared with other regular products.

Miller's New Atlanta Branch

In accordance with his pushing policy to locate a branch office wherever business conditions warrant. The cut above shows the new store recently opened in Atlanta, Ga. This is located at 66 Edgewood avenue, a very favorable location for the automobile supply business. It is to be hoped that branch number nine will fare as well at the hands of the Southern people as its other Northern branches have.

Being absolutely certain of the future of the industry, the Western Motor Company has built a large new factory, following plans furnished by the Kahn Construction Company of Detroit, Mich., at Marion, Ind., and with their two large factories, the other at Logansport, Ind., they will have a production of practically 10,000 engines per year, thus placing them in the foremost rank of motor builders in the country.

The management has been enlarged, each factory being under the supervision of members of the firm, whose experience and ability insure a continuation of the same perfection in design and the same excellent workmanship that has always characterized these motors. The present officers of the company are: F. B. Wilkinson, president; J. F. Digan, vice-president; E. H. Wolcott, secretary; J. Wills Stephenson, treasurer; E. A. Rutenber, mechanical engineer, with a directorate consisting of the same gentlemen and in addition A. C. Barley, C. G. Barley and J. L. Barley.
